Sargassum (Span. sargazo, *sea-weed*). The scientific name of the Gulf-weed, which forms a genus of dark-spored *Algæ* belonging to the natural order *Fucaceæ*, and is characterised by the fruit-bearing receptacles being collected in little bundles in the axils of the leaves; the air-vessels, which are merely transformed leaves, with or without a terminal point, being stalked and separate. The species are extremely numerous, and chiefly tropical or subtropical. We have no species inhabiting our shores, but *S. vulgare* and *S. bacciferum* are occasionally transported to us by the waves. Its abundance over a large portion of the Atlantic has led to the Portuguese expression *mar de Sargasso*, or weedy sea.

Saros. An ancient Assyrian astronomical period, the origin and exact length of which are unknown, though they have been the subject of much disputation. Georgius Syncellus, who wrote in the eighth century, cites a passage from Berosus, reported by Julius Africanus, in which mention is made of three periods—the *Sosos*, the *Neros*, and *Saros*; and the Saros is stated to be 3,600 years. According to Lalande (*Astronomie*, § 1,572), Syncellus also cites Anianus and Panodorus, who assigned the lengths of these periods as follows: The Sossos, 60 days; the Neros, 600 days; and the Saros, 3,600 days, or 9 common years 10 months and 11 days. Legentil, after Fugeres, supposes the Saros to be 10 years; Freret supposed it to be 19½ years; Giraud, 3,600 Julian months, which make 3,711 lunations, or 31 years. Suidas states that the Saros was a period of lunar months equal to 18½ years; and Halley (*Phil. Trans.* No. 194), adopting the same notion, and supporting himself by a passage in Pliny, supposes it to be identical with the lunar period of 18 years, or rather of 223 lunations, which corresponds almost exactly to 242 *nodical* revolutions of the moon [Moon], and consequently brings back the eclipses in the same order. But Goguet (*Origine des Loix*, *&c.*) remarks, that the statement of Suidas is not supported by that of any ancient author; and that there is no reason to suppose that Pliny, in the passage in question, had the Saros in view. By some authors the Saros has been confounded with the *Metonic cycle*. (Sir G. C. Lewis, *Astronomy of the Ancients*, p. 401.)

Sarothamnus (Gr. σάρος, *a broom*, and θάμνος, *a shrub*). A genus of *Leguminosæ*, comprising the common Broom, which bears the name of *Sarothamnus scoparius*, though perhaps better known under those of *Spartium* or *Genista*. The Broom grows naturally in the Canary Isles, Western Europe, and Scandinavia, as well as in Britain, and is applied to various economic purposes. Neat little baskets are made from the twigs divested of their bark in Madeira; and in some parts of Europe the green tops are used as winter food for sheep.

Broom-tops in large doses are emetic and purgative, in small doses diuretic and laxative.

The *Ordre de la Geneste*, or Order of the Broom, was the denomination of an order of knighthood instituted by Louis of France in 1234, and continued till the death of Charles V. The Broom was not less distinguished than the Rose herself during the civil wars of the fourteenth century; for a sprig of the *Planta Genista* was the adopted badge of Geoffrey duke of Anjou, father of Henry II. [Plantagenet.]

Sarpêdon (Gr. Σαρπηδών). There were three persons of this name in Greek mythology, the first being a son of Zeus and Europa, and brother of Minos and Rhadamanthus. He became king of the Lycians [Lycaon; Rishis], and received from Zeus the gift of a life equal in length to three generations. The hero in the Homeric tale of the Trojan war is a grandson of this Sarpedon. With his friend Glaucus (another form of λευκός, *the brilliant*) he goes from his bright, or Lycian, land, to aid Hector at Ilion, where he is slain by Patroclos, Zeus being unable to avert his early doom, although his tears fell in rain-drops from the sky. At the bidding of Zeus, Apollo bathed his body and wrapped it in an ambrosian garment, and Sleep and Death (Thanatos and Hypnos) bore it in the still hours of the night to his home in Lycia, where a great cairn marked his burial-place.

The root of the name (sar, *to go*, Lat. serpo) reappears in the names Hermes and Helen.

The incident which is said to have won for Sarpedon the chieftainship over the Lycians is repeated in the legend of William Tell.

Sarraceniaceæ (Sarracenia, one of the genera). A small group of curious herbaceous Exogens, inhabiting the bogs of North America, and having their leaves hollowed out into tubes or pitchers open at the upper end. Their flowers have some likeness to those of *Papaveraceæ*, to which order they are allied.

Sarsaparilla. The rhizome of various species of *Smilax*. Several varieties of this drug are imported from South America. That which is generally preferred is the reddish fibrous root, known in the market under the

name of *Jamaica* or red sarsaparilla, and referred to *S. officinalis*. What is termed *Lisbon* sarsaparilla, referred to *S. papyracea*, is less fibrous, and more mealy and white in the interior.

This root, though long employed in medicine, seems only lately to have been properly estimated. It was formerly regarded as a specific in syphilis; but this opinion is now given up, and it is used as a powerful and valuable alterative medicine in many disorders of debility, but more especially in those cachectic habits which present symptoms formerly mistaken for venereal—such as pains of the bones, nodes of the periosteum, loss of strength and flesh, and other characters of what is sometimes called a broken constitution. In these cases a course of sarsaparilla has often effected a cure, especially if resorted to in time, when all other remedies, and more especially mercurials, had failed. It must be taken in pretty large doses, i. e. in quantities not less than an ounce to an ounce and a half a day, and persevered in for six, eight, or ten weeks; or a quantity of extract or syrup, or other preparation equivalent to that weight of the dried root. A concentrated liquid extract, and a syrup, are now prepared, which are the best forms. They are apt to disagree with weak stomachs; but generally, by proper management and perseverance, this difficulty may be got over. Where it agrees, the strength is gradually regained, the pains and other symptoms abate and vanish; and the only other effect observed is, either that the bowels are rather more open than usual, or the flow of urine or the perspiration is increased.

Sartorius Muscle. A muscle of the thigh attached at the upper extremity to the edge of the anterior superior spinous process of the ilium, and at the lower to the inner side of the head of the tibia. It is concerned in bending the leg obliquely inwards, and in crossing the thighs; thence called sartorius, or the *tailor's muscle*.

Sash (Fr. chassis). In Architecture, a piece of framing for holding the squares of glass in a window. It is of two sorts—viz. that called the French sash, which is hung like a door to the sash frame; and that in which it moves vertically from being balanced by a weight on each side, to which it is attached by lines running over pulleys at the top of the sash-frame. When in a window both the upper and lower sashes are movable, the sashes are said to be double hung, and single hung when only one of them moves.

Sassafras. The *Laurus Sassafras*, now *Sassafras officinale*, a native of North America, and growing abundantly upon the banks of the river Sassafras; whence its name. It has a warm aromatic flavour, and the decoction is diuretic and diaphoretic. It was formerly used in cases of stone in the bladder (hence its name has by some been derived from saxum, *a stone*, and frangere, *to break*). It has also been extolled as an antisyphilitic remedy, and in rheumatic and cutaneous affections: but it is now scarcely ever employed except as an ingredient in the compound decoction of sarsaparilla.

In medicine various preparations of Sassafras are used in rheumatic and skin affections, generally, however, in combination with other more potent drugs. Sassafras-tea mixed with milk and sugar forms the drink known as Saloop, which is still sold to the working-classes in the early morning at the corners of the London streets. In Virginia the young shoots are made into a kind of beer; in Louisiana the leaves are used as a condiment in sauces, while their mucilaginous properties render them useful for thickening soups.

What is known as Orinoco Sassafras is the produce of *Nectandra cymbarum*, while Cayenne Sassafras is derived from *Licaria guianensis*.

Sassolin. Native boracic acid, from the vicinity of Sasso in Florence.

Satan. A Hebrew word signifying *enemy* or *adversary*; and used as such, without any reference to the Evil Power itself, in one or two passages of the Old and New Testament. The equivalent term in Greek for this word is διάβολος, literally *one who accuses or calumniates*. [Devil; Vritra.]

Satellite (Lat. satelles, *an attendant*). In Astronomy, the name given to the secondary bodies revolving round planets, though to speak more generally the planets themselves are satellites of the sun and each member of a double or multiple star-system comes under the same category.

The planets which are accompanied by satellites are the Earth, Jupiter, Saturn, Uranus, and Neptune. The Earth has one satellite, namely, the Moon; Jupiter has four; Saturn eight; Uranus four; and Neptune probably two. For the Earth's satellite, see Moon.

The Satellites first discovered (leaving the Moon out of the question) were those of Jupiter, first observed by Galileo, and their discovery followed immediately that of the telescope. With a telescope of ordinary power they may be seen (unless when eclipsed by the shadow of the planet, or concealed behind its disc), on any clear night, at different distances from the planet, and arranged nearly in a straight line, in which they appear to oscillate backwards and forwards with different velocities, and performing unequal excursions; so that their arrangement with respect to the planet, or *configurations*, are constantly changing. Sometimes they are observed to pass before Jupiter, in which case they cast a shadow on his disc like a small round black spot, whence they are inferred to be opaque bodies illuminated by the sun; at other times they pass behind the planet, and are concealed from our view; and all these phenomena occur in regular order, and, with respect to each satellite, after the same intervals of time.

From the table it will be seen that the periodic time of the first satellite of Jupiter

is nearly half that of the second, and that of the second nearly half that of the third. The mean angular motions of these three satellites, therefore, form very nearly the progression 1, ½, ¼; so that the mean motion of the first satellite, added to twice that of the third, is very nearly equal to three times the mean motion of the second. Another equally singular analogy is, that the mean longitude of the first, *minus* three times that of the second, *plus* twice that of the third, is always very nearly equal to two right angles. These two results subsist equally in respect both of the sidereal and synodical motions and longitudes; and it follows as a consequence of the last, that for a great number of years at least, the three first satellites cannot be eclipsed at the same time, for in the simultaneous eclipses of the second and third the first will always be between the Sun and Jupiter, and vice versâ.

On account of the shortness of the periods of revolution, the eclipses of the satellites (especially of the first) take place very frequently; and they are phenomena of considerable importance in astronomy, from their affording signals by means of which the differences of terrestrial longitudes are determined, in the same manner as in an eclipse of the moon. The method, however, is not capable of the same precision as is afforded by lunar observations. [LONGITUDE.]

The eclipses of Jupiter's satellites have also an historical interest, from having led Rœmer to the important discovery of the successive propagation and velocity of light. When Jupiter is in opposition with the sun, and his distance from the earth consequently *less* than his distance from the sun by the whole radius of the earth's orbit, the eclipses are observed to happen about 16 m. 26 sec. earlier than when the planet is in conjunction, and its distance from the earth *greater* than its distance from the sun by the same quantity. This phenomenon can only be explained by supposing that light occupies 16 m. 26 sec. in traversing the earth's orbit, and consequently 8 m. 13 sec. in coming from the sun to the earth, which gives a velocity of about 192,000 miles in a second. The theory, with its consequences, has been amply confirmed by Bradley's discovery of aberration. [ABERRATION.]

The satellite in which we are chiefly interested is the moon, which will be found described in its proper place. Below we give, however, the elements of all the satellites of our system. It will be seen that the number of satellites apportioned to each planet is very unequal, Saturn having the largest number, and Venus, Mars, and Mercury being entirely deprived of them. There is reason for believing that some of the satellites both of Jupiter and Saturn possess the same peculiarity as our moon, namely, that their times of revolution and rotation are equal. The elements of the satellites are as follow (the article PLANET should also be consulted):—

Elements of the Satellites.

Satin (Fr.; Welsh sidan). A closely woven silk, generally dressed with gum, especially when intended for ribbons, dresses, &c.

Satin Spar. A fibrous variety of carbonate of lime, which when polished has a lustre resembling that of satin. It is found of snowy whiteness in Buckinghamshire, Cumberland, Devonshire, at Leadhills in Scotland, and elsewhere.

The mineral which is more commonly known by the name of Satin Spar is a much softer stone than the above, being a fibrous kind of Gypsum (a sulphate of lime) found in Nottinghamshire, Derbyshire, Gloucestershire and near Carrickfergus in Ireland. This variety is frequently made into beads and other ornaments, which have a certain kind of resemblance to Cat's-eye; but it is of a much softer nature.

Satin Wood. A handsome Indian wood obtained from *Chloroxylon Swietenia*, and valuable for veneering purposes.

Satire (Lat. satira). In Literature, a representation of vice, or of the ridiculous, either in the form of discourse or put in dramatic action. The word *satire* must not be confounded as to its etymology with the satyri of the Greeks, which were burlesque dramatic pieces, in which the persons represented a band of satyrs. [Drama.] The Latin satira is said to be derived from the *lanx satura*, a dish full of various fruits and herbs which was carried in procession at the feasts of Ceres. Hence the word came to signify a poem full of miscellaneous matter without orderly method, and in this sense only it was probably employed by Lucilius, the first writer of satires, although the title so usurped by him was afterwards applied only to poems of a similar character with his own, viz. containing moral reflection, interspersed with critical touches directed against real or imaginary personages.

Satire, in the literary sense of the word, as designating a species of composition, is usually confined to a species of poetry; but prose works, of which the contents are of a satirical character, are often comprehended under the same appellation. Dramatic writings, also, are not satires in the stricter sense of the word, although their contents may be of a satirical character. According to their subjects, satires are divided into political and moral; and these again severally subdivided into personal and general. Political satires, in almost every language, have been nearly confined to prose; the moral satire alone has found its appropriate vehicle in verse. The only Greek satirist, of whom any fragments have reached us, was Archilochus; and his attacks were evidently directed against individuals. Aristophanes possessed a vein of satirical power, both in the indignant and ludicrous strain, which has never been surpassed; and his dramas contain not only sarcasms on individuals, but also political and ethical lessons of the highest value. But the moral satire, properly so called, was invented by the Romans, not only in form, but in substance, and by them carried to perfection; and it is remarkable that the only species of Roman poetry which has any degree of originality, is that which would seem to have accorded the least with the grave and austere turn of the genuine Roman character.

Of the three Roman satirists whose works have reached us, Horace, the earliest, excels in conveying moral and prudential lessons, in light allusions to the follies or excesses of his time; sometimes, though rarely, assuming the comic character, but generally evincing more of the indefinable quality termed by us humour, than is shown by any other classical writer, with the exception of Aristophanes. Whether the various personages introduced by Horace, for the most part rather as examples to be shunned than as individuals to be held up to laughter or contempt, were intended to represent to his readers, by allusions now undiscernible, actual characters known to them, is a matter not easily ascertainable. The same may be said with respect to Juvenal, whose selected victims are for the most part exalted or notorious personages of the generations immediately preceding his own; and it is not ascertained, although it has often been conjectured, that their names were intended to conceal those of his contemporaries. Juvenal, without either wit or humour, excels in the deep tones of moral indignation befitting the scandalous excesses of the times in which he lived. Persius, although he occasionally rises into very elevated flights of poetry, does not afford many examples of the peculiar excellences of the satirist.

In the literature of modern nations, the fate of satire has been similar to that which has befallen many other species of composition. The name and form of the ancient satire have been preserved by many writers, who have produced, for the most part, little besides cold or exaggerated imitations of antiquity. But the true spirit of satire, in its moral beauty, its humour, and its delicate irony, has been inherited by authors in other classes of literature, who had too much originality of thought to tie down their genius to an antiquated form of writing. Thus in France, Boileau is or was generally cited as the prince of satirists: his satires are closely formed on the model of Horace, and are elegant and correct in style. Besides him, Régnier and many other writers have adopted the same line. But the true satirists of France are Rabelais, in his inimitable romances; Montaigne the essayist, endowed with much of the delicate sarcasm of Horace; and, in later times, Voltaire. So in England, although we possess satirists of considerable merit, who have adopted the form of the ancient satire, our true national satirists are to be found among our essayists and novel-writers. Bishop Hall, in the reign of Elizabeth, and Donne, in that of James, published collections of satires, directed partly against the actual follies or vices of their times, but too closely paraphrased, for

the most part, from the Latin, to admit of much original observation. Withers, among our early satirists, is the only other writer who is at all remembered. Among our modern poets, Pope founded his satires chiefly on the model of those of Horace; but his style and train of thought were rather French than Roman. His works of this class are, in point of form, mere imitations; but they are admirable for their point and the beauty of the verse, and not unfrequently contain pungent personal allusions, without which, unfortunately, a professed satirist can attract little notice and produce little effect. Johnson (in his two well-known imitations of Juvenal), Churchill, and Young, are the latest writers of any note who have composed in the form of the ancient satire. But of all these writers, not one possesses a genuine or national character, except perhaps Churchill; while Swift, Fielding, Dickens, Thackeray, &c., are, in our literature, what Horace and Juvenal were in those of the Romans—although not technically satirists, yet the painters of existing manners, and the representatives of public opinion respecting them. The literary satire, may, perhaps, be mentioned as a separate species of composition, containing either rules of writing, or critical observations on the defects of individual writers. Some of Horace's satires and epistles (as well as his *Ars Poetica*) belong exclusively, others partially, to this class; and have given birth to a series of similar productions, down to the *English Bards and Scotch Reviewers* of Lord Byron.

Satisfaction (Lat. satisfactio). In Law, satisfaction of legacies, portions, and debts, means the donation of a thing with the intention, either expressed or implied, that it is to be taken in whole or part extinguishment of some prior demand. Thus the advancement of a portion by a parent to a child is in certain cases the satisfaction (either wholly or partially) of a legacy, and vice versâ, the presumption being that the child was not intended to have a double provision. And this doctrine has in many cases been extended to gifts of sums of moderate amount which the donors very probably did not really intend should be received as part of the child's ultimate fortune. Again, if a debtor bequeath to his creditor a sum of money equal to or greater than the amount of the debt, this will be considered to have been intended as a satisfaction of the debt.

Satisfied Terms. In Law. In the practice of Conveyancing it is common to limit long terms of years to trustees upon trusts for raising money out of an estate, &c. When these trusts are fulfilled the term is said to be *satisfied*, and it was formerly usual upon subsequent dealings with the property to convey the unexpired residue of such terms upon trust (as it was said) to attend the inheritance, as there were cases in which terms so assigned might be used as a protection by purchasers, mortgagees, &c., against incumbrances of which they had no notice. The statute 8 & 9 Vict. c. 112 put an end to satisfied terms, and consequently to the practice of assigning them.

Satrap (Gr. σατράπης, Lat. satrapa, identified by Michaëlis with the Persian Schahderbân, *the king's door-keeper*). The title given by the Greek writers to the governors of provinces under the Persian kings before the conquests of Alexander. The satrapies of the Persian empire are enumerated by Herodotus, iii. 89. (*Mém. de l'Acad. des Inscr.* vol. xxxi.)

Saturation (Lat. satur, *full*). In Chemistry, a fluid is said to be saturated with a substance when it holds as much of it in solution as it can take up and retain: we thus speak of *saturated solutions* of saline, and other bodies. The term *saturation* is also especially applied to the combination of acids and alkaline or other basic bodies, in such definite proportions as neutralise each other; thus we say that sulphuric acid is saturated by potassa, when neither acid nor alkaline properties are predominant: hence, also, the resulting sulphate of potassa is called a *neutral salt*. An excess of acid would be termed *supersaturation*.

Saturation, Fraction of. The term *fraction of saturation* is used to denote the ratio of the elastic force of the vapour actually existing in the atmosphere, to the elastic force of as much vapour as atmospheric air is capable of containing in an equal volume and at the same temperature, or as would *saturate* the air.

Saturday. The seventh day of the week, held by the Jews as their sabbath. It receives its name from the god Sæter, or Saturn. [SUNDAY.]

Satureja (Arab. Statter, a name for labiate plants). A genus of *Labiatæ* yielding the herb known as Savory, of which two sorts, the summer and the winter, are cultivated, both highly esteemed in cookery for their powerful aromatic flavour. Both species were noticed by Virgil as being among the most fragrant herbs, and on this account were recommended to be grown near beehives. Vinegar flavoured with savory and other aromatic herbs was as much used by the ancient Romans as mint-sauce is at the present day with us. To preserve a supply, it should be cut just before the flowers expand, and dried by exposure to air.

Saturn (Lat. Saturnus). In Astronomy, one of the principal planets in the solar system, and the sixth in the order of distance from the sun. Though less brilliant than Venus and Jupiter, Saturn is nevertheless a conspicuous object in the heavens, and has accordingly attracted the attention of astronomers since the first dawn of the science.

The system of rings with which this planet is surrounded renders it a unique member of the planetary family; and modern investigations tend somewhat to show that we have in it an evidence of the truth of Laplace's hypothesis of the original formation of our system.

This singularity of Saturn's appearance was first noticed by Galileo, to whom the planet

appeared *triple*, or like a large body placed between two small ones. The explanation of the phenomenon was first given by Huygens. In addition to the apparently double ring revealed by the first telescopes, in 1850 a third ring, interior to the two others, was simultaneously discovered in America and this country. The new ring is very faint and dusky; and hence is called the *crape ring*; through it the body of the planet is easily visible. Modern observations have shown not only that this ring is double, but that the two rings first noticed are themselves subdivided into other rings, and that the number and position of the divisions are constantly changing.

When seen through a good telescope, the disc of Saturn appears striped with dark belts, somewhat similar to, but broader, less numerous, and less strongly marked than, those of Jupiter. From their parallelism to the planet's equator, it is inferred that they are probably determined by currents similar to our trade winds.

Saturn is attended by eight satellites; the two nearest the planet and Hyperion can be seen only under the most favourable circumstances, and with telescopes of very high power. [SATELLITE.]

From the circumstances of its casting a dark shadow on Saturn on the side nearest the sun, and receiving the shadow of the planet on the opposite side, it was at first inferred that Saturn's ring is composed of solid ponderous materials. But it also followed that the ring must therefore be under the influence of the planet's attraction, and so was liable to be deranged by the disturbing action of the satellites, the largest of which does not move in the same plane. Hence it became an interesting problem in physical astronomy to determine the conditions under which its equilibrium could be maintained. Laplace showed from the theory of gravitation, that in order to maintain the stability of the ring, it was necessary that the planet's attraction should be counteracted by a centrifugal force arising from a very rapid rotation of the ring in its own plane. Observation has confirmed the result of theory; for from the motions of certain dusky spots on its surface it has been found that the ring revolves in 10 h. 29 m. 17 s., which is very nearly the period assigned by Laplace, and that in which a satellite would revolve at a distance equal to that of the middle of the ring. Laplace also showed that in order to resist the tendency to subversion of the equilibrium, it was necessary to suppose the ring to be of unequal density or thickness in its different parts, so that the centre of gravity might not coincide with the centre of figure; for if it were perfectly similar throughout, its equilibrium would be disturbed by the slightest force, as the attraction of a satellite; and as it would have no tendency to recover itself, it would ultimately be precipitated on the planet. This inequality of form also would seem to be indicated by observation, for it has been noticed that the two arms of the ring sometimes appear to be of unequal length.

Since the time of Laplace this interesting problem has engaged the attention of some of the most powerful analysts. Pierce and Maxwell have by turns shown that the rings cannot be solid and cannot be liquid, and observation certainly endorses these theoretical results, the variations in the divisions of the rings, the, so to speak, birth of the crape ring, and the alleged increase in the breadth of the ring system, are irreconcilable with the assumption of solidity. It has therefore been suggested that the rings may be composed of an innumerable multitude of *satellites*. Mr. Proctor, in a remarkable book recently published (*Saturn and his System*) remarks as follows:—

'The temporary divisions and mottled stripes are easily explained. It is conceivable, for instance, that the streams of satellites forming the rings might be temporarily separated along arcs of greater or less length by narrow strips altogether clear of satellites, or in which satellites might be but sparsely distributed. Divisions of the former kind would appear as dark lines, while those of the latter kind would present precisely that mottled appearance seen in the dusky or ash-coloured stripes. The transparency of the dark inner ring is easily understood if we consider the satellites to be sparsely scattered throughout that formation. The fact that this ring has only become visible of late years no longer presents an insuperable difficulty, for it is readily conceivable that the satellites forming the dark ring have originally belonged to the inner bright ring, whence collisions or disturbing attractions have but lately propelled or drawn them. The gradual spreading out of the rings is explicable when the system is supposed to consist of satellites connected only by their mutual attractions; while the thinness of the system is obviously a necessary consequence of such a formation, for the attraction of Saturn's bulging equatorial regions would compel each satellite to travel near the plane of Saturn's equator.'

The elliptical shading noticed at the ends of the apparent longer axis of the dark ring, is also explained:—

'We have only to imagine that the satellites are strewn more densely near the outer edges of the bright rings, and especially of the inner bright ring, and that this density of distribution gradually diminishes inwards. For instance, we may conclude that along the inner edge of the inner bright ring the satellites are so sparsely strewn that, at the extremities of the apparent longer axis of that edge, *the dark background of the sky becomes visible through the gaps between the satellites*.'

Further particulars of this interesting system will be found noticed under PLANET and SATELLITES. We append in this place the latest values of the dimensions of the ring system, calculated according to both the old and new solar parallax. They are taken from Mr. Proctor's book already referred to.

Longitude of ascending node of ring on the ecliptic	167°	43′	28″·93
Inclination of rings' plane to the ecliptic	28	10	21·95
Annual precession of the vernal equinox of Saturn's northern hemisphere			3·145

Complete revolution of either equinox in 412,080 years

	Miles. Old Value.	Miles. New Value.
Exterior diameter of outer ring	173,500	166,920
Interior " "	153,500	147,670
Exterior diameter of inner ring	150,000	144,810
Interior " "	113,400	109,100
Interior diameter of the dark ring	95,400	91,780
Breadth of outer bright ring	10,000	9,625
" of the division between the rings	1,750	1,680
" of inner bright ring	18,300	17,605
" of the dark ring	9,000	8,660
" of the system of bright rings	30,050	28,910
" of the entire system of rings	39,050	37,570
Space between the planet and dark ring	10,150	9,760

As the plane of the rings is inclined to the ecliptic, and maintains its parallelism during the revolution of the planet, the angle under which it is presented to the sun is continually changing; the appearances which it presents to the earth are therefore also continually changing. The points in which it intersects the ecliptic are in 170° and 350° of longitude; consequently, whenever the planet comes into either of those longitudes (and it must pass through both in each revolution), the plane of the ring passes through the sun, and only the thin edge is illuminated. In this case, the whole quantity of light which is reflected from it is insufficient to render it visible, and it entirely disappears, even in the most powerful telescopes. On the 29th April, 1833, Sir John Herschel records, 'The disappearance of the rings is complete, when observed with a reflector 18 inches in aperture and 20 feet in focal length.' A little before or after the planet is in this position, the ring is seen as a fine straight line of light drawn across the disc of the planet, and projecting on each side. As the planet continues to recede from these points the sun's rays fall upon the ring, and the luminous line gradually opens out into an ellipse, which becomes wider and wider, until it attains its maximum when the longitude of Saturn is 80° or 260°. Now it is evident that the ring will be visible only when the sun and earth are both on the same side of it; and that it will become invisible when its plane passes through the centre of the earth as well as when it passes through the centre of the sun, though for a different reason. On this account two or three disappearances of the ring may happen in a short period of time. The disappearances take place about every 15 years, or half the time of Saturn's revolution in his orbit, and the two sides of the ring have alternately fifteen of our years of sunshine, and fifteen years of darkness.

SATURN. In Latin Mythology, a king of Italy, to whom was ascribed the introduction of agriculture. Saturn thus answers to TRIPTOLEMUS in the Greek legend of Dêmêtêr; and there can be little doubt that the name is connected with the Latin verb sero, satum, *to sow*, while nothing in his attributes corresponds to the Greek Cronos [ZEUS], with whom he has been generally identified. The wife of Saturn, the corngrower, was Ops (*wealth* or *plenty*). Like ROMULUS, Saturn disappeared from the earth when his work was done; and the fancies of mythographers derived the name of the Latin country, Latium, from this disappearance (lateo, *I lie hid*).

Saturnalia. In Roman Antiquities, the festival of Saturn, celebrated about the middle of December, and lasting at different times for one, three, and five days. It was a season of complete liberty and rejoicing. No business was done: friends visited and made presents to each other; and slaves were permitted to jest with their masters, and were waited on by them at table.

Satyr. In Zoology, the orang-utan (*Simia satyrus*, Linn.) is sometimes so called.

Satyrs (Gr. σάτυρος, another form of τίτυρος, *a ram*). In Mythology, beings represented with the heads, arms, and bodies of men, and the lower parts of goats. They were under the peculiar government of Dionysus or Bacchus.

Satyric Drama. In the Greek theatre, a theatrical piece, in which the chorus consisted of satyrs of a semi-burlesque character, as in the *Cyclops* of Euripides. It was customary for the tragedian to present at the same time three tragic pieces and one satirical drama, forming a tetralogy. (Smith's *Dictionary of Greek and Roman Antiquities*, art. 'Tragœdia.')

Saucer of a Capstan. An iron bed or socket bolted to the deck below that on which the capstan is, for the purpose of securing the pivot or spindle on which the apparatus works.

Saucisson (Fr.). [POWDER HOSE.]

Sauer or Sour Kraut. A salted preparation of cabbage much esteemed in Germany, and of which large quantities are prepared for winter use. It is made by shredding the cabbages and packing them in layers in barrels with salt, unground pepper, and a few cloves, the whole mass being firmly pressed down with weights. Partial fermentation sets in, and the watery juice rises to the surface. This expressed juice is after a time poured off, and water containing a solution of salt poured in, and changed from time to time till it ceases to rise with a scum and fetid smell. The cabbage is then fit for keeping, and is stored in the barrels, still under pressure, in cellars, and continues in excellent condition for use till late in spring. When used, it is washed with soft water, and stewed with bacon or salted meat, and is said to be very wholesome.

Saugh. One of the names of the Sallow *Salix caprea*.

Saul or **Sâl.** The Indian name of a valuable timber, much used in the East for building and engineering purposes. The tree which yields it is the *Shorea robusta* of botanists.

Saunders or Sandal Wood. The white or scented sandal wood produced by *Santalum album* and brought from the East Indies. When distilled with water, it yields a thick essential

oil smelling something like roses. Red saunders or sandal is the wood of the *Pterocarpus santalinus*, also a native of India. Its colouring matter is insoluble in water, but soluble in alcohol, and is used to impart a red tinge to certain tinctures. The resinous exudation of this tree constitutes one of the varieties of *dragon's blood*.

Saurians (Gr. σαῦρος, *a lizard*). The name of an order of reptiles, including all those which are covered with scales and have four legs, as the crocodile and lizard. The mouth of the saurians is always armed with teeth, and their toes are generally furnished with claws; they have all a tail more or less long, and generally very thick at the base. A few species, exceptions to the general character, have only two legs. The most gigantic and singular species of the Saurian order are now extinct.

Sauropterygia (Gr. σαῦρος, *lizard*, and πτέρυξ, *fin*). An order of Fossil Reptilia in which are no postorbital and supra-temporal bones: there are large temporal and other vacuities between certain cranial bones; a *foramen parietale*; two antorbital nostrils; teeth simple, in distinct sockets of the premaxillary, maxillary, and premandibular bones, rarely on the palatine or pterygoid bones; maxillaries larger than premaxillaries; limbs natatory; not more than five digits. An episternum and clavicles. A sacrum of one or two vertebræ for the attachment of the pelvic arch in some, numerous cervical vertebræ in most. Pleurapophyses with simple heads; those of the trunk long and bent. The genera *Nothosaurus*, *Pistosaurus*, *Conchiosaurus*, *Simosaurus*, *Placodus*, *Tanystropheus*, *Sphenosaurus*, *Plesiosaurus*, *Pliosaurus*, and *Polyptychodon*, belong to this order, which is found in all the strata from the trias to the chalk inclusive.

Saururaceæ (Saururus, one of the genera). A small order of Hypogynous Exogens, belonging to the Piperal alliance. They differ from *Piperaceæ* in the compound nature of their ovary, and in their constantly stipulate leaves. The species, which have no important properties, are natives of North America, China, and Northern India.

Saussurite. A compact variety of Epidote of a green or ash-grey colour, forming the Jade or Nephrite of the Swiss Alps. Named after De Saussure, by whom it was originally discovered in rounded masses on the borders of the Lake of Geneva. It is also found in Cornwall at Kynance Cove, Coverack Cove, and the Lizard; and in Scotland at Glen Tilt in Perthshire and Portsoy in Banffshire.

Sauvagesiaceæ (Sauvagesia, one of the genera). A small order of Hypogynous Exogens of the Violal alliance, found in South America and the West Indies.

Savannahs (Span. sabana) or **Prairies.** Vast tracts of plain land of small elevation, and generally covered with vegetation throughout most of the year. The prairie land of North America occupies at least two and a half millions of square miles. Part of it is heathy or bushy, part alluvial and wet, but the greater part dry and grassy. The savannahs of the Mississippi are grassy, and occasionally salt effloresces on the surface. The pine barrens of many of the Southern states are similar tracts, barren except for a growth of pine. The interior of Africa contains very extensive tracts of low plain covered with much vegetation, and the resort of large wild animals in enormous herds. These also are savannahs.

Savin (Lat. sabina). One of the species of juniper (*Juniperus Sabina*). It is a low evergreen shrub, of an acrid irritant nature, and possessing purgative, stimulant, and emmenagogue properties.

Savings Banks. The Savings Bank Acts were consolidated and amended by stat. 26 and 27 Vict. c. 87. At the end of 1864 the number of savings banks amounted to 578, and the aggregate amount of their deposits to thirty-nine millions and a half. In addition to these there were about five millions of deposits in the Post Office savings banks. [Bank, Savings.] (Dégerando, *De la Bienfaisance Publique*, vol. iii. 1. 2. ch. iv.)

Savitar. In Hindu Mythology, a name for the sun, as having a golden hand. Like the names Lykios, Lycaon, &c., the word denoted originally only the golden rays which shoot from the sun; but when the name was taken literally, the story grew up that the sun, offering up a sacrifice, cut off his hand, which was replaced by an artificial hand of gold. (Max Müller, *Lectures on Language*, second series, viii.)

Savory. [Satureja.]

Savoy. One of the hardier of the varieties of Cabbage, remarkable for its bullate or blistered leaves. It is the type of a race of subvarieties, included under the name *Brassica oleracea bullata major*.

Saw-wort. The common name for *Serratula*, a genus of Composites represented in this country by *S. tinctoria*, the herbage of which yields a yellow dye.

Saxifragaceæ (Saxifraga, one of the genera). A natural order of Perigynous Exogens, of herbaceous habit, chiefly inhabiting the mountainous regions of Europe and the northern parts of the world. They are nearly allied to *Rosaceæ*, from which they differ in having polyspermous, didymous, partially concrete carpels, and albuminous seeds, and in wanting stipules. The root of *Heuchera americana* is a powerful astringent, whence it is called in North America Alum-root; other species are pretty herbaceous plants.

Saxon Architecture. [Architecture.]

Saxon Blue. A solution of indigo in concentrated sulphuric acid: it is much used as a dye stuff.

Saxony Beryl. A name under which Apatite is sometimes sold by lapidaries.

Scabbard Fish. [Lepidopus.]

Scabinus. The Latinised form of the old German word schöppe, in French échevin.

Judicial officers of various descriptions in the middle ages bore this title, especially in the *communes*, or municipalities. See as to its history, Meyer's *Instit. Judiciaires*; *Mém. de l'Acad. des Inscr.* vol. xxxvii.

Scabrous (Lat. scaber, *rough*). In Botany and Zoology, when a surface is rough to the touch, from granules scarcely visible.

Scævola (Lat. from scævus; Gr. σκαιός, *on the left hand*). An extensive genus of *Goodeniaceæ*, almost peculiar to Australia and the Sandwich Islands. They are herbaceous plants or small shrubs; and one species, *S. Lobelia*, the Taccada of India and Ceylon, commonly found on the seashores of tropical Asia and the islands of the Indian and Pacific Oceans, has a thick succulent stem, full of pith, which is beautifully fine and white, and resembles that of the Rice-paper plant, with which it has been confounded. It is much used by the Malays and Siamese for making artificial flowers, small figures, and other articles used as decorations at feasts and on festivals.

Scaffolding. In Architecture, the temporary combination of timber-work, by the means of upright poles and horizontal pieces, on which latter are laid the boards for carrying up the different stages or floors of a building, and which are *struck* or removed as soon as they have answered their purpose. The scaffolding used for carrying up buildings on the Continent was formerly more scientifically and solidly constructed than that used in this country. But great improvements have latterly taken place in our practice; and instead of the poles lashed together with ropes which were formerly used, squared timber properly bolted is now employed, so as to constitute a framework that will carry a travelling crane on the top. This crane or winch is often now worked by steam.

Scagliola (Ital.). In Architecture, a composition; sometimes called also *Mischia*, from the mixture of colours employed in it to imitate marble. The Florentines claim the invention of this art, but it had been practised in Lombardy previous to its introduction at Florence. Lanza says that it was invented by Guido Sassi, who died in 1649, at Carpi, in the state of Modena, and that he commenced by executing cornices and other members of architecture which had all the appearance of the finest marbles; whereas its introduction at Florence was not till the middle of the eighteenth century. Scagliola is composed of gypsum or sulphate of lime, calcined and reduced to a fine powder, with the addition of which to water a fine paste is made. When columns are made with the composition, a frame or cradle is first formed, which is lathed round and coated with lime and hair, raised up in some parts with small projections. On this, when dry, is laid a composition consisting of pure gypsum, calcined and passed through a sieve, and, as wanted, mixed with glue or isinglass; it is floated with wooden moulds of the proper form, during which operation the colours, by which the imitation is obtained, are put on. When this is set, the work is smoothed with pumice-stone with one hand of the workman, while the other is employed in washing it with a sponge and water. It is then polished with tripoli, charcoal, and a piece of fine linen, and afterwards with a piece of felt dipped in oil and tripoli, and finished off with pure oil laid on with cotton wool.

Scalar (Lat. scala). In the language of Quaternions, a positive or negative number. [QUATERNION.]

Scald (Norse skálld). In the old Norse language, a poet. In the northern literature, those mythological poems of which the writers are known are properly called songs of the Scalds, while those of unknown authors are termed Eddas. It appears from Tacitus that the ancient Germans had those three classes of poems which were found at a later era in Scandinavia, namely, relating to the gods, to heaven, and to historical subjects. The Scalds whose remains have come down to us are very numerous. Their poems are partly alliterative, and partly rhymed; and this latter circumstance seems to indicate works of comparatively recent date. The historical value of their poems is considerable; but they are written in a peculiar vein of exaggeration, and in a metaphysical and almost enigmatical fashion, which appears to have been characteristic of the poetical art of the north. [EDDA; SAGA.] A list of the Scalds, with remarks on Scaldic poetry, is given in the *Fundgruben des Orientes*, vol. i.

Scale (Ital. scala, *a ladder* or *series of stairs*). In Mensuration, a line or rule of a definite length, divided into a given number of equal parts, and used for the purpose of measuring other linear magnitudes. The term *scale* is also applied to a mathematical instrument, consisting of an assemblage of lines and figures engraved on a plane rule, by means of which certain proportional quantities or arithmetical results are obtained by inspection. Of these the principal are the *plane scale*, the *diagonal scale*, *Gunter's scale*, &c. For the construction and uses of these various scales, see Robertson's *Description and Use of Mathematical Instruments*.

SCALE. In Music, a progressive series of sounds rising or falling through such intermediate degrees as create an agreeable and perfect succession, wherein all the harmonical intervals are conveniently divided. The diatonic scale has seven notes in each octave, the intervals being whole tones and semitones, arranged in the proper order according as the mode is major or minor; the chromatic scale has twelve notes, the intervals being all semitones.

SCALE. In Zoology, this name is properly applied to the plates, generally thin, small, and imbricated, which defend the skin of fishes. They are substances of different texture which are developed beneath the true epiderm, and

appertain to the system of the rete mucosum. The so-called scales of serpents and other reptiles are modifications of the epidermis, and are sometimes termed *scutes*. Fishes have been classified according to the structure of their scales. [CTENOID; CYCLOID; GANOID; PLACOID.]

SCALE. The hard crust of salt, lime, &c., which collects upon the inner surface of the plates of a boiler, when proper attention has not been paid to the *blowing off*. The hammers that are used for detaching this scale are specifically known as *scaling hammers*.

Scale of Notation. In Arithmetic, numbers are represented by *numerals* placed side by side, which numerals have an *intrinsic* as well as a *local* value. By the scale of notation is meant the order of progression of these local values. Thus, in the ordinary or *denary scale*, the value of the unit as we proceed from right to left increases in the ratio of one to ten. The ratio is called the *base* or *radix* of the scale. [ARITHMETIC.]

Scale of Relation. [RECURRING SERIES.]

Scales for Weighing. [WEIGHTS AND MEASURES.]

Scalene Triangle (Gr. σκαληνός, *unequal*). In Geometry, a triangle whose sides are unequal.

Scalenus (Gr. σκαληνός). A muscle of the neck, situated between the transverse processes of the cervical vertebræ and the upper part of the neck.

Scaling Ladders. Ladders made in parts of about twelve feet in length, which can be joined together by inserting the end of one portion in staples at the end of another, and securing them by lashings.

Scallop. A bivalve mollusc, the *Pecten maximus* of malacologists. An allied species, the *Pecten Jacobæus*, was much employed by pilgrims during the middle ages, as the emblem of St. Iago de Compostella. Many species of scallops are known, some of great size and beauty, which are found in the Pacific seas.

SCALLOP. In Heraldry. [ESCALOP.]

Scalpel (Lat. scalpare, *to carve*). A dissecting knife.

Scalpriform (Lat. scalprum, *a knife* or *chisel*). Certain teeth are so called, which have a cutting edge, preserved by a partial deposition of the enamel on one side: such scalpriform teeth are large, long, and curved, and are well exemplified in the incisors of the Rodent order.

Scalprum (Lat.). In Mammalogy, the cutting edge of the incisor teeth.

Scammony. In Pharmacy, the gum-resin of the *Convolvulus Scammonia*, chiefly imported from Aleppo and Smyrna in packages, called *drums*, weighing about 100 pounds each. It is of a dark olive colour, and when wetted and rubbed should easily form a milky solution: it is very apt to be adulterated, and an article entirely fictitious is often sold under the name of scammony. Scammony is an excellent drastic purge, and is generally administered in combination with other purgatives in doses of three or four grains, or more.

Scandalum Magnatum. In Law, an action which still lies, although for a long period it has never been resorted to, on the stat. 2 Rich. II. stat. 1, c. 5, and statute of Westminster the First, 3 Edw. I. c. 34, for words spoken in derogation of a peer, a judge, or other great officer of the realm; which need not be such as would be actionable at common law in the case of a private person. 'The duke of Richmond *v.* Castellow,' in the eighth year of Queen Anne, seems to have been the last instance of this species of action.

Scanning. In Prosody, the measuring of a verse by feet, according to the quantity of the syllables. [PROSODY.]

Scansorials (Lat. scando, *I climb*). Climbing birds. The name of an order of birds, including those which have the toes arranged in pairs, two before and two behind; a conformation of the foot which is well adapted for the act of climbing.

Scant. In Naval language, the term applied to the wind when it is barely fair.

Scantling (Fr. échantillon). In Architecture, the measures of breadth and thickness of a piece of timber or other material. It is also the name of a piece of timber when under five inches square.

SCANTLING. In Naval Architecture, the scale or dimensions of the breadth and thickness of the timbers. Thus two ships of different sizes may have the same scantling.

Scape (Lat. scapus, *a stem*). In Botany, a peduncle, which, in plants destitute of a stem, rises above the ground and supports the flowers upon its apex, as in the Cowslip.

Scape Goat. In the Levitical legislation, a live goat on which the high priest was enjoined to lay the iniquities of the Israelites, which the goat, being set free, was to bear into a land uninhabited. (Lev. xvi. 21.)

Scapellus (dim. of Lat. scapus). In Botany, the neck or caulicle of the germinating embryo.

Scapement or **Escapement.** [HOROLOGY.]

Scaphite (Gr. σκάφη, *a boat* or *skiff*). A genus of elliptical-chambered shells, belonging to the family of the Ammonitidæ, having the inner extremity coiled up in whorls embracing one another, and the outer extremity continued nearly in a horizontal plane, and then folded back, so as sometimes to touch the spire of the opposite end of the shell. The transverse plates are numerous, and are pierced by a marginal siphuncle at the back of the shell, and their edges are deeply cut and foliated. These beautiful shells, which thus resemble the ancient form of a boat, are almost peculiar to the chalk formation.

Scapolite (Gr. σκᾶπος, *a rod*, and λίθος, *stone*). A silicate of alumina and lime, originally from Arendal in Norway, the crystals of which are often collected in groups of parallel

diverging, or intermingled prisms (whence its name). It is generally of a pale colour; either white or grey, yellowish, blue, green, or red, and transparent or translucent.

Scapula (Lat. *the shoulder-blade*). In Comparative Anatomy, the bone which passes from the shoulder joint in a direction towards the vertebral column. It is broad and flat, generally triangular, sometimes subquadrilateral, in the mammalia; narrow, and commonly sabre-shaped, in birds; narrow and straight in Saurian reptiles; a round, strong, and straight column, in Chelonian reptiles; variously shaped, and articulated to the back of the skull in most fishes.

Scapulars or **Scapular Feathers.** In Ornithology, the feathers which take their origin from the shoulders and cover the sides of the back.

Scapulary (Lat. scapulæ, *the shoulders*). A portion of the dress of the monastic orders, consisting of two bands of woollen stuff, of which the one crosses the back or shoulders, and the other the stomach. According to the Abbé Fleury (*Mœurs des Chrétiens*), the scapulary originated with St. Benedict, and was a large and heavy covering of the shoulders, worn by the early monks in their rural labours for the convenience of carrying loads, and to protect the tunic. Simon Stock, an Englishman, general of the Carmelites in the thirteenth century, first introduced, under the authority of a vision, the notion that the scapulary is an especial sign of devotion to the Virgin Mary. The scapulary of lay persons consists of two little pieces of stuff on which the name of the Virgin is embroidered.

Scapus (Lat.; Gr. σκᾶπος, Doric form of σκῆπτρον, *a shaft* or *stalk*). In Architecture, the Shaft of a column.

Scapus. In Ornithology, the stem or trunk of a feather, including the hollow base or quill, *calamus*, which is inserted into the skin, and the solid exserted stem supporting the barbs, or *rachis*.

Scarabæidans (Lat. scarabæus). The name of a family of Coleopterous insects, of which the genus *Scarabæus* is the type; it corresponds with the great tribe of Lamellicorns.

Scarabæus (Lat.; Gr. σκάραβος, and κάραβος, *a beetle*. The word is akin to Sansc. çarabha, *a locust*; Ger. krebs; Eng. crab). The use and meaning of the scarabæus, as a symbol, are, as yet, among the mysteries of archæological science. The Egyptians, it is said, found in it an emblem of the world instinct with the seeds of life; because the kind of beetle represented by it forms a ball of earth in which to deposit its eggs. It is also called a type of the sun. However this may be, it was habitually worn by the ancient Egyptians and Etrurians as an amulet. The ancient Egyptian scarabæus was plain, or inscribed with characters; and was made of opaque stone, basalt, or porphyry. The Etrurian scarabæus (found in quantities in the sepulchres) was of semitransparent stone, cornelian, onyx, sardonyx, agate, or jasper. Lastly, the modern Egyptian scarabæus of Roman times was generally of precious or semi-precious stones, and rudely engraved, and seems to belong to an age when, the religious use of the scarabæus being forgotten, it was retained only as an ornament.

Scaramouch (Fr. escarmouche, Span. escaramuza, Ital. scaramuccio, *skirmish*). A personage in the old Italian Commedia dell' Arte, dressed in the Spanish or Hispano-Neapolitan costume, and representing a military personage, a poltroon and braggadocio, who always ended by receiving a beating from the hands of Harlequin. The most celebrated Scaramouch of the Italian theatre at Paris was Tiberio Fiurelli, a Neapolitan, whose agility was such that he was able, according to his biographers, to give a box on the ear with his foot at the age of eighty.

Scarbroite. A clay-like mineral found in a calcareous rock near Scarborough (whence the name) in Yorkshire, between septa of ironstone. It is a hydrated silicate of alumina, and occurs in amorphous, pure white masses which are devoid of lustre and give off a strong argillaceous odour when breathed on.

Scarfing. In Architecture, the formation of a beam out of two pieces of timber; usually employed when it cannot be conveniently procured in one length. It is usually performed by cutting the ends obliquely, indenting the faces where they are joined to each other, and bolting them through the tapering ends when brought together.

Scarfskin. The cuticle or epidermis. [Skin.]

Scarificator (Lat. scarifico, Gr. σκαριφάομαι, *I scrape* or *scratch*). An instrument used in cupping; it consists of ten or twelve lancets, which are discharged through apertures in its plane surface by pulling a kind of trigger, so that in passing they make a number of incisions in the part to which the instrument is applied.

Scarlatina or **Scarlet Fever.** This highly contagious disease assumes several different forms. These are ushered in with fever varying in intensity, sometimes very slight, occasionally violent, but in some forms of the disease adynamic from the commencement, and apparently indicative of the action of an animal poison. In most cases a scarlet efflorescence appears on the second day upon the skin, and in three or four days the cuticle peels off in branny scales. Old writers speak of the fourth day for the appearance of eruption, but it is not so. The throat, though generally severely involved, may escape altogether in mild cases, but in the virulent forms of the disease it may become inflamed, livid, and even gangrenous.

Scarlatina, even in its mildest forms, is occasionally followed by general dropsy, but this condition admits of relief.

Scarlet fever is distinguished from measles by the greater extent and want of elevation of the eruption, and by its not congregating into semilunar patches; nor is there the cough, and

running from the eyes and nose, which usher in the measles. It seizes persons of all ages, but children and the young are most subject to it. It appears at all seasons of the year, and in autumn is often epidemic. It may attack the same person more than once. The malignant sore throat of the older writers (*cynanche maligna*) is nothing else than scarlatina in its worst form, and in which the virulence of the disease is extended to the throat.

Scarlet Oak. *Quercus coccinea*, the leaves of which turn red in dying.

Scarlet Runner. The *Phaseolus multiflorus*, which is extensively cultivated in this country as an esculent. [PHASEOLUS.]

Scarp. [ESCARP.]

Scarus (Lat.; Gr. σκάρος). The Parrot-fish, so called, in which the dental apparatus is developed in a bony beak. The species so called by the ancients exists in the Mediterranean.

Scelides (Gr. σκέλος, *a leg*). In Mammalogy, the lower, posterior, or pelvic extremities.

Scelotyrbe (Gr. σκελοτύρβη, *lameness in the leg*). A disease described by Galen, in which a man is incapable of walking straight forward, and drags the foot: it is generally regarded as a species of Chorea, or St. Vitus's dance.

Scene (Gr. σκηνή, *a covered place*). In Dramatic Literature, the imaginary place in which the action of the play is supposed to pass; also a division of a drama: properly speaking, whenever the action changes to a new scene or place. But in the French theatre, and those framed on its model (in which unity of place is observed), every entry of an actor constitutes a new scene. On the English stage, the subdivision called a scene is extremely arbitrary; the scenes in most plays being far more numerous than the actual changes of scene, while at the same time the French rule is not observed, and actors enter in the middle of a scene. The scenes in a play are numbered as subdivisions of the act. [ACT.]

Scene Painting. A department of the art of painting, governed by the laws of perspective, applied to the peculiar exigencies of a theatre. It is conducted chiefly in distemper or water colours, and admits of the most striking effects, which indeed, in scene painting, is almost all that is required.

Scenery (Gr. σκηνή, *a covered place*, hence a stage: in modern Greek the word has acquired the meaning attached by us to the term *scene*). The appearance of a place or of objects, or the representation of a spot wherein an action is performed. [LANDSCAPE.]

Scenery, Celestial. [SIDEREAL SYSTEM; SOLAR SYSTEM.]

Scepaceæ (Scepa, a name of one of the genera). A group of Diclinous Exogens, referred by Lindley as a separate order to the Euphorbial alliance, and by others united with the *Euphorbiaceæ*. The characters relied on for their separation are, the amentaceous male flowers, the definite suspended anatropal ovules, and the superior radicle. *Scepa*, the typical genus, is now merged in *Aporosa*.

Scepticism (Gr. σκεπτικός, *thoughtful*). In the History of Philosophy, a name sometimes given to that tendency of thought or system of doctrines the object of which is, by denying the existence of all grounds of knowledge, to introduce universal doubt and suspension of assent. Schools of scepticism have existed at several different periods in the progress of philosophical enquiry. The first who received or adopted the name was Pyrrho, who taught in Athens about the year 300 B.C. Our chief notices of his opinions are derived from the writings, in verse, of his disciple Timon, preserved to us by Sextus Empiricus. He was led to his sceptical views partly by the contradictions observable in the impressions on our senses, and partly by the incompatibility of the principles of different schools with each other. To a complete suspension of judgment in speculation (ἐποχή) he united a corresponding state of indifference in feeling (ἀταραξία), and made virtue and happiness to consist in the absence of mental perturbation. Either he or his scholars endeavoured to present a synopsis of their sceptical views in ten general forms, or commonplaces, all of which, however, may be included in one or other of the two sources of doubt mentioned above.

The school of Pyrrho seems to have expired with his disciple Timon; though many of his views were espoused and maintained by the later academy. [ACADEMICS.] About the middle of the third century of the Christian era, we meet with a school known as that of the later sceptics. This sect seems to have originated with one Ænesidemus, a physician. It was, in fact, a school of physicians, who, in opposition to the *Methodic* sect, adopted a strictly empirical mode of treatment, and sought in sceptical considerations a justification of their practice. The grounds of this scepticism have been recorded by Sextus Empiricus. It regarded not so much the validity of the notices given by the senses (to which their empirical method imposed on them a necessity of yielding their assent), as the general form and method of science. Syllogism they regarded as utterly void, inasmuch as the conclusion must have been contained in the induction on which the major proposition was founded. Perfect induction was impossible; imperfect induction was unsatisfactory. They also attacked, with considerable acuteness, the received doctrines of cause and effect, and of the nature of God; chiefly in opposition to the Stoics, the most dogmatical of the ancient sects. Their morality, like their speculative creed, was a system of mere sensualism. This school may be considered as the last purely Grecian sect. After them an Oriental element was introduced into philosophy, which materially altered its character and bearing. The most celebrated sceptics of modern times are Montaigne (A.D. 1580); Glanville, an English-

man, who flourished about the period of the Restoration; Bayle, and Hume. According to Hume, all the objects of consciousness may be reduced to two classes: 1. the impressions on the senses; and, 2. ideas or copies of those impressions, which differ from their original only in being less vivid. All knowledge, save that of mathematical relations, consists in the arrangement of these impressions according to the order of their succession. Of the connection between any two links of this succession, we know nothing; that to which we give the name causation being, in fact, nothing more than habitual sequence relatively to the phenomena, and custom, or often-repeated association, in relation to ourselves. All enquiry into things in themselves, or their grounds—in other words, all metaphysical speculation, is consequently founded on delusion. The writings of David Hume, which contain his sceptical speculations, are his *Treatise on Human Nature*, and the early part of the second volume of his *Essays*. (Ritter, book x. ch. i.; Hallam, *Literary History*, part ii. ch. iii.)

Sceptre (Gr. σκῆπτρον, *a staff to lean on*). A well-known emblem of sovereignty. Achilles swears by his staff or sceptre in the first book of the *Iliad*. Tarquin the elder is said to be the first who assumed the sceptre among the Romans. According to Justin, it was originally a spear. The sceptre of the Merovingian kings, as represented on monuments, is a rod, probably of metal, of the height of the bearer, and slightly curved like a crosier.

Schaalstein. A Mineralogical synonym of *Table Spar* (Tafelspath of the Germans). [Wollastonite.]

Schapziger. A kind of cheese made in Switzerland, to which the coumarin flavour of *Melilotus cœruleus* is communicated.

Schedule (Lat. dim. of scheda, Gr. σχίδη, *a piece cut off*, hence *a leaf of paper*). In the language of English Jurisprudence, this term is commonly used to signify some smaller document attached to a larger one and forming for legal purposes part of it; as the *schedule* to an Act of Parliament, in which various particulars to which the general provisions of that Act relate are enumerated; the *schedule* or inventory of goods attached to documents dealing with them; and so forth.

Scheele's Green. A green pigment obtained by mixing arsenite of potassa with sulphate of copper. It is an arsenite of copper, and much used as an oil and water colour, and more especially for paper-hangings: but the frequent occurrence of its mischievous effects when thus employed has lately thrown it into disrepute. 'From a shop the walls of which were covered with arsenical paper, I procured some dust which yielded a large proportion of arsenic. In another case arsenic was found in the dust on the cornices and picture frames. It is therefore obvious that the atmosphere of rooms may thus be contaminated, and the poisonous particles received into the lungs, and though the quantity thus imbibed at any one time may be small, it is certainly not advisable that, merely for the sake of a green colour, persons should be exposed to breathe arsenic day by day.' (Taylor *On Poisons*.)

Scheeletine. Native tungstate of lead, composed (when pure) of 51·7 per cent. of tungstic acid, and 48·3 lead. It occurs in faintly translucent four-sided prisms, which are colourless or of a yellowish-grey, brownish, or green colour, in the tin-mines of Zinnwald in Bohemia, at Bleiberg in Carinthia, and near Coquimbo in Chili. Named after the Swedish chemist Scheele.

Scheelium. A name sometimes applied to tungsten, in honour of Scheele, who discovered it.

Scheererite. A mineral resin found in loosely aggregated, feebly shining, crystalline grains and folia, or in minute acicular crystals with a yellowish or greenish tinge, in small cavities in Brown Coal at Utznach in Switzerland, and in Denmark in peat-mosses. Named after the discoverer, Colonel von Scheerer.

Scheiks. The hereditary chieftains of the Arab tribes. The descendants of Mohammed hold the highest rank among the scheiks, and are distinguished from the other chiefs by the title of Sherif.

Schelling, The Philosophy of. This philosophy teaches the identity or *indifference* of the ideal and real. Its author, Frederick Wilhelm Joseph von Schelling, was born Jan. 27, 1775, and studied successively at Tübingen, Leipzig, and Jena. In the latter place, he was a pupil of Fichte. In 1841 Schelling went to Berlin, where his lectures excited the most lively interest. He died in 1854.

It is extremely difficult to understand the true significancy of any particular system of philosophy, if it is considered in itself, and apart from its connection with the general history of philosophy. This general truth is particularly applicable to the philosophical developement of Germany, the unity of whose literary pursuits seems to supply the want of a true political unity. The concatenation of views and opinions, from Leibnitz and Spinosa to the philosophers of the present day, is easily traceable; but it will be sufficient for the elucidation of Schelling's philosophy to begin with the critical theory of Kant. The transcendental idealism of this philosopher formed the transition from the empiricism of the eighteenth century, and effected, as it were, a compromise between the scepticism of Hume and the realism to which it succeeded. Without denying or asserting the existence of a material world, Kant was content with confessing an ignorance, at all events, of its nature. In his view, all that man can know of outward objects is, that they furnish the material ground of his conceptions. Of things themselves, or, as Kant calls them, of phenomena, man absolutely knows nothing; all that he can do is to note the modes under which they appear to him.

But while the criticism of the pure reason seemed to lead to a speculative idealism, that of the practical reason appeared to possess a mystical tendency. This tendency of the Kantian philosophy was worked out by Haman and Herder, but found its culminating point in Jacobi's Philosophy of Faith, which had many adherents in Germany, and extensively influenced the prevailing ideas of philosophy. According to Jacobi, the end and aim of true philosophy is a knowledge of God. Now, the pursuit of this object must set out from feeling and intuition, for there is no speculative method which can give a demonstration of God; for God is infinite, but the understanding finite; and all mediate knowledge by reasoning, which is a procedure of the intellect, cannot attain to the infinite. Reasoning, moreover, cannot do more than establish the correspondence of certain identical propositions from which it passes, step by step, and on the presumption of whose truth it proceeds. The element, therefore, of all human knowledge is faith; an original instinct of man's nature, which immediately reveals to him the divine; and, in spite of any suspicions of the validity of sensuous testimony, enforces a belief in the existence of an external world. The philosophical merits of Jacobi consist in this, that he did not, with Kant, regard God as a mere abstraction, but as a living spirit, whose presence is manifest within man himself; and further, in the way that he insisted on the validity of the immediate perceptions of consciousness, in opposition to the absolute authority of the finite understanding. However, true philosophical science cannot admit of any such contrariety of intellect and feeling; and to establish their identity, or at least to combine them in unison, was the problem which Fichte attempted to solve. Fichte's philosophy is marked chiefly by the way in which he carried, to its extreme result, the idealistic tendency of Kant. In the *Wissenschaftslehre* we have a system of pure and absolute idealism. The existence of a material world is here denied unconditionally; the real exists only so far as it is necessarily conceived by us; so that the external world is purely a creation of our conceptions, and the real is a product of the ideal. To use the language of Fichte, the ego is absolute, and posits itself; it is a pure activity. As its activity, however, has certain indefinable limits, when it experiences this limitation of its activity it also posits a non-ego, and so originates the objective world. The ego, therefore, cannot posit itself without at the same time projecting a non-ego; which, consequently, is in so far the mere creation of the ego. With the mediate knowledge of reflection, by which Fichte attained to this speculative result, he combined for practical ends the authority of immediate consciousness. As, he argued, it is from the impulse of the ego to activity that the non-ego arises, the absolute ego stands to the intelligent ego in the relation of a cause to its effect. But although the absolute practical ego is absolutely free, and the sole principle of all reality, so as to posit the world in opposition to itself, and to be its cause, it has, nevertheless, a subjective limit to its operation. This is the idea of duty which the consciousness immediately announces to man as an unconditional authority and obligation; which, however, is not subversive of the freedom of the ego, but is simply an impulsive motive to its activity. Now, so far as the ego attempts to realise this duty, it tends to a moral order. He who does his utmost to establish this moral order, comes near to the Deity, and enters upon his true and proper life.

Such was the point to which speculation had attained when Schelling appeared as a philosophical writer. The subjective thought had been made the supreme and only principle, before which all objective entity was driven into the background; and the subjectivity of the idea was the only real existence acknowledged. For this subjective idealism Schelling, however, did but substitute an objective idealism, by giving objectivity to the idea itself, and declaring every entity to be also rational thought. Kant had spoken of the objective as unknowable; Fichte had denied its existence; and Schelling identified the ideal and the real. Fichte had confined himself to giving a derivation of nature and its laws out of an absolute and spontaneous activity of the ego. Schelling maintained that not only must the laws of consciousness be immediately cognisable in the objective world, as laws of nature; but conversely, also, the laws of nature must be immediately demonstrable in the consciousness as laws of the subjective. Man finds himself in nature, and nature in himself. Besides Fichte's method, therefore, of descending from the ego, Schelling held it to be necessary to ascend from nature up to ego. The former method is given in his transcendental philosophy, the latter in the *nature-philosophy*, which make up his system of identity. The general principles of this system are as follows: That true and perfect science, which it has always been the object of philosophy to realise, must be one which has its authority in itself, embraces all things, and is perfectly correspondent to its object; for truth is impossible without a perfect agreement of the knowing and the known. Now, as all philosophy must proceed on the assumption that the cognisant mind is capable of true cognition, it follows that the knowing subject cannot, in its essence, be opposed to the object known; and that, consequently, it must be possible to know the real essence of things. The essence, therefore, of that which thinks and that which exists, of thought and entity, soul and body, is one and the same. By means of this essential oneness, or, in the terminology of Schelling, of this absolute identity and in-

difference of thought and being, the ideal and real, and in consequence of the mind being, in substance at least, homogeneous with things without it, the former is capable of representing in cognition the latter, such as they are in truth and in their essence. The knowledge thus gained is a pure intellectual intuition; it is not mere reflection, which, by its nature, cannot go beyond its data. Rising above phenomena to the ideas of the absolute, which is their identical origin, it is able to apprehend the essence of things. It is, however, by reflection that man becomes conscious of these ideas through the aid of the senses; and this art of unfolding ideas by reflection constitutes Dialectics. One of the duties of this art is to trace the identical principle in its regular developement, and to determine every branch of knowledge, in relation not only to the fundamental idea of the truth, but also to the cognate sciences. The true method of philosophy is the method of construction, and without it no safe step can be taken in speculative science. This method is to become fully conscious of the laws of mind, which are inherent in it; and, agreeably to them, to shape every special science conformably to the existence of things. By such a method philosophical science is possible; and this is a science of the existent agreeably to the ideas (*Wissenschaft von Ideen*), i.e. a science of God, and of His relation to the world, and of man and nature. According to the *nature-philosophy*, the Absolute, or God, is both thought and entity, without either unity or difference, out of which all contrariety has proceeded, and into which it will again return. As the Absolute is the sole and eternal essence of all things, every true entity, and therefore nature also, is divine, without a participation in which there can be no existence. In the eternal generation of things, the Absolute has revealed itself in infinite ways in space and time. This revelation is a living developement of the infinite according to certain contraries of the subjective and the objective, the ideal and the real. These contraries strive to combine together in different proportions, and so acquire different names, according to the varying preponderance or polarity of the ideal and real. Things, consequently, are not different in their essence, but merely quantitatively, or in degree. The preponderance of the objective constitutes unconscious nature: that of the subjective is spirit. The more complete the combination of these contraries, the more perfect are the objects. The most perfect union of them, or their absolute indifference, is found in the universe; and this complete identification and reunion of them is the full revelation of God. Man, lastly, is a copy of the universe (*microcosm*), in so far as, in a manner of his own, he unites together the ideal and the real.

The philosophy of Schelling appears, then, to be directly opposed to that of Kant, from which, however, it is directly descended not only in the nature of the knowledge which it assumes to be possible, but also with respect to the objects of that knowledge. In its essence it pretends to give a true image of the object known, and embraces, therefore, both nature and the world of man and spirits. In its method of exposition, also, it pretends to imitate the true course of the developement of nature, in which everything passes by coherent and successive steps (or *powers*, A, A^1, A^2, &c.) from the undeveloped to the developed and the perfect; and, beginning from the lowest grades of entity, passes to its higher developements.

Such is an outline of the system of Identity, as propounded by Schelling upwards of forty years ago, and which has exercised so important an influence on the mind of Germany. There is, however, good reason to believe that the opinions of its author were in his later years materially modified.

A brief statement of the manner in which the theory of Schelling was further modified by Hegel may be appended here, and will complete it as a general view of the modern philosophy in Germany. In the *Encyclopædia of Philosophical Sciences*, which Hegel published in 1817 at Berlin, and designed as a manual for the use of his class, he gives a general view of his system, and clearly exhibits its ultimate tendency. 'Logic,' he says, 'is the basis of ontology.' The idea in itself and potentially is the primary substance, but *in actu* it passes into the real. The ideal is to be examined, 1st, subjectively, as it exists in the mind; 2nd, objectively, or in *other*, i.e. in its outward manifestation; and 3rd, absolutely, as it is realised in art, religion, and philosophy. Schelling had made triplicity in unity to be the law which the principle of identity follows in its outward developement, and this trinary law forms also a conspicuous element of the Hegelian system. Thus he makes thought to be threefold: 1. *Formal thought*, which is independent of all subject matter, or, in the language of Hegel, of *all contents*; 2. The *notion*, or thought more fully determined; 3. The *idea*, or thought in its totality and fully determined. The last is the concrete, which is a self-developing and organical system, containing in itself all *momenta* or germs of further developement. Philosophy is the right evolution of this concrete, and its true method is the dialectical momentum. The history of philosophy, apart from its accidental media of schools and professors, is nothing less than the actual developement of philosophy itself. The several systems successively recorded are but so many gradations of progress, and the latest system is the sum and perfection of all anterior ones. Thus the theories of Schelling and Hegel are essentially based on the same principle, the absolute identity of thought and being. According to the former, the mind is in full possession both of truth and reality, the knowledge of which it attains by self-conscious-

ness, in the intellectual intuition. For the latter, Hegel substituted his *dialectical momentum*, or the logical developement of the idea. (Michelet, *Geschichte der letzten Systeme der Philosophie in Deutschland*; Jacobi, *Briefe über die Lehre des Spinosa*; Fichte, *Die Wissenschaftslehre*; *Die Bestimmung der Menschen*; Schelling, *System des transcendentalen Idealismus*; Bruno, *Oder über die göttliche und natürliche Princip. der Dinge*; Hegel, *Phenomenologie des Geistes*; *Encyclopædie der Philosophischen Wissenschaften*. For some of the more recent views attributed to Schelling, see Stahl's *Philosophie des Rechts nach geschichtlicher Ansicht*, *&c. &c.*)

The Hegelian philosophy, as a whole, has been recently brought before English readers in Mr. Stirling's *Secret of Hegel*.

Scheme (Gr. *σχῆμα*). A plan or representation of any geometrical or astronomical figure; a diagram.

Schererite. [Scheererite.]

Scherif (Arab. *lord* or *master*). A title given in the East, by prescriptive usage, to those who descend from Mohammed through his son-in-law and daughter, Ali and Fatima. They are also called Emir and Seid, and have the privilege of wearing the green turban. [Emir.] The chiefs of Mecca and of Medina, who are always supposed to belong to this sacred family, are styled the scherifs of those cities.

Scheroma (Gr. *σκηρός*, another form of *ξηρός*, *dry*). A dryness of the eye, arising from a deficiency in the secretion of the lachrymal glands.

Schiah. [Sunniah.]

Schiller Spar. A hydrated silicate of magnesia, in which a large proportion of the magnesia is replaced by the protoxides of iron and manganese, and by lime. It occurs granular and massive, of an olive-green or pinchbeck-brown colour and with a shining semi-metallic lustre, at Baste in the Harz, in compact Schillerstein, and in Euphotide.

Schinus (Gr. *σχῖνος*, *the mastic-tree*). A genus of *Anacardiaceæ*, consisting of trees and shrubs, natives of tropical America, &c., having unequally pinnate leaves, which in some of the species are so filled with a resinous fluid, that the least degree of unusual repletion of the tissue causes it to be discharged. Some of them fill the air with fragrance after rain; and *S. Molle* and some others expel their resin with such violence when immersed in water as to have the appearance of spontaneous motion, in consequence of the recoil. *S. Areira* is said to cause swellings in those who sleep under its shade. The fresh juicy bark of this shrub is used in Brazil for rubbing newly-made ropes, which it covers with a bright dark-brown varnish. The juice of this plant is used in diseases of the eyes. The root of *S. Molle* is used medicinally in Peru, while the resin that exudes from the tree is employed to astringe the gums. The specific name *Mollé* or *Mulli* is an adaptation of the Peruvian name for the shrub.

Schirrus (Gr. *σκιρρός*, or *σκιρός*, *dry*, *hard*). An induration of a gland, forming an indolent tumour, not readily suppurating, and at first unattended by discoloration of the skin.

Schism (Gr. *σχίσμα*, from *σχίζω*, *I cleave*). Separation from an organised society. The term is generally applied by the members of ecclesiastical or theological bodies to persons separating from their own communion. Thus, the chief schisms enumerated by Roman Catholic authorities are those of the Novatians, the Donatists, the Luciferians, the Greek church, and the Protestants. The great schism of the West in the fourteenth century holds also an important place in the history of the Papacy. [Antipope.]

Schisma (Gr. *σχίσμα*). In Music, an interval equal to half a comma; hence eighteen of them are required to make a complete tone.

Schist (Gr. *σχιστός*, *cloven*). Schists are fissile rocks greatly metamorphosed and generally having imperfect cleavage. Their basis is more silicious than argillaceous, and if the salts of alumina are present, they exist, not as clay, but as new combinations. Thus we have micaceous schists, chloritic schists, garnet schists, &c. Schists occur geologically with metamorphic rocks, overlying or interstratified with gneiss and even granite. They differ from slates in being imperfectly fissile, and from shales in being perfectly metamorphosed. They are very abundant in mountainous countries, sometimes forming the entire mountain mass, but more frequently flanking a granite nucleus. They often contain metalliferous veins; but rarely have any other economic value, not being readily dressed to a smooth surface, and not answering the purpose of either stone or slate for building. As rough stones, they are not uncommonly made use of for walling. [Chlorite Schist; Gneiss; Mica Slate; Slate.]

Schizandraceæ (Schizandra, one of the genera). A small order of Diclinous Exogens, referred by Lindley to the Menispermal alliance; in which it is known by its hypogynous stamens, pendulous seeds, and minute embryo enclosed in copious solid albumen. The order is by some botanists regarded as a tribe of *Magnoliaceæ*, distinguished from true *Magnoliæ* chiefly by their climbing habit, want of stipules, and unisexual flowers. They extend over tropical and Eastern Asia and North America.

Schizopods (Gr. *σχιζόπους*, from *σχίζω*, *I divide*, and *πούς*, *a foot*). The tribe of long-tailed Decapod Crustaceans, including those which have the legs slender and filamentous, accompanied by an external articulated branch as long as the limbs, which thus appear doubled in number; fitted for swimming, and not cheliferous, the eggs being carried beneath them, and not under the tail. The opossum shrimps (*Mysis*) are examples of this tribe.

Schmidelia (after C. C. Schmidel, a professor of botany at Erlangen). A genus of *Sapindaceæ* distributed through the tropics of

both hemispheres, consisting of trees or shrubs. The fruits of *S. africana* form one of the many remedies employed in Abyssinia against the tapeworm. The dried fruits are pounded and mixed with flour, and then made into cakes. The sweet pulpy part of the fruit of *S. edulis* is eaten in Brazil, where the fruits are called Fruta de Paraô; but the seeds of most of the genus possess unwholesome properties, and those of *S. Cobbe*, a Cingalese species, are reputed to be poisonous.

Scholarship. The common appellation, in the two English universities, of foundations in colleges, inferior to fellowships, but superior to 'exhibitions,' for the maintenance of scholars under certain regulations. Also in the universities themselves, as rewards of proficiency. Since the issue of the royal commission for enquiring into the state of the universities, the scholarships in the colleges of Oxford have been rendered entirely free from preferences in respect of kindred to the founders; there are also very few subject to preferences in respect of place of birth. The great majority, therefore, are open to all candidates below a fixed age, which in some colleges is nineteen, in others twenty. It should be mentioned, that in some colleges, some of the scholarships are set apart for candidates from certain schools. The elections to scholarships are decided by an examination of the candidates; and the subjects of examination are, in the majority of cases, the Latin and Greek languages. Some scholarships are given for attainments in mathematics, and in physical science. [BURSARS.]

Scholastic Philosophy. That method of philosophising which arose in the schools and universities of what are commonly called the dark ages. The father of the schoolmen was John Scotus Erigena, a native of Ireland, who lived in the ninth century. He first introduced among his contemporaries (it is not known from what source) the philosophy of Aristotle, which he combined with the doctrine of the new Platonists, and out of the combination constructed a complete system of Pantheism. These speculations were at first regarded by the church with an evil eye; nor was it before the expiration of the following century that they were applied to the purpose of explaining and supporting the leading facts of Christianity. It was probably the necessity which was felt of combating heretics with their own weapons, that caused the universal adoption of the Aristotelian philosophy by the great religious authorities of the day. It is at any rate certain, that the subtlety and ingenuity of the early schoolmen were confined to the task of constructing a scientific basis for the doctrines of the church out of the materials afforded by that system. The scholastic philosophy may be said to have expired with the conclusion of the fourteenth century, at least as to its influence on the leading minds of the age. Four distinct periods have been observed in the course of its developement; the first beginning with its earliest commencement, and including the names of Berengarius, Lanfranc, Anselm, and Hildebert. The second era commences with the rise of the sect of Nominalists, the founder of whom was Johannes Roscellinus, and their most distinguished member the celebrated Peter Abelard. The third period is marked by the introduction into Europe of the writings of the Arabian philosophers, and the translation into Latin of their versions of Aristotle's writings, with the complete ascendency of REALISM, and the now undisputed supremacy of Aristotle. The greatest names in this period, which embraces nearly all the thirteenth century, are those of Albertus Magnus, Thomas Aquinas, and Duns Scotus, with the respective followers of the two latter, the Thomists and Scotists. The glaring realism of Scotus roused the independent spirit of an Englishman, William of Ockham, to a closer investigation of the internal conditions of thought, and in him led to what may be considered a transition state between the formation of the old schoolmen and the tendency towards nature and experience which distinguishes modern speculations. The acuteness of this man restored the victory to the Nominalists. His nominalism, however, differed from that of Roscellinus and Abelard in the admission that 'universals' have a foundation of reality in the subjective conditions of the intellect, though not an outward nature; whereas, according to the former, a general term was a name only—a *flatus vocis*.

The scholastic theology, to adopt the definition of Hallam (*Introduction to the Literature of Europe in the Fifteenth, Sixteenth, and Seventeenth Centuries*), was, 'in its general principle, an alliance between faith and reason; an endeavour to arrange the orthodox system of the church, such as authority had made it, according to the rules and methods of the Aristotelian dialectics, and sometimes upon premisses supplied by metaphysical reasoning.' The scholastic philosophy, according to the same author, seems chiefly to be distinguished from this theology by a larger infusion of metaphysical reasoning, or by its occasional enquiries into subjects not immediately related to revealed articles of faith. There can be no doubt that the sudden rise and expansion of the scholastic method was favourable to the growth of mental vigour and illumination; since it substituted rigid reasoning, although on premisses for the most part fanciful, for that mere acquiescence in authority which had distinguished the theology and the scanty remnant of philosophy which subsisted in the ages immediately preceding. France, Germany, England, and at one period Spain, were the principal seats of the scholastic controversies: in Italy they had less influence. Our own island has indeed the honour of having produced an unusual proportion of the chief names in this department of literature. The best known among these are Duns Scotus, before mentioned; and William of Ockham, one of the last of the distinguished schoolmen

who flourished in the fourteenth century. In the fourteenth century, the dialectic method of the schools was applied by some learned legists to the science of jurisprudence. Bartolus and Baldus have the highest reputation among the scholastic jurists. (Milman, *Latin Christianity*, book xiv. ch. iii.; Tennemann, *Geschichte der Philosophie*; Hampden, *Bampton Lectures*, 1833.)

Scholiasts (Gr. σχολιαστής). The name given to the old grammarians, or critics, who used to write annotations, called *scholia* (the fruits of σχολή, or leisure), on the margin of the manuscripts of the classical authors of antiquity.

Scholium (Gr. σχόλιον). In Geometry, an explanatory observation, or excursive remark, on the nature and application of a train of reasoning.

Schools of Design. Government art schools, first established in 1837 at Somerset House, in consequence of the recommendation of a Committee of the House of Commons on 'Arts and their connection with Manufactures,' made in 1836. The object was to give a suitable education in art to designers employed or wishing to be employed in our factories in those departments of manufacture in which beauty of design constituted an essential element. By degrees branch schools were established in the various provincial towns dependent on manufactures, in connection with the head school at Somerset House. The principal branches were at Manchester, Sheffield, Nottingham, Birmingham, Newcastle, Glasgow, and Belfast. Eventually the branches became very numerous. Differences of opinion arose as to whether the education should be special or general. The common-sense principle has finally prevailed: the art education given is theoretical and general, so that the students, instead of being confined to any narrow specialties of education, are so taught as to be able to adapt themselves generally to such specialties as may be required from them in the various towns in which they settle and find employment. The principles of art are the same in all manufactures; it is only the application that is special, and this can be best learnt in the factory. The thoroughly educated art student can apply himself to any art manufacture, though some may limit their labours more especially to modelling in the round, while others will devote themselves to designing in the flat.

In 1852, the head school was removed from Somerset House to Marlborough House, where it changed its name into a Department, that of 'Practical Art.' This very vague title, however, was soon dropped, in favour of that of 'The Department of Science and Art;' and, from being under the control of the 'Board of Trade,' it was transferred to the direction of the 'Committee of Council on Education,' under which it now is, in its own extensive premises at South Kensington, whither it was removed from Marlborough House in 1857.

The Central School of Art at South Kensington has gradually become subordinate, as regards the public, to the Art Museum established there, which is gradually assuming gigantic proportions. At this central school, however, a very good art education is to be had, not only for designers for manufactures, but for artists and architects also. The entire fees amount to 10*l.* per annum. A good art library is attached to the school and museum. See the various *Parliamentary Reports*, and other official papers, from the year 1836 to the present time.

Schools, Free and Endowed. Schools in which elementary education in the classical languages is afforded, according to the intentions of the founder. A few among these have acquired, in popular phraseology, the designation of public schools. Nearly 500 are described by Mr. Carlisle in his work on these institutions.

The common notion, that a free school means a place of gratuitous education, cannot be maintained. Dr. Kennedy has shown (*Schola Libera*, 1862) that schools thus entitled are such as are free from the authority or supervision of colleges and chapters. At the Reformation, Edward VI. founded many such free schools, in order to counteract the influences of the religious bodies under which the education of the country, and particularly of those who were destined for service in the church, almost wholly lay. Thus Eton, Winchester, and Westminster, are still collegiate schools. At Canterbury, Ely, and elsewhere there are cathedral schools; and in these schools the education is partly or wholly gratuitous: but whether such be statutably the case with the free schools or not, the term *libera* certainly has no such meaning either in classical or mediæval Latin. The free schools, established by Edward VI. and by private founders after him, as by Lyon at Harrow, Sherriffe at Rugby, &c., are generally grammar schools, some of which have risen in general estimation into the rank of what are called PUBLIC SCHOOLS.

Schools, Infant. These schools, for the education of children up to the age of five or six years, are said to owe their origin, as a public institution, to Mr. Owen of New Lanark. In the report of the Education Commission of 1863 they are divided into private or dame schools, and public infant schools, 'which frequently form a department of an ordinary day school.' In fact, it will be found that in the stage which popular education has now reached, infant classes, in Sunday and day schools, have, to a certain extent, superseded special schools for infants. In the best infant schools (say the commissioners) 'much is done, and even much is taught.' 'The real education of the children is carried on for the most part in the direct intercourse with the teacher: the children seated in the gallery, and the teacher standing before them, and constantly "performing," as it were, with such varieties of position, attitude, tone, gesture, method, and bearing, as shall best warm their minds to the

reception of the new truths that are to be conveyed to them.' In 1854, Mr. Horace Mann (*Census of Education*) estimated the total number of scholars in Great Britain under the age of six at 400,000; which, at the rate of increase observed in scholars generally, would now reach 600,000 or 700,000.

Schools, National. After public attention had been drawn to the advantages of Dr. Bell's system of mutual instruction in schools, chiefly through the activity of Mr. Lancaster, two societies were formed in England for carrying it into general operation. The British and Foreign School Society was founded by Dissenters in 1805; the National Society, by members of the Establishment, a few years later. The instruction of the former, in religion, is confined to those points in which all are agreed; that of the latter is founded on the liturgy and catechism of the established church. The schools of these two societies are now extensively spread over the face of the kingdom. The education given by them is nearly gratuitous, but certain small payments are in some cases exacted. Mr. Hill, in his work on the state of education in England, estimated the children attending schools of the former union at 60,000 or 80,000, and those of the National schools at about 170,000. Reading, writing, and arithmetic, with religious knowledge according to the principles of the respective institutions, form the amount of education generally given; but in some schools geography, and even the elements of geometry, are taught; and attempts have been made to add instruction in various branches of manual industry. Each society has a model school and establishment for training teachers. That of the British and Foreign is in the Borough Road: the principal one of the National in the Sanctuary, Westminster; but it has others in different places.

Schools, Normal. Schools for the education of persons intended to become schoolmasters, teachers, or professors in any line. Normal schools form a regular part of the establishments for education in many Continental states, especially in Germany. The normal school of Paris was suppressed in 1821, but revived a few years afterwards. In England there are many establishments, known as Training Colleges, for the purpose of educating masters for Primary Schools.

Schools, Primary. A phrase popularly applied to all schools devoted to the elementary education of the poorer classes: of which Sunday schools and day schools (National, British and Foreign, &c.) are classes. Mr. Mann (*Educational Census of* 1854) excludes mere infant schools from this category. In Great Britain, the number of primary schools, inspected by government officers, had increased from 4,237 in 1856 to 8,438 in 1865; the average number of children in attendance, from 571,000 to 1,300,000. The public expenditure for education grants from 1839 to 1862 amounted in round numbers to 6,700,000*l.*: of which about 4,000,000*l.* had been expended on schools in connection with the Church of England; 600,000*l.* in schools of the British and Foreign Society; 400,000*l.* of the Church of Scotland; 300,000*l.* of the Free Church of Scotland; 300,000*l.* Wesleyan; 200,000*l.* Roman Catholic. The expenditure in 1865 was 636,810*l.*

Schools, Public. This is a name of not quite definite application, by which a certain number of schools are designated, conferring a classical education, having on the average a large number of boys, and frequented by the children of persons of rank and wealth. The principal are: 1. The three colleges, two of royal and one of private foundation—Eton, Winchester, and Westminster. 2. Some or all of the great metropolitan endowed schools, such as Charter House, St. Paul's, Merchant Tailors'. Accordingly, these six foundations, together with those of Harrow, Rugby, and Shrewsbury, were specified as public schools in the commission directed in 1861 to 'enquire into their administration and management, and the system and course of studies respectively pursued therein,' &c.; the report of which body, with its evidence, furnishes now by far the most valuable guide to a knowledge of the several subjects.

Of these schools, the majority have a considerable *foundation*, i.e. a certain number of boys are educated there on what may be termed the collegiate principle, living together, and with their expenses to a great extent defrayed by the foundation. But at those of private establishment the foundationers are mere day scholars. At Eton, there were, in 1861, 61 foundationers (or *collegians*) and 722 non-foundationers (*oppidans*); at Winchester, 69 and 128 respectively; at Westminster, 40 and 96.

The great purpose of these schools at the present day is, therefore, the education of the sons of members of the higher classes of society, not on the foundations. And this is notoriously expensive. Generally speaking, it may be said that boys remain at these schools from the age of twelve or thirteen to eighteen or nineteen. The ordinary expense of a boy at Eton is stated by the commissioners at 144*l.* per annum, besides *extras* amounting in most cases to 20*l.* or 30*l.* more, 'exclusive of clothes, pocket money, and other pocket expenses.' The expense of Harrow is probably equal, that of the others somewhat less.

The governing body (in the royal foundations) is 'the college,' consisting of a head and fellows or canons; in most of the others, in a body of 'governors,' usually self-elected and incorporated. These appoint, and can dismiss, the head master, who usually appoints the assistant or under masters.

The course of study pursued in these great schools is still mainly classical. Mathematics, modern languages, and other branches of knowledge, have been partially introduced, and under circumstances so varying as to render a summary impossible. The extension

of the *course* is very strongly recommended by the commissioners.

The discipline of these schools varies greatly, under the administration of successive masters. With regard to one point in it which has attracted much attention, *fagging*, the commissioners report that some menial offices, too commonly assigned to *fags*, ought in their opinion to be allotted to servants; but, on the whole, and with allowance for the exception produced by occasional tyranny and mismanagement, they think that it 'is not degrading to the juniors, and has no injurious effect upon the character of the seniors.'

The public schools had in former times a closer connection with the universities than they now have, or are likely to retain. Eton (i.e. the college) monopolised the foundation of King's College, Cambridge; Winchester, that of New College, Oxford; other schools had numerous scholarships and fellowships appropriated to their pupils. But the changes of late years in the universities themselves have materially affected these privileges.

The royal commission, 1862, for enquiring into the conduct of the public schools extends to those above mentioned, with the exception of Christ's Hospital.

Schools, Scottish Parochial. In the reign of James IV. (1494), the Scottish legislature enacted that all barons and substantial freeholders should send their children to school from the age of six to nine years, and afterwards to the academical institutions. But it was not until 1615 that the foundations of the present system were laid by an Act *empowering* the bishops, together with a majority of the landlords, or *heritors*, to establish schools in every parish. In 1696, by another statute, the establishment of such schools was *directed*. The appointment of the schoolmaster was vested in the heritors and minister; the burden of the expense of erecting the school and a dwelling-house for the master, and paying to the latter a salary of not less than 5*l*. 11*s*. 1*d*. nor more than 11*l*. 2*s*. 2*d*. per annum, being supported by the former. The general supervision of the schools was intrusted to the presbyteries in which they were situated. Besides the salary (which has been raised to a maximum of 34*l*. 4*s*. 4½*d*., and a minimum of 25*l*. 13*s*. 3⅜*d*.), the master is supported by trifling fees from the scholars. Reading, writing, and arithmetic, some of the branches of practical mathematics in ordinary use, and even a slight amount of classical learning, have been usually taught in these parish schools. Such is a short outline of the system, of the results of which, in the general education and morality of the poorer classes, Scotland has been so justly proud.

Schools, Sunday. These schools were first set on foot by Mr. Robert Raikes of Gloucester. According to Mr. Hill, in his work on national education, the number of children frequenting Sunday schools varied, when he wrote, from 800,000 to 900,000. The average length of a Sunday-school education he estimates at four years; the education given is almost uniformly confined to reading alone; but many Sunday schools appear to have evening schools connected with them, open two or three times a week, in which writing and arithmetic are taught.

Schooner. A small sharp-built vessel, with two masts of considerable length and rake, with small top-masts, and fore and aft sails. A square-rigged schooner carries square topsail and top-gallant sails; but a fore-and-aft schooner has fore-and-aft sails on both masts, with occasionally a square topsail on the fore-mast. Schooners have sometimes, though rarely, three masts. It is one of the swiftest rigs.

Schorl (Swed. skorl, *brittle*). The name given to black opaque varieties of Tourmaline. It is a silicate of various bases, chiefly alumina, soda, lime, magnesia, and iron. It occurs in vitreous prismatic crystals; it is brittle and has much lustre, and becomes electric by heat and friction. It is found in Cornwall, at Boscawen Cliffs, Botallack Mine, St. Michael's Mount, and generally on the borders of the granite of that county; also in the granite of Chudleigh in Devonshire and off Portsoy in Banffshire; Stillorgen, co. Dublin, &c.

Schreibersite. A mineral of a steel-grey colour often found in meteoric stones. It is chiefly composed of phosphorus, nickel, and iron; and was named after V. Schreibers, of Vienna.

Schrötterite. A hydrated silicate of alumina found at Dollinger Mountain, near Freienstein in Styria, in amorphous greenish or yellowish masses; also in Alabama at the falls of Little River, Cherokee county, in brownish translucent incrustations, which resemble gum arabic when broken. Named after J. S. Schrötter.

Schulzite. An antimonial sulphide of lead found in Spain, at Meredo in Gallicia, in nodules in Galena.

Schweinfurth Green. A compound of arsenious acid, acetic acid, and oxide of copper, in appearance much resembling Scheele's Green.

Sciadopitys (Gr. σκιάς, σκιάδος, *a canopy*, and πίτυς, *a pine-tree*). The Umbrella Pine, a genus of Coniferous trees peculiar to Japan, and recently introduced into our gardens. It has been cultivated from time immemorial by the Japanese around their temples. The trunk is erect, from 100 to 150 feet high, the habit pyramidal, the branches verticillate; the leaves are linear and sessile, from thirty to forty growing together at the end of the branches. It is a singular and valuable evergreen tree, of a highly ornamental character.

Sciænoids (Gr. σκίαινα). The name of a family of Acanthopterygian fishes, of which the genus *Sciæna* is the type. This family is nearly allied to the Percoids; but both the vomer and palatine bones are without teeth; the bones of the head are generally cavernous, and the muzzle more or less enlarged and obtuse.

Sciatic Artery. One of the large branches of the anterior trunk of the internal iliac artery is so called. It supplies the deep-seated muscles at the back of the hip.

Sciatic Nerve. The largest nervous cord in the body. It supplies nearly the whole of the integuments of the leg, the muscles of the back of the thigh, and those of the leg and foot.

Sciatic Stay (possibly a corruption of *Asiatic*). A rope passing between the main and fore tops and sustaining a pulley used in loading or unloading the hold of a ship. The pulley can move upon the sciatic stay.

Sciatica (Gr. ἰσχίον, *the socket of the thigh joint*). A rheumatic affection of the hip joint. [Rheumatism.]

Science (Lat. scientia). In its most comprehensive sense, this term is applied to the knowledge of many, methodically digested and arranged so as to become attainable by one. The knowledge of reasons and their conclusions constitutes *abstract*, that of causes and effects and of the laws of nature *natural* science. The term *science* is, however, more particularly used in contradistinction to *art* and *literature*. As distinguished from the former, a *science* is 'a body of truths, the common principles of which are supposed to be known and separated, so that the individual truths, even though some or all may be clear in themselves, have a guarantee that they could have been discovered and known, either with certainty or with such probability as the subject admits of, by other means than their own evidence.' [Art.] As distinguished from *literature*, science is applied to any branch of knowledge which is made the subject of investigation with a view to discover and apply first principles. [Literature.] The various sciences will be found under their particular heads.

For the distinction of deductive and inductive science, see Aristotelian Philosophy, Baconian Philosophy, Socratic Philosophy; and for the canons of inductive science, see Logic.

Scilla (Lat.; Gr. σκίλλα). A genus of ornamental bulbous plants of the order *Liliaceæ*, and related to hyacinths. They are chiefly interesting as flower-garden plants, some of them being amongst the most lovely of early spring flowers, and one or two being natives of our own country. The common name for the genus is Squill, but the medicinal squill, the most important plant of this affinity, is now referred to a distinct genus. [Urginea.]

Scillitin. The bitter principle of the Squill (the bulb of the *Urginea Scilla*, formerly *maritima*), to which its medical properties of an expectorant and diuretic are referable. It is a white substance, of a resinous appearance.

Scimetar. A curved sword, much used by Oriental nations, and frequently found in Europe in the latter half of the fifteenth century.

Scincoids. A family of Saurian reptiles, of which the genus *Scincus* is the type. They have short feet, a non-extensible tongue; the body and tail are covered with equal scales, like tiles; they have no impressed lateral line, and the toes are margined.

Scink. [Skink.]

Scintilla Juris (Lat. *a spark of law*). A possibility of legal seisin which has been supposed by some learned real property lawyers to exist in some cases in the grantee under a conveyance of hand, for the purpose of enabling springing or contingent uses to arise. [Use.] This highly technical doctrine was never generally admitted in theory, or much regarded in practice; it has, however, been recently thought proper to abolish it formally by stat. 23 & 24 Vict. c. 38, sec. 7.

Scintillation (Lat. scintillatio, from scintilla, *a spark*). In Astronomy, the term applied to the *twinkling* or tremulous motion of the light of the larger fixed stars; by which they appear as if the rays of light coming from them were not continuous, but produced by particles succeeding each other at intervals with a sort of vibratory movement. The planets, excepting when very near the horizon, have not this twinkling appearance; and they are thus readily distinguished from stars of the first magnitude. It arises from the extreme smallness of the apparent diameters of the fixed stars, and the unequal refracting power of our atmosphere at the different temperatures and pressures of the layers of air through which a star is seen. This unequal refraction causes the apparent displacement of the star to a small extent. The twinkling of the stars is therefore greatest when they are near the horizon, and when the air is disturbed by currents of unequal temperature. The stars near the zenith rarely twinkle, and when seen from the summit of a lofty mountain the phenomenon is also, for obvious reasons, greatly diminished.

Sciography (Gr. σκιαγραφία, from σκία, *a shadow*, and γράφω). In Painting, &c., the art of casting and delineating shadows with truth, and upon mathematical principles.

Sciolto (Ital.). In Music, a term which, applied to counterpoint, signifies that it is free and not constrained by general rules. When applied to notes, it signifies that they are not tied together 

Scion (Fr.). In Horticulture, the first young shoot produced during the year by a tree; or, more commonly, a part of a branch prepared for the purpose of being grafted upon some other tree.

Scioptic Ball or **Scioptric Ball** (Gr. σκία, *shadow*, and ὄπτομαι, *I see*). A name sometimes given to a mechanical contrivance, used in the *camera obscura*, for the purpose of giving motion to a lens in every direction.

Scire Facias (Lat.). In Law, a judicial writ, which lies in various cases, as for instance to call on a party to show cause to the court whence it issues why letters patent should not be repealed.

Scissel (Lat. scissilis, *that may be rent* or *cloven*). The clippings of various metals produced in several mechanical operations concerned in their manufacture. The slips or plates of metal out of which circular blanks have been cut for the purpose of coinage are called *scissel* at the Mint.

Scitamineæ (a name extracted from Lat. scitamenta, *dainties*). A group of monocotyledonous plants, formerly recognised, and including the Musas, the Gingers, and the Marantas of modern times. It is almost entirely tropical and includes many plants of considerable size, and all remarkable among monocotyledons for their leaves, which are often large and have pinnate or diverging veins, and for their unsymmetrical flowers, their perfect stamens being always reduced to five or fewer, whilst the perianth divisions are of the normal number, six. The whole group comprises three tribes or orders—*Musaceæ*, with more perfect anthers than one; *Zingiberaceæ*, with only one perfect two-celled anther; and *Marantaceæ*, with only one perfect one-celled anther—the other stamens (if present) being always converted into barren and mostly petal-like staminodia.

Sciurinea (Gr. σκίουρος, *a squirrel*). The Squirrel tribe. The name of a family of Rodents, of which the genus *Sciurus* is the type. They are distinguished by their very narrow lower incisors, and by their long and bushy tail. They have four toes before, and five behind. The thumb of the fore foot is sometimes marked by a tubercle. The molars are tuberculated.

Scleranthaceæ (Scleranthus, one of the genera). A small uninteresting order of perigynous Exogens belonging to the Ficoidal alliance of Lindley's arrangement. They are known by their apetalous flowers, and by their single solitary carpel, over which the tubular calyx becomes hardened. They are few in number, and occur on barren ground in Europe, Asia, and North America.

Sclerodermi (Gr. σκληρόδερμος, *hard-skinned*). A name given by Cuvier to a family of Plectognathic fishes, comprehending those which have the skin covered with hard scales.

Sclerogen (Gr. σκληρός, *hard*, and γεννάω, *I produce*). In Botany, the ligneous or bony matter deposited in the cells of plants.

Scleroskeleton (Gr. σκληρός, and σκελετόν, *a dried body*). Those bones which are developed in tendons, ligaments, and aponeuroses, e.g. the *tentorium* in the cat, the *temporal fascia* in the turtle, the *leaders of the leg-muscles* in the turkey, the *nuchal ligament* in the mole, and certain tendons of the abdominal muscles of the Kangaroo which, so ossified, are called the *marsupial bones*.

Sclerotica or **Sclerotic Membrane** (Gr. σκληρός, *hard*). The outer tunic of the eye is so called. In man it is opaque, and forms the posterior five-sixths of the globe of the eye. It is white externally, brown internally, and is much thicker behind than in front. In many birds, and some fossil reptiles, it developes a circular series of bony plates around the eyeball. [EYE.]

Scolex (Gr. σκώληξ, *a worm*). The first or primitive segment of a tapeworm (*Tænia*) is so called, which originates itself from a *Cysticercus*, and developes *proglottides*, who in their turn become free, and independent from the *parent* organism.

Scolezite or **Skolezite** (Gr. σκώληξ). A hydrated silicate of alumina and lime, which occurs in prismatic and acicular crystals, and also massive with a fibrous and radiating structure. It is colourless, snow-white, greyish, yellowish, and reddish, and transparent to translucent at the edges. It is found in Staffa, Iceland, Greenland, the Faroe Islands, the Tyrol, &c.

When heated before the blowpipe, it shrinks up with wormlike contortions before fusing; whence the name.

Scolopacidæ (Gr. σκόλοπαξ, *a woodcock*). The Snipe tribe. The name of a family of wading birds, of which the genus *Scolopax* is the type. The snipes proper have a straight beak, the nasal furrows extending to near its point, which is a little furrowed externally, so as to extend beyond the lower mandible. The point is soft and very sensible.

Scolopendra (Gr.). The generic name of the Centipedes.

Scolopendrium (Gr. σκολόπενδρα). The generic name of the Hart's-tongue, one of our common British species of ferns.

Scomberoids (Gr. σκόμβρος). The Mackerel tribe. The name of the family of fishes of which the genus *Scomber* is the type. They are characterised by having a smooth body covered with small scales, and a very powerful tail and caudal fin.

Sconce (Dan. skands; Ger. schanze, *a bastion*). An obsolete word, formerly applied to a small fort for the defence of a pass, river, or other place. (Scott, *Legend of Montrose*, ch. xi. &c.)

Scopa (Lat. perhaps *a thin branch*; but it is seldom found in the singular number: the plural, scopæ, is *a broom* or *besom*). In Mammalogy, a fasciculus of long flaccid hairs, which may grow from any limited part of the body or extremities.

Scoparin. The crystalline, neutral, diuretic principle of the *Sarothamnus scoparius* or Common Broom.

Scopipeds (Lat. scopæ, *a broom*, and pes, *a foot*). The name of a tribe of Melliferous insects, including those which have the tarsi of the posterior feet furnished with a brush of hairs.

Scops (Gr. σκώψ). The horned owl, of which more than one species is found in Great Britain.

Scoriæ (Lat.; Gr. σκωρία, *refuse*). Volcanic ashes of a reddish brown and black colour, the cinders and slags of a particular kind of lava. In appearance volcanic scoriæ greatly resemble the slags of an iron furnace, and

are in fact stony or imperfectly glassy products obtained under circumstances not very different in the great laboratory of nature.

Scorodite (Gr. σκόροδον, *garlic*, in allusion to its smell when heated). A hydrated arseniate of iron, formerly found in Cornwall on ferruginous quartz, and in pale bluish-green radiating groups, lining the interior of cavities.

Scorpio (Lat.). In Astronomy, the eighth sign of the zodiac, and one of the ancient zodiacal constellations. When this constellation rises, Orion sets; hence the mythological fable of the death of ORION, who perished by the sting of a scorpion. [CONSTELLATION.]

Scorpioid (Gr. σκορπιοειδής, *scorpion like*). In Botany, that form of inflorescence in which the main axis is curved in a circinate manner like the tail of a scorpion, as in the Forget-me-not.

Scorpion (Lat. scorpio; Gr. σκορπιός). A well-known Arachnidan Articulate, in which no spinnerets exist at the extremity of the body, their place being supplied by a venomous apparatus. They are common in the tropics, where they frequently attain a gigantic size. As in the case of most similar forms, the sting can be cured by the outward application of ammonia.

Scorza or **Skorza.** The common name in Transylvania for the granular Epidote, which occurs in the form of sand near Muska, on the banks of the river Aranyos.

Scorzonera (Span. escorza, *a serpent*). A genus of *Compositæ*, which includes a valuable esculent species. This plant, the *S. hispanica* of botanists, and the Scorzonera or Vipers' grass of gardeners, is a native of Spain, but is cultivated in this country for its roots, which are sold in the markets. They are of very easy cultivation, growing vigorously in good ground, and bearing our hardest winters without injury. The root is nearly the shape of a carrot, but smaller and dark-coloured, while internally it is pure white. The taste is sweet and agreeable, something like that of the roots of certain umbelliferous plants or the common hazel-nut. Its effects on the digestive organs are to increase the flow of gastric juice and bile, and as it acts as a deobstruent on the alimentary organs generally, it is slightly aperient. Its antibilious power is scarcely, if at all, inferior to that of dandelion. These good effects, however, cannot be insured unless the vegetable is properly cooked, as its medicinal quality may be quickly destroyed. It should be cut as little as possible, and washed instead of scraped, for the abundant milky juice, on which its salutary properties depend, escapes when it is bruised. After boiling for about twenty or twenty-five minutes or till it is quite soft (rather more salt being added to the water than usual in cooking vegetables), it is to be taken out and peeled, as the dark skin then comes off as readily as that of a boiled potato. When fresh from the garden, a quarter of an hour may be sufficient. It is of some importance to the invalid to know this, because after it has become quite soft all further boiling is injurious to its medicinal quality and soon destroys it; but when it has lain out of the ground for a long time and become hardened, it may require twice the time boiling, the rule then being to boil it till it is soft. It is usually eaten in the same way as asparagus, which is the preferable mode for the invalid. As it is one of the most agreeable of vegetables as regards flavour, it undoubtedly deserves to be much more cultivated.

Scot (Sax. sceat, *part* or *portion*, in the sense of contribution). This old word has passed into various ordinary expressions, such as 'scot-free,' &c., and at one time found its way into the Italian language (Dante, *Purgatorio*). In English Law, it is still retained in the phrase 'inhabitants paying scot and lot,' which has long been held to mean paying parochial rates, and constituted one of the old rights of voting in various boroughs existing before the Reform Act.

Scotch Bonnets. The Champignon, *Marasmius* (or *Agaricus*) *Oreades*, one of the Fungi which give rise to fairy rings.

Scotch Pebble. A name given to the Agates found in Scotland, where they occur abundantly, as irregularly shaped nodules, in the amygdaloid of Dunbar and the hill of Kinnoul near Perth.

Scotches (perhaps connected with A.-Sax. sceadan; Gr. σχίζη, *a cleft piece of wood*). Wedges of wood placed under a wheel to stop its rolling.

Scoter. A name of the black duck, or Black Diver (*Anas nigra*, Linn.), now the type of the subgenus *Oidemia*, Fleming.

Scotia (Gr.). In Architecture, the name of a hollow moulding, chiefly used between the tori in the bases of columns. It takes its name from the shadow formed by it, which seems to envelop it in darkness.

Scotists. An old scholastic sect, followers of Duns Scotus, 'the subtle doctor,' one of the leading champions of Realism in the thirteenth century. He held that the *universal* existed not *in posse* only, but *in actu*; not depending in anywise on the conditions of the understanding, but presented to it as an outward reality. In this respect his realism differs from that of his predecessor, Thomas Aquinas. [SCHOLASTIC PHILOSOPHY.]

Scotodinia (Gr. from σκότος, *darkness*, and δίνη, *a whirling*). Giddiness with imperfect vision. A symptom occasionally observed in dyspepsia, especially in that of gouty persons.

Scouring Drops. The essential oils of lemon and of bergamotte are sold under this name, for the purpose of removing grease stains from silk dresses. They are generally adulterated with oil of turpentine.

Screeds (etym. uncertain). In Architecture, wooden rules for running mouldings. Also the extreme guides on the margins of walls and ceilings for floating to, by the aid of the rules. They are always necessary for running a cornice when the ceiling is not floated.

Screen (Fr. écran). In Architecture, a partition usually wrought with rich tracery. Such partitions were commonly erected in churches as supports of the rood-loft [ROOD], and to rail off altars, chapels, and tombs from the rest of the building.

Screw (Dutch schroef, Ger. schraube). In Mechanics, one of the six mechanical powers, consisting of a spiral ridge or groove, winding round a cylinder, so as to cut every line on the surface parallel to the axis at the same angle. The screw may be formed either on the outside or inside of the cylinder; in the former case, it is called the *exterior* or *male* screw; in the latter, the *interior* or *female* screw. The action of the screw resembles that of the wedge, or inclined plane; but as the cylinder has always a handle attached to it, the screw is in reality a compound of the inclined plane and lever; and if the direction of the power be parallel to the base of the cylinder, and perpendicular to its radius, equilibrium is produced when the power is to the resistance or pressure as the interval between the adjacent threads is to the circumference described by the point to which the power is applied. Hence the mechanical advantage afforded by the screw is proportional jointly to the fineness of the threads and the length of the lever or handle. It is to be observed, however, that by diminishing the distance between the threads, we diminish also the strength of the screw; and hence there is obviously a limit to the increase of power. But the action is greatly increased by means of the contrivance called a *differential screw*, or, from the name of its inventor, *Hunter's screw*, which consists in the combination of two screws of unequal fineness of thread, one of which unwinds while the other winds, and the effective progression at each revolution is only equal to the difference of the pitches of the two screws, which may be made as small as we please, and consequently the screw may be made as powerful as we please, since the power is always corresponding to the slowness. In Hunter's screw we obtain the power due to a very fine pitch without its weakness.

The *endless screw* consists of a screw combined with a wheel and axle in such a manner that the threads of the screw work into the teeth fixed on the periphery of the wheel. Suppose the power applied to the handle of the screw, and the weight attached to the axle of the wheel, then there will be equilibrium when the power is to the weight as the distance between the threads multiplied by the radius of the axle is to the circumference described by the power multiplied by the radius of the wheel.

The *water screw*, or *screw of Archimedes*, is formed by winding a tube or channel round a cylinder in the form of a screw. If the machine, thus constructed, be placed obliquely, so as to make with the vertical an angle equal to that which the spiral makes with the lines parallel to the axis of the cylinder, there will be in each convolution of the spiral a part parallel to the horizon. If any body, then, be placed within the spiral at this part, it will remain at rest; and if the screw be turned the body will ascend, because the part of the screw behind it becomes more inclined than the part before it, and it is consequently urged forward. This simple but ingenious contrivance is usually employed for the purpose of raising water to a small height, but it may be employed to raise any substance that can pass within the tube.

The *micrometer screw* is a contrivance adapted to astronomical or optical instruments, for the purpose of measuring angles with great exactness. The very great space through which the lever of the screw passes in comparison of that which is described by the cylinder in the direction of its length, renders the screw of immense use in subdividing space into minute parts.

As a mechanical power, the screw has innumerable applications; but it is employed with most convenience in cases in which a very great pressure is required to be exerted within a small space, and without intermission. A common purpose to which the screw is applied is that of connecting pieces of wood or metal together either in the form of screw nails or in that of bolts and nuts. In both cases the friction of the thread of the screw is sufficient to prevent the screw from unwinding when forcibly tightened up, and the screw is of invaluable use in the arts for attaching objects firmly together. If there be much jar or vibration in the objects thus connected, the screws will be liable to work loose; and in the screws used to attach the floats of paddle-wheels to the arms, and in the various attachments of locomotives, the nuts are liable to shake loose. In some cases a second nut, called a *jam nut*, is introduced above the common nut to prevent unwinding, and this is usually done in the bolts of paddle wheels; but besides this, the thread should be slightly nicked with a chisel to prevent the nut from working back. In locomotives *split pins*, as they are termed, are introduced running through holes in the point of the bolts; and these pins, after being pushed through the holes provided for their reception, expand sideways, and cannot fall out, while their presence prevents the nuts from unscrewing without clipping them off.

Screw Jack. An instrument employed for lifting heavy weights and consisting essentially of a screw so disposed as to enable the pressure it exerts to be conveniently applied. A similar instrument, called a *dumb craft*, is sometimes used instead of a screw jack into which wheels and pinions are introduced which protrude a ram by means either of a rack or screw; and by the point of this ram the pressure is communicated.

Screw Pine. The common name for the species of *Pandanus*. [PANDANACEÆ.]

Screw Propeller. An instrument for the propulsion of vessels, consisting of two or more

twisted blades, like the vanes of a windmill, set on an axis running parallel with the keel, and revolving beneath the water at the stern. The screw propeller is driven by a steam engine situated within the vessel, and by its revolution in the water it carries the vessel forward, as a cork-screw is drawn forward when penetrating a cork, or a bolt when turned round in a stationary nut. The water in which the vessel floats forms the nut of the screw propeller; and thus when the propeller is turned round, the vessel is screwed on. To enable the water to act as the nut of the screw, the thread traced in the water requires to be very much deeper than if it were traced in metal or wood, and the pressing surface of the screw must be large, to prevent the thread from being stripped or broken by the reacting force. Accordingly, screw propellers are made with a small central body and deep thread; they are also made as large in diameter as possible, reaching, usually, from the keel to near the surface of the water. In the length of the screw only a very short piece, usually about one sixth of a convolution, is employed.

History of the Screw Propeller.—The screw propeller is probably as old as the windmill; and a windmill of the construction now usually employed is represented in the 77th proposition of Hero's *Spiritalia*, a work written 130 years before the Christian era. In China screw propellers are said to have been employed from a very early date as an arrangement for sculling vessels; and in fact a screw is a continuous sculling machine, in which the necessity of reciprocating motion is superseded by giving a complete revolution to the propelling blade. Captain Basil Hall, in his account of his voyage to Loo Choo, states that the Coreans scull their ships instead of rowing them; and, from what he saw of the operation, he is inclined to give the preference to that mode of propulsion. The galleys of the Greeks and Romans were also propelled by an action of the oars more nearly resembling sculling than rowing, as was first pointed out by Robert Hooke in 1684; and Hooke also showed that this mode of action would be exceedingly efficient. In a work entitled *Philosophical Collections*, printed for Richard Chiswell, printer to the Royal Society, 1681, there is a paper by Hooke on Horizontal Windmills, containing various suggestions of great originality and importance. Hooke says that he does not consider horizontal windmills to be as efficient as vertical windmills: but if they are in any case employed, it will be advisable, he says, to make them on a certain construction, of which he gives a representation, and which is almost identical in its main features with the most improved species of feathering paddle wheel now employed in steam ships. Hooke adds, that wheels of this kind may be set to work advantageously as water wheels in a river where no dam can be made, as may also the common vertical windmill with twisted arms. In this cursory suggestion we have the germ both of the screw propeller and the feathering paddle wheel. Robertson Buchanian admits having taken the idea of his feathering wheel from the mechanism of orreries which was invented by Hooke; and the same considerations which make the screw and feathering wheel eligible instruments when driven by the water equally hold when the water is driven by them.

On October 14, 1683, Hooke showed to the Royal Society an instrument which he had invented for measuring the velocity of the wind. It consisted of four vanes, like the vanes of a windmill, set upon an axis, the vanes being so constructed that they could be set at any angle that was desired. On November 28, in the same year, Hooke showed to the Royal Society an instrument which he had shown to some of the members twenty years before, for measuring the way of a ship through the water. The prime mover of this instrument was a screw turned by the water, and the instrument not merely took cognisance of the progress of the vessel through the water, but also of the lee way. The plan of making gearing in steps, as is now usually done in such screw vessels as make use of gearing, is also an invention of Hooke's. Wheels made upon this principle are divided in the direction of their breadth into a number of parallel wheels which are set a little in advance of one another, so that the teeth of each do not come in the same line. The benefit of this practice is that the teeth, though necessarily very thick to give adequate strength, work as smoothly as if they were thin and small, or as if the space between the teeth were only a fractional part of its actual amount.

In the *Recueil de Machines approuvées par l'Académie, depuis* 1727 *jusqu'au* 1731, there is a machine described, which was invented by M. du Quet, for dragging up barges against a current in a river by the aid of a screw driven by the water; and by the screw thus driven a rope, dragging the barges, is to be wound up. This screw, which is a helical blade wound upon an axis, is only partially immerged in the water, and it would be a much less effectual instrument than the screw of a windmill form previously recommended by Hooke. In Bouguer's *Traité du Navire*, published in Paris in 1746, an arrangement of revolving oars, resembling the vanes of a windmill, is mentioned as having been proposed for the propulsion of vessels; but this expedient, it is stated, had not been found to possess sufficient force. In 1752, Daniel Bernoulli obtained the prize offered by the French Academy of Sciences for the best project for impelling vessels without the aid of the wind. Bernoulli's apparatus consisted of an iron axle 14 feet long and two inches thick, set upon each side of the vessel beneath the water. Each axle was to carry eight wheels, six feet diameter, set at equal distances from one another, and each wheel was to have eight arms or spokes, to the extremity of each of which a sheet-iron plane 16 inches square, and inclined so as to form an

angle of 60° with the axle or keel of the vessel, was to be affixed. Bernoulli's plan appears to have been contrived to meet Bouguer's objection, and it would probably answer for towing, but the revolution of such a large number of wheels in the water would in all cases of considerable speed occasion a serious loss of power from friction and other analogous causes.

In Emerson's *Principles of Mechanics*, published in 1754, we have an explanation of the mode of constructing screws with an expanding or increasing pitch. Emerson describes an arrangement of screw set vertically in a well or stationary cylinder, as an instrument for rendering available a fall of water in giving motion to mills. The water is admitted at the top of the cylinder and escapes at its base, and in its descent it turns round the screw by which the cylinder is filled up. Emerson explains, that at the top of the cylinder the blade of the screw must have very little inclination with the axis, but at the bottom of the cylinder the blade of the screw must have a considerable inclination with the axis. Blades set in a conical pit or vessel, and driven round by the gravity of water, have long been in use in France, under the name of Danaïdes, or *roues à poires*; and in some cases the blades were merely plane surfaces suitably inclined, while in other cases they were spiral or screw-formed. Instruments of this kind are described by Belidor in his *Architecture Hydraulique*.

In 1768, a work on the Archimedean screw was published at Paris by M. Paucton; and it is suggested that a ptérophore, composed of the circumvolution of the thread of a screw round a cylinder, should be placed on each side of a vessel to propel her through the water, or one only may be used at the fore part. These screws, it is stated, may be either wholly or partially immersed. In 1776, a submarine vessel was invented by D. Bushnell, an American, which was to be raised upward or sunk downward in the water by means of an inclined blade or oar affixed to the top and operating in the manner of a screw, and forced forward or backward in the water by another similar blade affixed to the bow. This vessel was to carry a powder magazine, which was to be screwed to the bottom of an enemy's ship to blow her up. It was the original of Fulton's torpedo.

In 1784, Joseph Bramah, of London, engineer, obtained a patent for propelling vessels by means of a wheel with inclined fans or wings, similar to the fly of a smoke-jack or the vertical sails of a windmill. This wheel was to be fixed to an axis passing out at the stern of the vessel, and was to revolve beneath the water with a stuffing box or proper packing surrounding the shaft, where it pierces the vessel, to prevent the water from entering. In 1794, William Lyttleton, a merchant of London, obtained a patent for an instrument which he called an 'aquatic propeller,' and which consisted of a single convolution of a three threaded screw. The thread of a screw is the projecting part of it, and a screw may have one, two, three, or any other number of threads. A string wound round a cylinder represents the thread of a screw; and if one string only be wound round it, the screw will be a screw of one thread; if two strings be wound round it, so as equally to divide the space, the screw will be a screw of two threads; and so of any number. If, instead of a string, a thin ribbon of iron be wound edgeways round the cylinder, and be soldered thereto, then a slice cut off the end of this screw will have two projecting arms or portions of this ribbon, if the screw be one of two threads; three projecting arms, if of three threads; and so of any other number. In any screw propeller, therefore, the number of threads is the same as the number of arms. The pitch of the screw is the distance from one thread of the screw to the next thread measured on the axis, supposing the screw to be continued through a whole convolution. A spiral stair is virtually a screw; and the pitch is the vertical distance from any one step of the stair to the step immediately overhead.

In 1799, Edward Shorter, of London, mechanic, obtained a patent for propelling vessels, and among the expedients which he employed is one termed a 'perpetual sculling machine,' consisting of a screw immerged in the water at the stern of the vessel. The shaft, which gives motion to the screw, passes through the stern of the vessel above the level of the water, and is armed at its extremity with one of Hooke's universal joints, from whence a pole extends obliquely into the water with the screw attached to its extremity. The end of the pole is prevented from sinking too deeply in the water by a buoy which supports it at the proper elevation, and guy ropes are applied, by means of which the pole and screw may be moved to the one side or the other, so that the vessel may be steered, or assisted in her steerage, thereby. Between 1800 and 1836 various arrangements of screw propellers were proposed by Dallery, Stevens, O'Reilly, James, Trevithick, Boswell, Millington, Scott, Whytock, Delisle, Bourdon, Dollman, Perkins, Brown, Tredgold, Maceroni, Cummerow, Smith, Church, Copley, Ovinel, Peltier, Salichon, Poole, Woodcroft, Sauvage, Emerson, Burke, Theal, Smith, and Fitzpatrick. The forms of these screws are very various, but in most cases they consist of helical blades, like the vanes of a windmill, revolving beneath the water at the stern, or of a helical feather coiled round an axis, in the manner of an Archimedean screw. In some cases the pitch of the screw is intended to be uniform, and in other cases increasing, the uniform pitch being a straight line wound upon a cylinder, and the increasing pitch being a curved line wound upon a cylinder, or a straight line wound upon a cone or spire. Bourdon, in 1824, formed his screw with an increasing pitch, and placed it in the dead wood of the vessel. Tredgold, in his work upon the Steam Engine, published in 1827, recommended that screws should be made with an increasing pitch. Peltier, in 1830, proposed to make his

screw with an increasing pitch, and Woodcroft proposed the same thing in 1832. Marestier, in 1824, in a work published by direction of the French government, giving an account of steam navigation in America, described various arrangements of screw propellers which had been tried in that country, but none of those expedients had come into practical operation. Lyttleton in 1794, Shorter in 1802, Stevens in 1804, Bourdon in 1824, and several others at different times, had practically tried the effect of propelling vessels by means of a screw. But these experiments led to no useful result, and in 1836 there was no vessel propelled by a screw in existence. In that year patents for propelling vessels by a screw were taken out by F. P. Smith and Captain John Ericsson; and to these two persons the successful introduction of the screw as a propeller must be attributed. Ericsson, not meeting in this country with the encouragement that he expected, went to America, where he soon after constructed the war steamer Princeton, and in 1862 he designed the Monitor class of screw turret vessels. Smith, as soon as his early trials had demonstrated the efficacy of the screw as a propeller, built the Archimedes, and soon afterwards his propeller was applied to the war steamer Rattler. It has subsequently been applied to most of the sea going steamers, whether constructed for purposes of war or of commerce in this and other countries, and is now the species of propeller in general use, although paddles are still used for river vessels and also for the conveyance of certain mails which require to be carried in all weathers at a high rate of speed.

It would swell these remarks beyond the limits to which they must be restricted, to attempt any enumeration of the various modifications in the form of the screw, and in the mode of its application, which have been made or proposed since its practical introduction as an available propeller. In this country vessels are, for the most part, fitted with screws of a uniform pitch formed with either two or three arms, but sometimes with four arms. Griffith's screw with shovel-formed blades and a central ball is much used in the navy, where a form of screw with four blades, of which the leading half of each blade has a less pitch than the following half, has also been in some cases employed; but has been discarded. Mangin's screw, which consists substantially of two double-bladed screws with very narrow blades set immediately behind one another on the screw shaft, has also been employed in some cases with good results, the space between the screws allowing the water to pass; and as the column of water in which the screw revolves is less put into rotation, there is less shake at the stern.

In Smith's earlier experiments upon the screw propeller he employed a single-threaded screw of two convolutions, such as that represented in fig. 1. During one of his trials, however, the screw having come in contact with some object in the water, about half of it was broken away, and the vessel was found in consequence to realise a higher speed than before. The Archimedes was originally fitted with a single-threaded screw of one convolution, such as that represented in fig. 2.; and it was with a screw

Fig. 1.

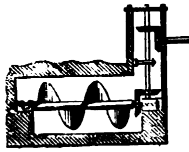

Fig. 2.

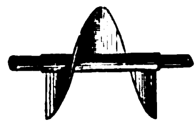

of this kind that the efficiency of the screw as a propeller was originally demonstrated. She was subsequently fitted with a double-threaded screw of half a convolution, which gave the same amount of propelling surface, and diminished the uneasy motion at the stern. This screw is represented in fig. 3. The Rattler was fitted with a screw of this kind, but its length was subsequently reduced to one-sixth of a convolution, which made its length just one-third of its original length, and the best results were obtained with this proportion. This amended screw of the Rattler is shown in perspective in fig. 4.

Fig. 3.

Fig. 4.

Ericsson, in his original form of propeller, employed two wheels armed with helical blades and revolving in opposite directions. The object of this arrangement was to neutralise any tendency which one wheel might have to turn the vessel from her appointed course. The second wheel however was soon discarded, as it was found that it was not required. Fig. 5 represents Ericsson's original arrangement of

Fig. 5.

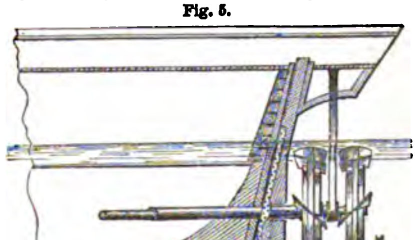

Fig. 6.

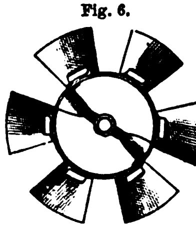

Fig. 7.

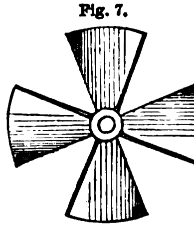
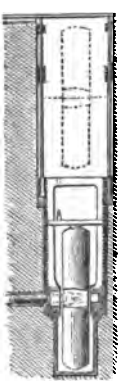


the screw propeller, and fig. 6 is the propeller of the Princeton, which was subsequently superseded by a four-bladed screw of the form shown in fig. 7.

Description of the mode of applying the Screw Propeller.—In the most approved method of introducing the screw propeller into a vessel, the screw is set in a hole or opening in the dead wood behind the stern post, and before the rudder post. It is sometimes hung upon a short shaft, which is carried by a metal frame with a rack on each side, and in these racks endless screws work, which, being put into revolution, raise the frame, lifting the propeller out of the water, so as to enable the screw to be repaired if required, or a new one to be introduced without putting the vessel into dock. Before, however, the frame can be raised, the shaft, which, passing through the ship, communicates with the engine, has to be pulled on end, so as to disengage it from the boss of the short shaft, which supports the screw. A vacant space is left between the end of the shaft which communicates with the engine, and the end of the shaft which communicates with the screw, so as to enable the shaft communicating with the screw to be drawn on end without disturbing the other shaft; and a short pipe fixed to the one shaft, but sliding on the other, is so applied that, notwithstanding the end play, the force of torsion will be communicated from the one shaft to the other. Figs. 8 and 9 represent the screw propeller and the apparatus for raising it out of the water, as applied in H.M. steam frigate Ajax. By a reference to these figures, the configuration of the screw usually employed for the service of the navy, and the mode of raising it out of the water, will be readily understood. A catch represented as engaging the centre of the screw is put down only when the screw requires to be raised out of the water, and its use is to retain the blades in a vertical position during that operation.

Fig. 8.



This method, however, of constructing the screw connections so that the screw might be raised out of the water when the vessel was under sail alone, though at one time widely adopted in the navy, never found much favour in the merchant service, and latterly in the navy also it has been discarded. The method described of raising the screw was available only when the screw was formed with two blades, and in most cases it is found advisable to keep the screw in water at all times, but to let little steam into the engines when the wind is fair, thus economising the coal nearly as much as if the screw were to be disused altogether during those periods.

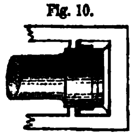
Fig. 9.

The screw shaft, at the point where it passes through the stern of the vessel, is kept tight by means of a stuffing box, consisting of a long pipe fitted tightly into the hull of the vessel. Through this pipe the screw shaft passes, and the space between the shaft and the pipe is kept tight by means of a plaited rope of soft hemp forced tightly into a recess provided for the purpose by means of screws. It is very desirable that the shaft should fit so accurately into this pipe as to be exempt from all side play, which, if it exists, will have the effect of communicating a disagreeable motion to the stern of the vessel. In wooden vessels the pipe should be made of brass; and it has been found advantageous to cover with brass that part of the shaft that revolves within the pipe, so as to obviate corrosion from the sea-water and also to enable strips of lignum vitæ to be introduced to constitute a bearing for the shaft. Wooden bearings or bushes are found to be better than metal ones in the case of all shafts or bearings working in water. But the metallic surface in contact with the wood should be brass and not iron when salt water is the lubricant, else the iron will be roughened by corrosion, and will then rasp the wood rapidly away. In all cases the extremity of the vessel in advance of the screw should be brought to as fine a line as possible, and the hole in the dead wood in which the screw revolves should be considerably larger than the screw itself. The screw in its revolution carries with it a coating of water, and if this coating be partially stripped off at every revolution from the too near proximity of the stern part of the vessel, a shock will be communicated at every revolution, from the impact of the water against the side of the dead wood, and a part of the engine power will be also dissipated without effect.

Modes of receiving the Thrust of the Screw.—As the screw by its revolution is forced forward in the water, carrying the vessel with it, the screw shaft, it is clear, must have to sustain a forward thrust, and it is this thrust, in fact, which propels the vessel. The severity of this forward thrust, combined with the velocity of rotation which the screw shaft must maintain, was the occasion, in the earlier screw vessels, of considerable inconvenience, in consequence of the friction produced; and several cases have occurred where the end of the shaft became white hot, and actually welded itself to the steel plate against which it pressed, although a stream of water was all the while running upon the surfaces in contact. Various expedients have since that time been proposed for receiving the thrust, of which one was to let the end of the shaft enter, in the manner of a piston, a tight cylinder of oil, so that it would be against a liquid only that the end of the shaft would press. Another expedient was to place a large collar upon the shaft, which would press against a number of balls or small rollers resembling the rollers of a swivelling bridge. Neither of these plans, however, has come into practical use; but one of two other modes is now generally followed. Either the thrust is received

upon a number of collars, which are recessed into a suitable bearing, or it is received upon a series of discs applied to the end of the shaft, and resting in a cistern of oil, as represented in fig. 10. The cistern is usually cast upon the base plate or some other solid part of the engine, and its end is sufficiently strong to bear the thrust of the screw. Interposed, however, between the end of the cistern and the end of the shaft are two, three, or more discs of metal, usually about two inches thick, and of the same diameter as the shaft itself. A bolt passes through their centres to keep them in a line, but they are each free to revolve upon this bolt; and where the shaft passes out of the cistern a collar of leather is applied, to prevent the oil from escaping. It will be obvious from such an arrangement that if the end of the shaft, where it presses upon the discs, begins to heat from undue friction, it will revolve with somewhat more difficulty, and will consequently carry the first disc round with it. The rubbing surfaces, therefore, are no longer the end of the shaft and the first disc, but the first disc and the second disc. In fact, the rubbing surface, instead of being confined to one disc, is distributed over several. Those surfaces, which begin to heat, and consequently to stick, will cease to rub, and thus they will speedily become cool again, and their efficiency will be soon restored. The more usual mode of receiving the thrust of the screw, however, is by a collar bearing, the collars being turned out of the solid shaft and the encircling bearing being generally of brass, but sometimes of wood. Bearing surfaces of wood for receiving the thrust were first introduced by Mr. Alexander Gray, engineer of the steamer Himalaya. The brass bearing of the collars being very much worn, Mr. Gray introduced rings of lignum vitæ between the collars on the shaft and the collars of the brass, these rings having been each introduced in four pieces and while the vessel was at sea.

Fig. 10.



Best Proportions of Screw.—For mercantile purposes screws with three blades are, on the whole, to be preferred. The diameter of the screw should be as large as it can be conveniently got, and when the area of the screw's disc—that is, the area of the circle described by the extremity of the arms of the screw—has one square foot of area for every $2\frac{1}{2}$ square feet in the area of the immerged midship section of the vessel, a very efficient performance is obtained. The pitch of the screw should be equal to the diameter of the screw, or a little more, and the length of the screw fore and aft should be that answering to one-sixth of a convolution. Thus, in the case of a screw twelve feet in diameter, the pitch would be twelve or fourteen feet, and the length of the screw measured along the axis would be about two feet.

Best Forms of Screw.—Screws are commonly made with a uniform pitch, and with the blades standing at right angles with the axis. A slightly progressive increase in the pitch, however, say to the extent of 5 per cent., appears to be advisable—i. e. the pitch of the screw at its leading end should be 5 per cent. less than at its following end. The pitch at the centre should also be 10 per cent. less than the pitch at the circumference, for the centre should merely screw through the water without seeking to produce any reacting force, which, from the great obliquity of the blades at the centre, could not be done with advantage. Finally, the blades of the screw should be bent a little astern, so as to produce in the particles of water which they force backwards a tendency to converge to a point. This tendency will balance the divergent tendency produced by the centrifugal action of the screw in its revolution, and the two forces, by balancing one another, will cause the water to be projected backwards from the screw in a cylindrical column. With the ordinary screw the water projected backwards assumes the figure of the frustum of a cone, and some portion of the power is thus lost.

Griffith's form of screw, as already explained, is formed with a large central ball and with blades narrower at the point than near the boss, so that each blade has a shovel form, and this species of screw is now much used. Perforated screws, corrugated screws, and many other kinds of screws have been tested since the earlier editions of this work appeared, without, however, the manifestation of any qualities which encouraged their adoption. In Rigg's screw the screw may be of the usual kind; but a series of radial blades, like another screw having twice the number of blades possessed by the screw itself, is fixed stationary behind the screw on the rudder post. These blades, set at the opposite angle from that of the blades of the screw itself, are pressed upon by the revolving column of water which the screw puts into rotation; and this revolving column, by pressing obliquely on the backs of the fixed blades, assists in forcing the ship forward. The rudder post may be made to constitute two of these fixed blades by twisting the portions of it beneath and above the shaft in opposite directions.

Positive and negative Slip of the Screw.—When a vessel is propelled by oars, paddles, or any other instrument which acts upon the water, it is obvious, that since the water is not a solid body which can resist without disturbance the application of force, there will be a certain amount of recession in the water, or, in other words, the water will be moved to a certain extent backwards, while the vessel is forced to a certain extent forwards. This backward movement of the water is what is termed *Slip*, and in its results it is analogous to the loss of power and speed which a locomotive experiences when the wheels slip upon the rails. This slip exists in the case of the screw as well as in the case of the paddle or other

species of propeller; and when the engines of a steam vessel are set in motion while the vessel is at anchor or moored in a river, the whole power of the engines is wasted in slip, or in moving the water without moving the vessel. The ordinary amount of slip in paddle vessels is about one-third of the whole distance travelled, or, in other words, the vessel would go one-third faster with the same number of revolutions if the wheels geared into an iron rack instead of gearing into water. In well-constructed screw vessels the slip is only ten per cent., or, in other words, the vessel would only go one-tenth faster with the same number of revolutions if the screw worked in an iron nut instead of working in water. Since, therefore, all the power expended in producing slip is lost, and since there is less slip with the screw than the paddle, there is an apparent superiority in the screw from this cause. In some screw vessels, however, the apparent slip is nothing at all, and in others it is less than nothing, or, in other words, the vessel is propelled through the water by the screw alone at a greater velocity than if the screw worked in a solid nut with the same number of revolutions. In the early history of the screw propeller, this apparent paradox provoked much incredulity, but the phenomenon is now understood, and is not difficult of explanation.

When a vessel passes through the water, the friction of the bottom and the sides puts a column of water in motion which proceeds in the direction of the vessel. Sea-weeds and other light objects adhering to a vessel have been observed to stand out straight from her side when the vessel was moving through the water with a considerable velocity, thus making it clear that a film of water must be moving with the vessel. The vacuity also which the motion of the vessel through the water tends to produce at the stern causes a flow of water towards the stern in order to fill it up. It follows, therefore, that a vessel, in passing through the water, puts in motion a stream or current which follows in her track; and that this is no hypothetical supposition is proved by the fact that a boat will often follow a vessel without being towed by a rope, and that when a slow steamer gets into a swift one's wake the slow steamer will not fall into the distance, but will be towed by the current which the leading steamer creates. Now, in a screw vessel the screw works in this current; and if from the form of the stern or other causes the current runs at a considerable velocity, and if from the large dimensions of the screw or otherwise the actual slip of the screw be small, then it will often follow that the slip of the screw will *appear* to be less than nothing, or negative, if the comparison be made not with the current, but with the stationary water at the ship's side. The screw must at all times have slip *relatively with the water in which its works*; but if that water is itself in motion, it is not surprising that the vessel should travel through a greater distance than what answers to the pitch and revolutions of the screw, any more than that a paddle vessel in descending a river with a strong current should pass through a greater distance than what answers to the diameter and revolutions of the wheel, if the distance travelled be measured on the river bank. A log placed where the screw revolves will always show that the screw advances with a greater velocity than the vessel as measured at that point, or, in other words, that the screw passes through the current with a greater velocity than the vessel passes through the current, though of course the speed of the vessel and of the current together may be greater than the speed of the screw alone.

Further, the screw acts upon water moving inwards towards the stern, while the hydrostatic and hydraulic heads of water are not the same. The moving water will be higher than the stationary, that the two may be in equilibrium; and the arrested momentum of the two converging streams where they meet will raise the level of the water at the stern and force the vessel on by hydrostatic pressure. The same action will ensue if the screw be made with a very fine pitch, for the centrifugal force of the adhering water will in such case raise a wave against the stern; the velocity of rotation of the screw being greater, the smaller the pitch. Fine pitches, blunt sterns, the action of sails, and many arms in the screw, unless the pitch be at the same time made very coarse, all conduce to the creation of negative slip, which is caused mainly or wholly by the interference of the vessel and not by the action of the screw itself. Mr. Rankine, Mr. Froude, Mr. Reed, and others, have endeavoured to explain the phenomena of negative slip, which, however, is mainly imputable to the causes enumerated above.

Measure of the Thrust upon the Screw Shaft, and Amount of Power lost by Slip.—In some vessels a dynamometer has been applied to the end of the screw shaft, and it has thus become possible to measure accurately the amount of forward pressure exerted by the screw. In the Rattler, a vessel of 888 tons burden, this pressure amounted, on an average, to about four tons. This pressure, multiplied by the space passed through by the vessel per minute, and divided by 33,000, will manifestly give the force in actual horse power that is instrumental in the propulsion of the vessel, and the power thus computed amounts, on an average, to about half or two-thirds the power developed in the cylinders. It hence appears that, in screw vessels such as the Rattler, from one-third to one-half of the engine power is wasted in slip and in the friction or other resistances caused by the revolution of the screw in the water. With the paddle wheel the loss from these causes is nearly the same, and the screw and paddle consequently produce about the same speed by the application of the same amount of power.

Relative Efficiency of the Screw and Paddles.—To determine the relative efficiency of the screw and paddle as a propeller, two vessels, the Rattler and the Alecto, were constructed of about the same power, 200 horses, and of nearly the same size and form; but the Rattler was a screw vessel, and the Alecto a paddle vessel. The Rattler, it was found, had, in nearly all cases, somewhat the advantage in point of speed, but the engines of the Rattler also exerted somewhat more power. Subsequently two other vessels, the Niger and Basilisk, were constructed of 1,072 tons, and 400 horse power, the Niger being a screw vessel, and the Basilisk a paddle vessel, and the following were the results obtained:—In deep immersions the screw vessel had an advantage of 1¼ per cent. over the paddle vessel, but with medium immersions the paddle vessel had an advantage of 1¾ per cent. over the screw vessel, and in light immersions the paddle vessel had an advantage of 4¾ per cent. over the screw vessel. The slip of the screw was 24 per cent. Upon the whole, therefore, the screw seems to have somewhat the advantage when the vessel is deep, and the paddle seems to have somewhat the advantage when the vessel is at a light or medium immersion.

Screw Vessels not adapted to go Head to Wind.—The experiments with the Rattler and Alecto established one important fact in connection with screw vessels, viz. that they are ill adapted to advance against a head wind. For, although both vessels attained the same speed of 4 knots against a strong head wind, yet, in the case of the Alecto, this performance was attained with a velocity of the engine of 12 strokes per minute; whereas, in the Rattler, it was only attained with a velocity of the engine of 22 strokes per minute. It follows, therefore, that a screw vessel in proceeding head to wind will require 1·8 times, or nearly twice the quantity of fuel to do the same amount of work. The screw, in fact, revolves at nearly the same velocity whether the wind is adverse or favourable, or whether the vessel is lying at anchor; and this is a serious defect in the case of vessels intended to encounter adverse winds. In the case of vessels, however, which use the screw only as a resource in calms, or as an auxiliary to the sails, this disadvantage will not be experienced, since such vessels have no pretensions to the capability of proceeding in direct opposition to a strong head wind, and the evil will be diminished if the screw be immersed deeply in the water, as may best be done when twin screws set in the quarters are employed.

Paddle and Screw Vessels tied Stern to Stern.—In all cases where screw and paddle vessels of equal power and size have been tied stern to stern, the screw vessel has preponderated, and towed the paddle vessel so soon as the engines were set on. When the Rattler and Alecto were tied together in this manner, the Alecto's engines were set on first, and she was allowed to tow the Rattler at the rate of 2 knots an hour. The Rattler's engines were then set on. In five minutes the two vessels became completely stationary. The Rattler than began to move ahead, and towed the Alecto against the whole force of her engines, at the rate of 2·8 knots per hour. In like manner the Niger towed the Basilisk astern, in opposition to the force of her engines, at the rate of 1·1 knots per hour. The natural inference from this experiment would be that the screw is more suitable for towing than the paddle; yet this inference is not confirmed by experiment. For, when the Niger and Basilisk were each set to tow the other alternately, in the usual manner in which a steamer tows a ship, it was found that the Niger towed the Basilisk at a speed of 5·63 knots, with 593·9 horse power, and that the Basilisk towed the Niger at the rate of 6 knots, with 572·3 horse power. The paddle vessel, therefore, accomplished in towing the largest speed with the least power. It has also been found that when a paddle and screw vessel set stern to stern push one another instead of pulling one another, the paddle vessel preponderates, whereas, if they pull, the screw vessel preponderates. These circumstances seem to show that the power of a screw vessel to tow a paddle vessel astern, when the two are tied together, does not arise from any superior tractive efficacy of the screw itself, but is due to the centrifugal action of the screw, which raises the level of the water at the stern, so that the vessel gravitates down an inclined plane.

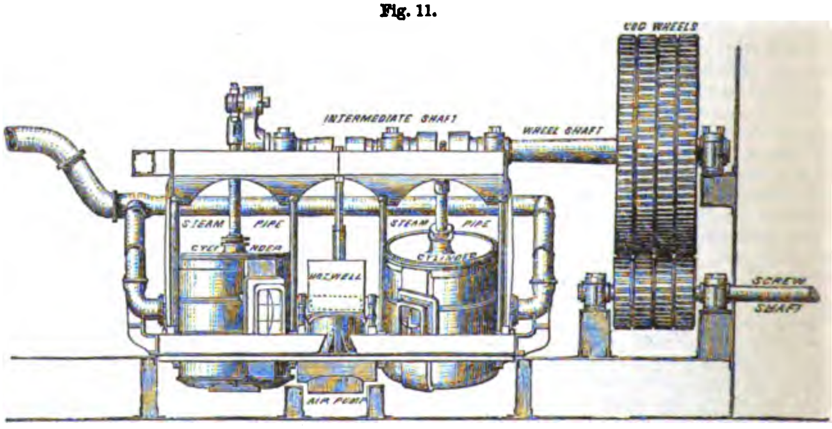
Cause of the serrated Outline of the Dynamometer Diagram.—In those screw vessels which have had a dynamometer applied to the end of the shaft the thrust of the screw was made to act upon a spring, and a pencil in connexion with the shaft marked a line upon a revolving cylinder, which line was either high up on the cylinder, or low down, as the thrust of the screw increased or diminished. The line thus traced, instead of being tolerably uniform and straight, was found to be serrated, like the teeth of a saw; and, on further investigation, it was discovered that every time the screw, in its revolution, brought the blades into the vertical position, and therefore into a line with the stern post, at that moment the thrust was increased. This phenomenon appears to be due to the circumstance of the water immediately behind the stern post being carried forward with nearly the same velocity as the vessel itself; and when the screw comes into that dead water, as it is termed, it is no longer a reaction answering to the *difference* of speed of the screw and vessel that it has to encounter, but a reaction answering to nearly the *whole* speed of the vessel. If such a reaction had to be encountered through the whole revolution of the screw, the velocity of its rotation would be necessarily diminished until the reacting pressure produced was balanced by the pressure on the pistons of the engine. But the momentum of the machinery and of

the screw itself momentarily carries up the thrust to a higher point than that due to the pressure on the pistons. If a screw vessel be reversed until she attains full speed astern, and be then suddenly changed to full speed ahead, it will be found that a dynamometer diagram, taken at that point at which the vessel is stationary in the water, from the effort to overcome her own momentum, will have a straight, and not a serrated line.

Importance of making the Stern of Screw Vessels very sharp and fine.—The preceding remarks will have very clearly indicated the importance of making screw vessels as sharp as possible at the stern; but the following facts may be stated in corrobation of the propriety of such a configuration: In 1846 the Dwarf, a screw steam vessel, with a fine run, was filled out in the stern by the application of three successive layers of planking, so as to alter the shape to that of a vessel with a full run. Prior to the alteration the speed of the vessel was 9·1 knots per hour, the engines making 32 revolutions per minute. The effect of the filling was to reduce the speed to 3·25 knots per hour, with a speed of the engine of 24 revolutions per minute. One layer of filling was then taken off, and the speed rose to 5·75 knots per hour, the engines making 26·5 revolutions per minute. When the whole of the filling was removed the speed rose to 9 knots, as before. Care was of course taken in this experiment to bring the filling into conformity with the lines of the vessel, so that there should be no roughness or abruptness to aggravate the evils of a full run. Again, the Sharpshooter and Rifleman were sister vessels of 486 tons, and 200 horse power, but the Rifleman was made with a full run, and the Sharpshooter with a fine run. The speed of the Rifleman was found on trial to be 7·9 knots, and of the Sharpshooter 9·9 knots. The Minx and Teazer were sister vessels of about 300 tons and 100 horse power, but the Teazer was made with a full run, and the Minx with a fine run. The speed of the Teazer was found to be 6·3 knots, and of the Minx 7·8 knots. The sterns of both the Rifleman and Teazer were sharpened subsequently to these trials, and the 100 horse engines of the Teazer were at the same time put into the Rifleman, while new engines of 40 horse power were put into the Teazer. Both vessels went faster than before. The Rifleman, when sharpened at the stern, attained a speed of 8 knots with engines of 100 horse power, whereas she had before only attained a speed of 7·8 knots with engines of 200 horse power. The Teazer when sharpened at the stern, attained a speed of 7·685 knots with engines of 40 horse power, whereas she had before only attained a speed of 6·3 knots with engines of 100 horse power. The engines of the Teazer, when transferred to the Rifleman drove that vessel nearly 2 knots an hour faster than they had previously driven the smaller vessel, an amelioration consequent altogether upon the sharpened form of the stern.

Engines for driving the Screw.—It will be obvious, on looking to the pitch of an ordinary screw, and the speed with which the vessel passes through the water, that the screw must revolve with a considerable velocity. For example, if a vessel be driven 10 miles an hour, or 880 feet per minute, by a screw of 12 feet pitch, then the screw must make somewhere more than the twelfth part of 880, or 73 revolutions in the minute. This is a much higher speed than marine engines have been heretofore accustomed to travel at, and two methods of obtaining the necessary velocity of rotation have been adopted. In the one, the construction and speed of the ordinary engine have been retained without material

Fig. 11.

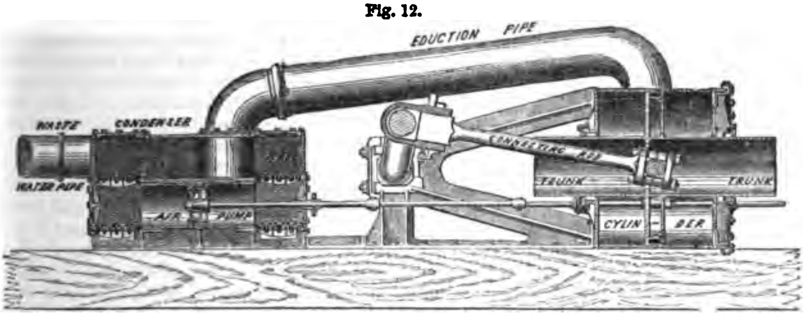


alteration, and the required velocity of revolution has been given to the screw shaft by means of intervening gearing. In the other case, a new arrangement of engine has been introduced which is capable of moving with a much greater velocity than ordinary engines,

and the engine and screw shaft are directly connected with one another. Fig. 11 represents a pair of geared screw engines, being the engines constructed by Messrs. John Penn and Son for the Great Britain. These engines are on the oscillating principle, which Messrs. Penn have rendered so celebrated, and they are almost identical in construction with the paddle engines made by Messrs. Penn for the Sphinx and other vessels. The Great Britain is of 3,500 tons burthen, and her displacement, at 16 feet draught of water, is 2,970 tons. The diameter of cylinder is 82½ inches, length of stroke 6 feet, nominal power 500 horses, diameter of screw 15½ feet, pitch of screw 19 feet, length of screw 3 feet 2 inches. The screw has three arms or blades. The multiple of the gearing is 3 to 1, and there are 17½ square feet of heating surface in the boiler for each nominal horse power of the engine. The crank shaft, being put in motion by the engine, carries round the great cog wheel or aggregation of cog wheels affixed to its extremity, and these wheels acting on suitable pinions on the screw shaft cause the screw to make three revolutions for every revolution performed by the engine.

Fig. 12 is a representation of a pair of

Fig. 12.



direct-action screw engines, being the engines constructed by Messrs. John Penn and Son for H.M.'s screw frigates Arrogant and Encounter. Here the cylinders lie in a horizontal position, and are traversed through the centre by a pipe or trunk, upon which the piston is cast. The central trunk is circular, and it projects through both the top and bottom of the cylinder, the points of penetration being made tight by suitable packing. One end of the connecting rod is attached to the centre of the trunk, while the other end engages the crank, which turns round the screw shaft. The air-pump, which also lies in a horizontal position, is double-acting, and is situated within the condenser. A large pipe, called the eduction pipe, leads the steam from the cylinder to the condenser, where it is condensed by a jet of cold water, and the hot water thence resulting is ejected by the air-pump through the waste water pipe, and passes overboard. In the figure only one cylinder and one air-pump are represented, but it will be understood that there are two cylinders and two air-pumps. The valves by which the water is admitted to the air-pump from the condenser and passes again from the air-pump into the hot well and waste pipe, consist of several discs of Indian-rubber, kept down by a central bolt so as to cover radial slits or orifices in a perforated plate. These valves are found to operate without noise or shock, notwithstanding the high speed at which the engine must work in order to give motion to the screw without intervening gearing. The diameter of the cylinder in the Arrogant and Encounter is 60 inches, and the diameter of the trunk 24 inches, which, being deducted, leaves an available area of piston equal to that of a piston 55 inches in diameter. In the Arrogant the length of stroke is 3 feet, and the Encounter is 2 feet 3 inches. The nominal power of both engines is 360 horse. The diameter of the screw of the Arrogant is 15 feet 6 inches, and the diameter of the screw of the Encounter is 12 feet. The pitch of both is 15 feet, and the length 2 feet 6 inches. The Arrogant is a vessel of 1,872 tons burden, and the Encounter of 953 tons. Both the engines and boilers are kept below the water-line, so as to be out of the reach of shot. Engines similar to this, but of greater power, have been constructed by Messrs. Penn for the Warrior, Black Prince, Minotaur, Achilles, Bellerophon, Northumberland, &c. But the use of a trunk which passes into the steam and then into the atmosphere at every stroke, is not conducive to economy of fuel.

The forms of engine, both geared and direct-acting, for giving motion to the screw, are too numerous to be here described. But in most war vessels the cylinders are placed upon their sides, so as to keep the engines below the water-line. In merchant vessels a form of engine like the land beam engine, with the cylinder at the one end of a beam and the connecting rod at the other—the connecting rod extending downwards from the end of the beam to give motion to the crank—is frequently employed. In other cases the cylinder is inverted, and a connecting rod proceeds from the end of the piston rod to turn the crank, the end of the piston rod being, of course, steadied by suitable guides.

In the edition of this work published in 1852, it was pointed out that in horizontal engines, like those of Messrs. Penn and Son, it would be better to place the trunk in the air-pump instead of in the cylinder; and a form of engine of this kind was subsequently patented by Messrs. Robert Napier and Sons, of Glasgow, and was introduced by them into several vessels. The overhead, or forge hammer engines, as they are sometimes called, constructed by Messrs. Caird & Co. for the Bremen, Hansa, and other transatlantic vessels, and by Messrs. Napier and Son for the Pereire and Ville de Paris, have been highly efficient and economical. But that species of engine is not adapted for ships of war, as it rises above the water-line; and the form of horizontal engine originally designed by Mr. Holm in 1844 for the Amphion, and introduced into the merchant service by Mr. Bourne in 1853, is now the form of engine most generally adopted for all purposes whether of war or commerce by marine engineers. Mr. Bourne, in 1853, first introduced the plan of balancing the momentum of marine engines by counterweights attached to the crank; and soon afterwards Mr. Penn introduced similar counterweights into the engines of the Himalaya, and they have since become general. The Amphion form of engine is virtually a steeple engine, as it is called, laid on its side. The cylinder is horizontal and two piston rods, one above the shaft on one side of the crank, and the other below the shaft on the other side of the crank, proceed to engage a cross head which moves horizontally in guides on the opposite side of the crank. From this cross head a return connecting rod proceeds to the crank, and heavy weights are attached to the side of the crank which is opposite to the crank pin, to balance the momentum of the piston and its connections. This form of engine is now adopted by Messrs. Maudslay, Ravenhill, Napier, Day, and other leading marine engineers.

Screw Vessels with Auxiliary Power.—We have already stated that screw vessels, intended to go head to wind and to contend against head seas, are not so efficient as paddle vessels, inasmuch as they require more coal to do the same work. Under the conjoint influence of sails and steam, however, they are under most circumstances as efficient, and, if deeply laden, are more efficient. A screw vessel being divested of paddle boxes, partakes more of the character of a sailing ship; nevertheless, from the experiments with the Niger and Basilisk, it does not appear that a screw vessel is more efficient under sails than a paddle vessel, although such a result might naturally be expected. The advantages incident, therefore, to the use of screw vessels with auxiliary power do not result from any superiority of the screw as a propeller, nor from the increased facilities which it presents for the application of sails, but are to be ascribed to the large employment in screw vessels of wind power, which costs nothing, instead of steam power, which costs much, and also to the maintenance of lower rates of speed than are thought necessary in paddle vessels. The screw, indeed, is a less cumbrous propeller than the paddle, and, in consequence of the high speed of engine which it permits, a very considerable engine power will go into a small compass.

Screw Vessels with Auxiliary Power.—The use of the screw as an auxiliary propeller to sailing ships was at one time regarded as among its most promising applications, and vessels were accordingly made with hoisting screws or with feathering screws, to enable the screw to be raised out of the water, or the blades to be set in a line with the keel when the vessel was under sail alone. Practically, however, vessels fitted with screws and engines have maintained them in constant action, and have contented themselves with working the steam very expansively in the cylinders in fair winds, so as under those circumstances to save the coal. The liability of derangement of all kinds of hoisting and feathering apparatus has been a serious discouragement to the perpetuation of such plans, and although screw vessels are still made of small power as well as of large power it cannot be said that any auxiliary screw vessels are now employed in the sense of the screw being put wholly out of action in fair winds. The want of some propelling apparatus of small power which would be able to drive forward a sailing ship in calms is still much felt, especially in the case of vessels which require to cross the line. But a screw placed beneath the water at the stern is not the most eligible expedient for that purpose, as it would require to be large and cumbrous to obviate a wasteful amount of slip; and there is a settled objection in the case of sailing vessels to the introduction of machinery into the hold, and to the perforation of the vessel by shafts and pipes for the sake of a benefit which may only be realised for a few days during the whole voyage. Mechanism for this kind of auxiliary propulsion should be situated upon the deck, and the boiler should be combined with the cooking and distilling apparatus, so as to be as generally useful as possible. The most convenient apparatus would probably be a large and broad vertical oar set on each side of the vessel and moved slowly outward and inward with a sculling action like the action employed in propelling the ancient galleys. The oar would require to be feathered at every stroke, which would be done by bending the arm or by placing more of the blade on one side of the vertical axis than upon the other. For coasting purposes, screw vessels of moderate power have not only superseded paddle steamers but also sailing ships to a considerable extent, as they are found on the whole to carry more cheaply.

Twin Screw Vessels.—Many screw vessels are now constructed with a screw projecting through the vessel at each quarter, instead of employing a single screw at the stern, and this plan has the advantage that the necessary propelling area may be got at a lower

depth, while by turning one screw ahead and the other astern the vessel may be turned as on a pivot without any aid from the rudder. In some cases, the body of the vessel is split near the centre, and each division terminates in a stern of its own, with its own screw and rudder. In other cases, the screw shaft protrudes through the oblique run of the ship on each side, and its outer end is supported by a suitable wrought iron frame, while the rudder is set in the usual place. For war purposes, double screws present many advantages. They afford more power of rapid evolution; by being more sunk in the water, they are more out of the reach of shot, and the vessel will not be disabled if the rudder or one of the screws should be damaged or destroyed. The Kalamazoo class of American Monitors is built with double screws 15 feet diameter. Each vessel carries two turrets 26 feet diameter, and 15 inches thick of iron, and the side armour is of iron 14 inches thick.

Conditions to be observed in the Construction of Screw Vessels.—The whole of the superior eligibility of screw vessels for the conveyance of merchandise, whether compared with paddle vessels or sailing ships, is not due to the action of the screw itself or to the use of steam power. Much, probably most, of it arises from the superior form of a vessel which has been simultaneously introduced, and by which the sails have been rendered much more efficient than heretofore in urging the vessel through the water. The main conditions necessary to the satisfactory performance of screw vessels lie in making the form of the vessel sharp and fine, in applying a large amount of sail power, and in keeping the screw well immersed in the water. Screw vessels should be broad at the water line, so as to enable them to bear the pressure of a large amount of sail; and the sails should be as flat as possible, and be laced to the spars, so as to enable the vessel to go as near as possible to the wind. The rigging of all vessels is still in a most defective state. It is without any provision whatever for using up the power of the wind in an effectual manner, and a large proportion of that power is consequently lost. Under suitable arrangements, vessels would be able to sail directly against the wind, instead of having to tack, as is at present the practice; and there is every reason to believe that, before many years, expedients for this purpose, and for obtaining from a given force of wind and area of sail a much larger propelling effect, will be applied.

For further information respecting the screw propeller see a *Treatise on the Screw Propeller*, by John Bourne, C.E., third edition, 1866, from which the engravings and most of the information given in this article have been extracted. See also Admiral Paris's report on the naval architecture in the Exhibition of 1862 (*Rapport sur l'Art Naval en* 1862).

Screw Surface. [HELICOID.]

Scribe (Lat. scriba). The copyists, and at the same time the interpreters of the law, in the later periods of the Jewish history, were called Scribes. In the New Testament, we find them generally mentioned in connection with the Pharisees, with the leaders of which sect, together with the High Priests, they appear to have constituted the Sanhedrim. In addition to their other functions, they were concerned in education, and in reading and expounding the law to classes of pupils in the outer courts of the temple. Some ancient writers conceive the scribes to have formed peculiar sects by themselves; but there is no authority for this opinion.

Scribing (Lat. scribo, *I write or scratch*). In Architecture, fitting the edge of a board to another board in the same plane as the edge. In joiner's work, it is the fitting one piece of wood to another so that their fibres may be respectively at right angles.

Script (Lat. scriptus, *written*). In Printing, a kind of type cast in imitation of writing. The French call it *Anglaise*. There is no character of type on which so much labour has been bestowed as on this. The old scripts were cast on square shanks, the ascending and descending letters being *kerned*, and therefore liable to be broken off. In 1815, Messrs. Firmin Didot & Sons introduced a new script cut with great freedom and cast on a rhomboidal shank, with triangular blocks having a corresponding angle on one side, and the other two sides forming a right angle, with which to *justify* the beginnings and ends of lines. Messrs. Laurent and Deberney, French artists, about thirty years since introduced a new square-bodied script called *Américain*, so beautifully cut and managed, that the effect produced when worked is excellent. The *kern*, instead of being unsupported, is protected by the shank of the letter, having two angles thrown out at the head of the two opposite corners of the body, so as to give support to both ascenders and descenders; the opposite angles of the letters are cast with a corresponding slope to receive the kerned letters without their incurring any danger of riding upon each other.

Scriptures, Holy. The name commonly used to designate the writings of the Old and New Testaments, which are comprised in the CANON. [BIBLE.]

Scrivener (Span. escribano, from Lat. scribo, *I write*). Money scriveners, in old English usage, were persons who received money to place it out at interest, and supplied others, who wished to borrow, with money on security, a class of business now undertaken, in different departments, by bankers, money-brokers, and solicitors. The last regular scrivener is said to have been a person of the name of Jack Ellis, a contemporary of Dr. Johnson, mentioned in Boswell's *Life*. The city company of scriveners remains to attest the ancient importance of the business.

Scrobicularia (Lat. scrobiculus, dim. of scrobs, *a ditch*). A genus of Dimyarian Acephalous mollusca, allied to *Psammobia*.

Scrofula. This disease was termed by the Greeks αι χοιράδες, *swollen* or *indurated glands of the neck*, to which it was said that the pig (χοῖρος) is especially subject. Hence the Latin term *scrofula* has been traced to scrofa, *a sow*; but the origin is in either case very dubious, the Greek word being akin, perhaps, to χέῤῥος, *hard*, and the Latin to scrupus and rupes, *a stone* or *pebble*.

It is now regarded as the result of a general disorder to which the name *tuberculosis* is given. The blood is diseased, and according to the age of the patient different organs are liable to become attacked by tubercular deposit. In early infancy this deposit gives rise to water on the brain. In early manhood pulmonary consumption is the result, while in the intermediate period of life we find mesenteric disease appearing. The popular use of the word *scrofula* consists more especially in its application to tuberculosis in children. It is most common among delicate children with fair complexions, and those disposed to rickets. It is rare in warm climates, and seems to be favoured by cold and variable countries. It is promoted by everything that debilitates; and when its exciting causes are by any accident not brought into action, it may even remain dormant through life, and not show itself till the next generation. In mild cases the glands, after having suppurated, slowly heal; in others the eyes and eyelids are inflamed, and the joints become affected, the disease gradually extending to the ligaments and bones, and producing a hectic and debilitated state, under which the patient sinks; or it ends in tuberculated lungs and pulmonary consumption. In the treatment of the mild and simpler forms of scrofula, the diet should be nourishing and invigorating, and a dry situation and sea air are to be sought for; great attention should be paid to the clothing, so as to avoid colds and coughs; and tonics and gentle stimulants, with mild narcotics, and occasionally the alkalis, should be prescribed. Iodine has sometimes appeared of much service, but it requires the greatest circumspection in its internal use; it may be applied externally, as may also sea-water and other saline lotions. Chalybeates and mercurials are frequently prescribed; and much benefit has, in some instances, been derived from a course of sarsaparilla.

Scroll (Fr. écrou). In Heraldry, that part of the outward ornaments of a shield or achievement on which the motto is inscribed.

Scroll. In Shipbuilding, curved pieces of timber bolted to the knee of the head by way of ornament. In old naval works the word is written *scrow*.

Scrophulariaceæ (Scrophularia, one of the genera). A natural order of herbaceous or shrubby Peryginous Monopetalous Exogens, of the Bignonial alliance, inhabiting all parts of the world, except the coldest. The stamens are either didynamous or unsymmetrical; nevertheless, the affinity of the order is undoubtedly with *Solanaceæ*, through the medium of the tribe *Salpiglossideæ*; so that it becomes necessary to separate them by a mere artificial distinction, considering as *Solanaceæ* all such genera as have a plaited corolla, and five stamens, and as *Scrophulariaceæ* all those in which the fifth stamen is wanting, or the æstivation of the corolla imbricated. They are generally acrid bitterish plants. The leaves of some are purgative, and even emetic, while some, as *Digitalis*, are highly poisonous. Nearly all the tribe turn black in drying. Many of the genera, such as *Digitalis*, *Calceolaria*, *Pentstemon*, *Veronica*, *Mimulus*, &c., are valued by gardeners for their beautiful flowers.

Scrotum (Lat.). The membranous bag in which the *testes* or chief male organs of generation are suspended in the higher vertebrate animals.

Scruple (Lat. scrupulus, dim. of scrupus, *a rough stone*). A denomination of weight; the third part of a dram, and equal to twenty grains. [Weights.]

Scrutiny (Lat. scrutinium, from scrutor, *I examine*). In Parliamentary language, an examination of the votes given at an election by an election committee, at which the bad given on both sides are rejected, and the poll corrected accordingly.

Scrutiny. In the Primitive Church, an examination in the last week of Lent of the catechumens who were to be baptised on Easter-day; used chiefly in the ancient church of Rome.

Scud (Dan. skud, Swed. skudda). The name given by seamen to loose vapoury clouds driven swiftly along by the winds. *To scud*, signifies to run directly before the wind in a gale. As the object is to keep before the sea, the fore sail or foretop sail is set; the latter or the maintop sail is often necessary, as the fore sail is often becalmed from the height of the waves. *To scud with bare poles* is to run before a storm without any sail set.

Scudo. [Money.]

Scull. In a fresh-water sense, an oar, so short that one man can work a pair. In its sea meaning, it generally implies an oar placed over the stern of a boat, and worked from side to side; the blade, which is turned diagonally, being always in the water. The action on the water resembles that of the Archimedean screw. In China, where this method is well understood, large boats are impelled by a single scull with considerable velocity.

Sculpture (Lat. sculptura, from sculpo, *I carve*). The art of carving in wood, stone, or other materials. The origin of this art is a subject not less obscure than the early history of Music and Painting: and it is useless to attempt to arrive at historical conclusions, where the materials from which they might be drawn do not exist. But without venturing to determine the age at which the distinction was first established, we may classify sculptured works from the first into the two forms of carvings whether in intaglio or cameo, and of independent statues or figures. The former

branch of the art was much more practised in ancient than in modern times, owing to the universal use of seal rings, which having at first been rude signs, without meaning, and sometimes merely a square or round hole, were at length brought to perfection in the age of Phidias and Praxiteles.

The carving of independent figures seems to have been long confined to representations of deities; but we have no means of determining how long such carvings remained symbolical, or of ascertaining the age in which strictly imitative figures were introduced. It has been supposed that phrases in the Homeric poems, as in *Iliad*, vi. 303, denote the existence of imitative statuary; but this is at the least doubtful. The point of such passages lies in the placing of the peplus or robe on the figure, whatever it may have been; and as we know the use to which the PEPLUS was put in the Panathenaic festival, we are scarcely justified in assuming the existence of a more advanced art in the Homeric age, on the mere strength of a conventional epithet.

The symbolical images of gods were blocks, stones, staves, or beams. 'It was thus,' says Dr. Thirlwall, *History of Greece*, ch. vi., 'that the god of love was worshipped at Thespiæ, the goddess of beauty at Paphos, the Graces at Orchomenus, Zeus and Artemis at Sicyon, the Twins at Sparta.' These blocks or masses of stone were all conical in shape, like the images of Baal worshipped by the Phœnician and Canaanitish and Assyrian tribes. This cone was reproduced in the wooden Ashera set up in the Jewish temple at Jerusalem, on the stone altars of Baal, like the LINGA of the Hindus on the conventional representation of the YONI. These masses of wood or stone were further modified into poles or staves, which are known to have been objects of almost universal veneration. 'Even in the time of Pausanias the inhabitants of Chæronea paid higher honours to a staff, which they believed to be the sceptre of Agamemnon, described in the *Iliad*, than to any of the gods.' (Thirlwall, *History of Greece*, ib.) It is unnecessary to dwell on the connection between these conical blocks, whether of wood or stone, with the phalli or poles borne in the Dionysiac processions, or to say more than that the universality of the emblem seems to point to the conclusion that the first sculptured images or symbols were all phallic. These symbols spring up everywhere, and may in each country have led to the production of other symbols, and finally to imitations of the whole human figure. But except on distant historical evidence we have no warrant for tracing the art of one country to that of another; and the habit of tracing Greek art to Egypt seems to be in an especial degree delusive. There is not the slightest evidence that Greek civilisation, whether in music, painting, astronomy, or sculpture, was derived from the banks of the Nile, or from the cities of the great Mesopotamian plain.

This stage of the art, then, as confined to mere symbolic representation, may be dismissed as not properly belonging to the history of sculpture. Of the earlier carved works of the Jews, whether teraphim, cherubim, or any others, we do not know enough to be able to speak with certainty; but on the sculpture of the Assyrians the results of recent explorations have thrown a valuable light. From the works thus recovered from the ruins of Khorsabad, Khileh Shagat, Birs Nimrud, and other mounds, we learn that the conventional fetters which were never removed from any branch of Egyptian art were among the Assyrians confined chiefly to the representation of deities and kings. Hence in the delineation of the forms of men and beasts the Assyrian painters and sculptors attained an eminence second only to that of the Greeks. But the discoveries of Sir Henry Rawlinson, M. Botta, Mr. Layard, and others, although they carry back the history of Assyrian art to a period long preceding a contemporary history, leave the legendary annals of sculpture in the days of Ninus and SEMIRAMIS just where they were, mere fables from which no historical residuum can be extracted, even if it be contained in them.

The Nineveh marbles in the British Museum illustrate the kind of art referred to; these and those of Persepolis much resemble the Egyptian. As the Nineveh reliefs record the actions of Sennacherib in Judæa, they may be as early as the seventh century before our era, but not earlier. In Persepolis there are some extraordinary sculptures, bearing considerable resemblance to the style of the Egyptian bassi-rilievi in the palace of Thebes, allowing for the difference of dress; but they contain nothing in science or imitation particularly worthy of our notice. They appear, according to Diodorus, to have been executed by an Egyptian colony carried from Egypt by Cambyses. The earliest sculpture to which we can refer, and on which we can reason, is that of the Egyptians. The abundance and variety of the specimens still in existence of their sculpture, minute and colossal, domestic and religious, prove them to have been a nation with great resources. The greater portion of their sculpture seems to have been sacred, i. e. representations of the divinities and their attributes and qualities. Among their colossal statues, Herodotus mentions one before the temple of Vulcan at Memphis, and another at Sais, placed there by King Amasis, each of the height of seventy-five feet. The part of the sphinx, near the great pyramid, still out of the sand (i.e. from the throat upwards) rises to the height of twenty-five feet. At Thebes the sitting statues of Memnon, the mother and the sons of Osymandyas, are each fifty-eight feet high. A long catalogue might be added to these; we will, however, only add, that in the British Museum is a closed hand which must have been part of a statue sixty-five feet high. Grace of form, elegance, and symmetry, are

not to be found in Egyptian sculpture. The faces of their statues have a resemblance to the Chinese, and their bodies are formed with large bellies. They generally stand equally poised on both legs, having one foot advanced; the arms either hanging down straight on each side, or if one be raised, it is at a right angle across the body. Some of their statues are seated, and some are kneeling; the position, however, of the hands is rarely different from what we have described. The faces are generally flat; the brows, eyelids, and mouths formed of simple curves slightly marked, and with little expression. The tunics and draperies are frequently without folds.

The arts of Egypt seem to have been in a stationary state for many centuries previous to the invasion and subjugation of the country by Cambyses. Winckelmann thinks that there were two distinct styles; the first ending with the conquest just mentioned, and the second commencing at that period, and ending after the time of Alexander the Great. In the first of these styles he describes the forms as straight, stiff, and ungraceful. The sitting figures have the legs always parallel; the feet are squeezed together, and the arms fixed to the sides. In the females the left arm is generally folded across the breast, and the draperies exhibit very little skill or knowledge. In the second style the hands become more elegant; the feet are placed at a greater distance from each other, the arms hang more freely, and the figure is generally clothed with a tunic robe and mantle. The material usually employed is granite or basalt; the statues are not only formed with the chisel, but polished carefully: and the eyes are sometimes formed of different materials from the statues themselves. Small figures are frequently found, to which the name of penates has been given; they are sometimes composed of wood, sometimes of baked earth, and some are covered with a green enamel.

'Winckelmann,' says Flaxman in his Second Lecture on Sculpture, 'has remarked that the Egyptians executed quadrupeds better than the human figure; for which he gives the two following reasons: first, that as professions in that country were hereditary, genius must have been wanting to represent the human form in perfection; secondly, that the superstitious reverence for the works of their ancestors prevented improvement.' 'There are,' he continues, 'statues in the Capitoline Museum with as great a breadth, and choice of grand parts, proper to the human form, as ever they represented in their lions or other inferior animals. In addition to these observations on Egyptian statues, we may remark, the forms of their hands and feet are gross; they have no anatomical detail of parts, and are totally deficient in the grace of motion.' The Egyptian bassi-rilievi are commonly what are called sunk reliefs; they are usually sunk from the surface of the material employed, which practice most probably obtained from their being cut in very hard stone, such as granite or basalt, and from the distance at which they were usually placed above the eye. In the first case, cutting the ground away from the figure would have occupied quite as much time as carving the figure itself; and, in the second case, the range of the outline created a greater breadth of shadow and distinctness to the spectator. These bassi-rilievi, or hieroglyphics, when found on the walls of tombs, relate the profession, actions, and funeral of the deceased; on those of palaces they describe the wars, negotiations, triumphs, processions, trophies, with the civil, military, and domestic employments of kings; on those of temples they were the records of theology; and on obelisks they are hymns to the gods, or eulogies of their kings. The reliefs are invariably coloured. (Sir J. G. Wilkinson, *Ancient Egyptians, &c.*; Rosellini's *Monumenti dell' Egitto e della Nubia, &c.*; and Layard's *Monuments of Nineveh.*)

The only correct notion that can be obtained on the subject of Phœnician sculpture is from a contemplation of the medals of the Carthaginians, who were a colony from Phœnicia; though perhaps these may mislead us. The Phœnicians, known by the name of Canaanites in Scripture, were at a very early period advanced in civilisation. Beautiful in their own persons, they were, unlike the Egyptian races, themselves models for their artists, and their situation and character were favourable to the progress of the art. Their extraordinary and successful spirit of commerce led to its cultivation, and some of the statues that decorated their temples were celebrated in history. Winckelmann is of opinion that the Etrurians, or ancient Tuscans, carried sculpture to a certain degree of perfection much earlier than the Greeks. Etrurian art proves that the first attempts towards sculpture were in clay, of which innumerable specimens have been found in Rome and its environs: and as the Romans in the early period of their existence as a people were entirely ignorant of the arts, no doubt is left of these specimens being the work of the Etrurians or Volscians. Clay was for a long time the only material used—'nulla signa statuæve sine argillâ;' and Pliny and Varro tell us that the Hercules, the Jupiter Capitolinus, the quadriga on the top of his temple, and all the other statues of the gods before the temple of Ceres was erected, were 'Tuscanica omnia.' Many of the Etruscan statues bear so striking a resemblance to those of Greece, that antiquarians have thought it probable they must have been brought from that country, or from Magna Græcia into Etruria, about the period of the conquest of Greece by the Romans, when Italy became almost saturated with the magnificent spoils of art which that country yielded. The Etruscan sculpture is in two distinct styles of art. In the first or earliest style, the general lines, or contours, are exceedingly stiff and straight, and the attitudes exhibit anything but a feeling of ease in the figure: the form of the head is entirely devoid of beauty, the out-

lines not well rounded; their figures are almost invariably too slender; the form of the head is oval, the chin piked, the eyes flat, with some degree of tendency towards squinting. All these defects indicate an infant state of the art, and the very same defects are often seen in the works of the Gothic sculptors. The second style of Etruscan art is conjectured by Winckelmann to be contemporary with the age of Phidias; but this conjecture is in no way borne out or supported by proof. In this style the joints are strongly marked, the muscles raised, the bones perfectly distinguishable, and considerable knowledge of the science of anatomy is displayed. The statues of the gods are executed with delicacy, and there is a show of great power without violent distension of the muscles. The attitudes, however, are far from natural, and the action constantly overstrained. To this Millin adds a third period in the history of Etruscan art, commencing at the conquest of Greece by the Romans, at which time the Etruscan artists became acquainted with the works of the Grecians, and, adopting their style, became at first their imitators, and afterwards their rivals. To the Italian artists of this period Horace is supposed to allude in one of his satires. (Dennis, *Cities and Cemeteries of Etruria, &c.*; Winckelmann, *Storia delle Arti del Disegno presso gli Antichi*, Rome 1783.)

Before turning to the sculpture of the Greeks we may notice, as bearing some resemblance to the Egyptian sculpture, that of the Hindus. The stupendous excavations at Ellora, which have been mentioned in the article ARCHITECTURE, and those at Elephanta and other parts of India, are well known by representations which have been published in this country.

As we have seen, the first dawn of the art was on the soil of Phœnicia and Egypt: we have now to trace it in its meridian splendour on the shores of Greece.

Greek sculpture has usually been arranged under three epochs. Of the rude and unfashioned representations of the primitive or mythical ages, some mention has already been made, nor is it necessary here to touch upon the works of the so-called *Dædalids*, about which we can now form no just conception, except that the material employed by them was wood, their images being called ξόανα. About 580 B.C. it is said that Dipœnus and Scyllis, Cretans, became celebrated at Sicyon for their marble statues, which retained much of the ancient style in the advancing position of the legs, the general form of the figure, and particularly in the vertical folds of the drapery, the edges of which were zigzag. About a generation later Bupalus and Anthermus of Chios were distinguished for their work in metal throughout Greece. Soon after this period, sculpture received the most elaborate finishing, though the character of the face and limbs was not much changed from the tasteless and barbarous style of former times. Flaxman conjectures that the colossal busts of Hercules and Apollo in the British Museum may have been the works of Dipœnus and Scyllis. It is not difficult to conceive the progressive improvement in an art so much cultivated, between the time of which we are now speaking and the first epoch in which Ageladas, the master of Polycletus, appeared. This early or second period is well illustrated by the casts in the British Museum from the Æginetan marbles, discovered in 1812, and now at Munich. To this period belongs Ageladus, a native of Argos, and contemporary with Pisistratus. It was at this period that art approached the personification of ideal beauty by the choice of forms from many models, so that the excellence found in each might be combined in one. Its cultivation had become an object of necessity in most of the Grecian states, induced greatly by a practice, introduced about this era, of honouring with a statue every individual who had received three crowns in the public games. These figures of men were called ἀνδριάντες, the statues of the gods being ἀγάλματα. Such a custom afforded the artist the opportunity of contemplating some of the most perfect examples of living beauty, from which were afterwards deduced those canons of proportion on which all future art has been unable to improve. Within the interval of which we have just spoken appeared the sculptor Callimachus, to whom Vitruvius assigns the merit of having invented the Corinthian capital. [ARCHITECTURE.] 'The better drawing of the figure, with a more careful attention to its parts, more precision and variety of attitude, a less elaborate curling and dressing the hair, the form of the figure better shown through the drapery, are all certain signs of a near approach to the age of Phidias.'

The third epoch of sculpture among the Greeks was in the age of Phidias, who died 432 B.C.—a period peculiarly splendid in history, as abounding with statesmen, warriors, artists, philosophers, and poets. Athens, destroyed by the army of Xerxes, rose under the auspices of Pericles in renewed and far greater grandeur. Phidias was employed by Pericles in the superintendence of the public works; and the admiration of his powers was so universal with the ancients, that Quintilian says, speaking of his statue of Athena and the Olympian Zeus at Elis, 'Cujus pulchritudo adjecisse aliquid etiam receptæ religioni videtur, adeo majestas operis deum æquavit.' The sculptures of the Parthenon, now known as the Elgin marbles and in the British Museum, are generally considered the highest triumphs of the art of sculpture, and are assumed to be the work of Phidias and his scholars. Callicrates and Ictinus were the architects of the PARTHENON. [ACROPOLIS.] The great reputation of Phidias was founded upon his representations of the gods, excelling more in them than in human forms. In his CHRYSELEPHANTINE works in ivory and in gold he was unrivalled. Polycletus, a contemporary of Phidias, assisted in perfecting the style of the third epoch. He was of Sicyon, and especially celebrated for his Doryphoros, or lance-

bearer, and his Diadumenus, or youth binding a fillet round his head (now in the British Museum). The first was so esteemed by artists, that it was called the 'canon,' from which they studied their proportions. There is, however, some doubt whether it be this or another statue to which this honour was paid. Among the contemporaries of these great men were Phradmon, Gorgias, Myron, and Scopas of Elis. In a passage of Pliny, Alcamenes is classed with Critias and Hegias, as a rival of Phidias.

A fourth epoch, from about 360 B.C., is that in which we become acquainted with the names of Praxiteles, Scopas the Parian, and Lysippus, and in which the style termed by Winckelmann the *fine style* was introduced. The graces of youth and beauty were the delight of Praxiteles; and in his marble statues at the Ceramicus of Athens he is said to have excelled himself. His Venus of Cnidos was so endowed with charms, that her suitors came from all quarters to pay homage at her shrine. This statue, which had been rejected by the Coans on account of its being naked, was refused to Nicomedes by the citizens of Cnidos in payment of a debt of immense amount. It remained at Cnidos in the time of the emperor Arcadius, about 400 A.D. Flaxman, in his Lectures, says of it, that it 'seems to offer the first idea of the Venus de' Medici, which is likely to be the repetition of another Venus, the work of this artist.' A satyr, Cupid, Apollo sauroctonos (the lizard-slayer), and Bacchus leaning on a fawn, are known works of this master. The group of Niobe and her children, now at Florence, is ascribed both to Scopas and Praxiteles. Contemporary with Praxiteles was Lysippus, so celebrated for the group of horses still to be seen in the front of St. Mark's church at Venice. This epoch is not comparable in grandeur with its predecessor. The refinement of art was carried almost to its utmost limit: greater delicacy and voluptuousness may indeed have been, and was, introduced into the female forms, but in dignity and simplicity of feeling it is inferior to the wonderful productions of the age of Phidias. Statues were still painted at this time. [POLYCHROMY.] After this period several of the finest groups and statues were nevertheless executed: one of them, the Laocoon, now in the Vatican, is in a very high class of art, and perhaps not inferior to any group known. The principal schools of sculpture were those of Athens and Rhodes: from the latter school came the Laocoon, the Torso of Apollonius and the Colossus of Rhodes, by Chares, the scholar of Lysippus. Agesander, Polydorus, and Athenodorus, sculptors of the Laocoon, are great names of this school. The Toro Farnese, also at Naples, is the work of Apollonius and Tauriscus, sculptors of Rhodes. The Laocoon is supposed to have been made in the reign of the emperor Titus. To what extent the Rhodians were sculptors may be conjectured from the fact that the Romans carried off from their little island 3,000 statues. After the death of Alexander the Great, 324 years B.C., the arts of design seem to have declined from their meridian excellence.

Fifth Epoch.—The year 146 B.C. was signalised by the entire reduction of Greece under the dominion of the Romans. Sixty-six years previously a dawn of luxury and taste had opened at Rome by the introduction, through Marcellus, of statues from Syracuse; but though the increasing luxury of the Romans created a constant demand for fresh objects of the art, its history in the city is but a melancholy continuance of its decline. The only occupation then left for Greek artists was to be found in Rome, whither they were invited, and where very many of them were to be seen. Among them Pliny (l. xxxv. c. 12, and xxxvi. c. 5), mentions the name of Pasiteles, a sculptor, who wrote four volumes, containing a catalogue of the finest works of art known in his time. Pasiteles excelled as a statuary in metal. His silver statue of Roscius, and his vases, were highly celebrated. Arcesilaus, Zopyrus, and Aulanius Evander, all Athenians, were among his contemporaries in the Augustan age. The first of these, who excelled in marble, is extolled by Pliny for his care in modelling before he began upon the block. He was the friend of Lucullus, for whom he executed a group, described by Varro, representing a lioness with cupids sporting round her, and endeavouring to force her to drink.

Under Augustus, the art had not been entirely divested of grand and noble feeling; but after his time it partook very much of the character of his successors as they appeared. Licentious and obscene under the sway of the vicious, debauched, and cruel Tiberius, under Caligula it became so grossly flattering, that ancient Greek statues of the gods were decapitated to make room for the head of this emperor. Under Nero (to whom, however, we are perhaps indebted for the preservation of the Apollo of the Vatican and the Borghese gladiator, found in his villa at Antium) it became so extravagant, that he had himself cast by Zenodorus, as the Sun, a bronze image 110 feet high [COLOSSUS], to be placed before his 'golden house.' Vespasian cultivated the arts as well as literature. The Temple of Peace, which was really a temple of the arts, was by him decorated with the choicest specimens of Greek painting and sculpture. The reigns of his son Titus and of Trajan were also favourable to sculpture. The latter was the patron of Apollodorus, the architect. Trajan, moreover, had the liberality and good sense to erect statues in honour of the eminent men of his time. The works of this period were, however, rather architectural than sculptural, such as temples, palaces, triumphal arches, &c., and the sculpture chiefly in request was for their decoration; a want certainly calculated not so much to

retrieve the art from its sinking state as to encourage bold and off-hand execution at the expense of simplicity and expression. Hadrian not only restored the principal buildings at Athens but completed the temple of Jupiter Olympius and richly adorned the interior with statues, some of which were chryselephantine. The statue of Antinous, so generally known, was the work of this reign. Antoninus and Marcus Aurelius were appointed by Hadrian as his successors: under them the art revived for a time, and has acknowledged her gratitude to the last by his bronze statue at the Capitol. How sculpture was encouraged at this time may be gathered from the innumerable busts of these emperors that have reached us. Commodus had likewise been honoured with a multitude of statues, but these upon his death were ordered by the senate to be all destroyed. Under Septimius Severus the decay of the art became very manifest: its decline continued during the reign of Alexander Severus, though two busts of him, which were discovered a few years since, are not without merit. During the next half-century, the rapid succession of twenty emperors, scarcely one of whom died a natural death, left but little chance of a revival of sculpture. By the end of the fourth century it was nearly extinct, a fact of which no other proof is necessary than the arch of Constantine and the statues of that prince, through whose removal of the capital of the empire to Constantinople, Rome no longer swayed the sceptre of the fine arts. If the Romans do not deserve the admiration in which the Greeks are held for their knowledge of the fine arts, they deserve our gratitude for their instrumentality in preserving some of the noblest productions of the art of sculpture. There are two epochs under which the taste of the Romans for the fine arts may be classed: the first beginning with the capture of Syracuse by Marcellus, and ending at the time of Julius Cæsar; the second, that of the Augustan age, in which all the polite arts flourished.

During the early Christian period when Constantinople became the capital of the arts, and to it were gathered the chief monuments of ancient sculpture, little progress was made in the creation of new works; and during the seventh and eighth centuries nearly all that was preserved of the old was destroyed by the fanaticism of the Iconoclasts. The conquest of Constantinople by the Venetians, in 1204, the consequent dispersion of Byzantine artists, and the developement of an eastern trade, gave quite a new life to the arts, and the dawn of the classic renaissance extended over the whole West as early as the thirteenth century. This was more decidedly the case in painting and sculpture than in architecture. In middle Europe the Byzantine and Saracenic tastes prevailed; in the north, the Gothic was then being developed.

The Roman power had been entirely destroyed in the West of Europe, Italy was divided into republics and principalities, of which the chief were Venice, Genoa, and Pisa, these being the earliest in fully establishing their liberty.

First Epoch.—The Pisans, who possessed considerable extent of coast, had in the eleventh century beaten the Saracens in Africa, Sardinia, Majorca, Minorca, and Sicily; and had thus acquired the treasures with which they commenced the erection of their cathedral in 1063. It was finished in 1092, about seven years after that of St. Mark at Venice had been consecrated. Schools of painting, sculpture, and architecture soon arose after this period, and the needs of the church found employment for the talent which they produced. It has been conjectured that Buschetto, who seems to have been a Greek, was the founder of the Italian, Gothic, or Byzantine school of architecture and sculpture at Pisa. The reputation of this school was raised to the greatest height by the appearance of Nicolo da Pisa, where he was born about 1205, the pride and glory of the thirteenth century, and the first who on its restoration gave dignity and importance to sculpture. That the Grecian fragments which the Pisans had acquired soon enabled Nicolo to discriminate between them and the style of Buschetto, is evident from some remains of his work in the Campo Santo. In 1225 he was employed at Bologna in decorating the sarcophagus of St. Dominic, in which his admiration and successful imitation of the antique shine forth. He built the basilica of St. Antonio at Padua, and the church of the Frari at Venice, remarkable for its classical ornament: he was afterwards engaged on the bas-reliefs of the pulpits at Pisa and Siena. He died at Pisa about 1278. Giovanni, the son of Nicolo, succeeded his father, to whom in some respects he was more than equal. He executed the sculptures of the Last Judgment on the façade of the cathedral of Orvieto, commonly attributed to his father Nicolo; he died in 1320, and was buried in the same tomb with his father in the Campo Santo, his own work. Their figures, especially those of their draped females, are elegant, and exhibit, says Flaxman, 'an originality of idea and a force of thought seldom met with when schools of art are in the habit of copying from each other.' The school of Pisa is not limited to the two just named. Arnolfo da Lapo (1232–1300) the brothers Agostino and Agnolo of Siena, and Andrea Pisano (1270–1345), all deserve to be recorded. Andrea executed in bronze the oldest gates of the baptistery at Florence, on which is represented the life of St. John the Baptist. This work is executed (from a general design by Giotto) with much grandeur and simplicity; but in his marble statues he is inferior to his master, Giovanni Pisano. Giovanni di Balduccio, scholar of Andrea, was of this epoch: his first works were at Milan, where in 1347 he executed the mausoleum of S. Pietro Martire. In the fourteenth century Giotto established a school distinguished by good

drawing, which prepared Florence for a perfect re-establishment of the art. To it belonged Orcagna (1315–76), a name ever to be remembered for his celebrated loggia at Florence: he was also eminent for his works in sculpture. A school at Siena, towards the end of this century, produced Jacopo della Quercia, whose principal works were at Bologna, Lucca, Florence, and especially Siena, where a fountain which he executed, at the cost of 2,200 scudi d'oro, was so admired that he acquired the name of Jacopo della Fonte. From his hand are the bas-reliefs in the façade of San Petronio at Bologna. The fifteenth century was a splendid era for the production of everything great and intelligent, and most especially for the art of sculpture. The love of liberty and knowledge seemed to animate the whole of the Italian republics; and as if the republic of the arts were not excluded from the common sentiment, no individual master seems so to have outstripped his rivals as to have impressed the art with his own particular style. (Perkins, *Tuscan Sculpture.*)

This period brings us to the *second epoch* of the Renaissance, the *Quattrocento*, at the beginning of which we find six great artists engaged in a competition for executing the bronze gates of the baptistery at Florence, in which, after a year's trial, Lorenzo Ghiberti bore away the palm from his rivals. Among these was Donatello (1383–1466), a Florentine, one of the most distinguished restorers of the art. 'Some of his works,' says Flaxman, 'both in bronze and marble, might be placed beside the best productions of ancient Greece without discredit.' His alto-rilievo of two singing boys in the Duomo at Florence is, in point of character, sentiment, drawing, and drapery, of extraordinary beauty. His marble statue of St. George standing upright, equally poised on both his legs, with his hands resting on the shield before him, so excited the admiration of Michael Angelo, that, after contemplating it in deep silence for a considerable length of time, he is said to have exclaimed suddenly, 'March.' Lorenzo Ghiberti (1381–1455) has immortalised himself in the work for which he bore away the prize from Donatello: from the eulogy bestowed on them by Michael Angelo, they bear the appellation of the 'Gates of Paradise.' Ghiberti made two sets of gates for the baptistery. This undertaking occupied forty-nine years of his life, from 1403 to 1452, and still, notwithstanding the criticism of Reynolds, remains one of the noblest monuments of modern art. The subjects are from the Old and New Testaments; and the complaint of Reynolds is, that 'the landscape and buildings occupy so large a portion of the compartment that the figures remained but secondary objects, entirely contrary to the principle of the ancients.' A cast of the 'Old Testament' gates is at the South Kensington Museum. Brunelleschi (1377–1444), the intimate friend of Donatello, better known by his high acquirements as an architect, was not less a sculptor of considerable eminence; at Florence, in the church of Sta. Maria Novella, is an admirable crucifix by him in wood. In 1470, Andrea Verrocchio was found amongst the first rank of sculptors in Florence; he was the master of Pietro Perugino and Leonardo da Vinci, and executed at Venice the famous figure of Bartolomeo Coleoni of Bergamo, on horseback. Antonio Begarelli was distinguished at Modena. We now come to Michael Angelo Buonarroti, whom we have once more [ARCHITECTURE; PAINTING] to introduce to the reader's notice as the most eminent of modern sculptors, as well as of architects and painters. The energetic works of this extraordinary man seem rather the result of inspiration than of genius, and with him is introduced

The *third epoch*, that of the *Cinquecento*, in which the perfect restoration of the art was accomplished. His own works, however, are, in spite of their great power, not free from manner; he was too ostentatious of anatomy, and his heads are usually too small for the limbs; though, in the case of his David, of which there is a cast at South Kensington, it is the body which is too small for the head and limbs. Many of Michael Angelo's works in sculpture may be seen in casts at the Crystal Palace. Vasari, the historian of the painters, sculptors, and architects, wrote the life of Michael Angelo while he was yet living, and thus justifies himself for so doing: 'Let none be surprised that I have here written the life of Michael Angelo, who is yet living. Indeed, it cannot be expected that he will ever die, and therefore it has appeared to me proper to do him this little honour; for when in common with other men his life shall pass away, he will be immortal in his immortal works, the fame of which, as long as the world lasts, will live with glory in the mouths of men and in their records, in contempt of envy and despite of death.' Michael Angelo was nobly descended, and at the early age of fifteen was patronised by Lorenzo de' Medici, who took him into his house, and continued his friend until his death in 1492. His career in sculpture was commenced by a sleeping Cupid, a Bacchus and young fawn, and a group of a Madonna sitting with the dead Christ on her knees, executed in 1499 at Rome, and his colossal David, made out of a single block, for the Piazza Granduca at Florence in 1502; works which raised him immediately above his contemporaries. It is not our purpose here to touch upon the productions of Michael Angelo in the other two arts which occupied a great portion of his time, and which it appears he afterwards regretted; for Condivi, his biographer, observes, 'Che mi rammenta udirlo dire che quando la (the basso-rilievo of the battle of Hercules with the Centaurs) vide, cognosce quanto torto egli abbia fatto alla natura a non seguitar prontamente l'arte della scultura.' Julius II., on being raised to the papal chair, employed Michael Angelo on a

mausoleum for himself, which it was intended to place under the centre of the dome of St. Peter's. It was projected on a most magnificent scale; but being subjected to many delays, and the pope dying, only one of its sides was completed, and thus was afterwards erected in the church of San Pietro in Vinculis by order of his nephew. In this monument is found the celebrated Moses and some other statues, partly executed by Michael Angelo, and partly by his pupil Raffaello da Monte Lupo: the monument was completed in 1550, it having been through various interruptions no less than forty years in progress. It is mortifying to know that a large portion of this artist's time was wasted at the quarries of Pietra Santa, owing to the misconduct of the underlings of Leo X. Cardinal Giuliano de' Medici, in 1523, engaged him on the sacristy and library of San Lorenzo. In the Capella dei Depositi, or sacristy, are the statues of Lorenzo and Giuliano de' Medici seated, and in Roman military habits: the former is conceived with a simplicity worthy of the highest era of Grecian art. The recumbent statues of Daybreak and Night, under the statue of Giuliano in the same chapel, 'are grand and mysterious: the characters and forms bespeak the same mighty hand and mind evident throughout the ceiling of the Sistine chapel and Last Judgment.' They are in casts at the Crystal Palace. He died on February 17, 1564, having nearly completed his ninetieth year. Flaxman, in his Tenth Lecture on Sculpture, closes his account of him thus: 'The character and works of Michael Angelo have been dwelt on at greater length, because, as his mental and bodily powers continued far beyond the usual date of human life, his diligence attained to so much greater perfection in the principles of art. Anatomy, the motion and perspective of the figure, the complication, grandeur, and harmony of his grouping, with the advantages and facility of execution in painting and sculpture, besides his mathematical and mechanical attainments in architecture and building, together with the many and prodigious works he accomplished, demonstrate how greatly he contributed to the restoration of art.' 'Michel,' says Ariosto, 'più che mortal, Angel' divino.'

After this epoch, or perhaps almost belonging to it, appeared Giovanni da Bologna, or John of Bologna (1524–1608), a Fleming so called for his fountain surmounted by Neptune, in that city. He was a sculptor of extraordinary merit, and eminent for his works in bronze and marble. His Venus coming from the Bath is delicate and graceful; and the group of the Rape of the Sabine women, in the grand piazza at Florence, is extremely well composed, and possesses a fine undulation of line. The Mercury also, springing from the Wind, is energetic and original. There are many small works extant by this artist. Benvenuto Cellini (1500–71), another follower of Michael Angelo, was one of the strangest and most eccentric characters that ever existed. He was chiefly employed as a goldsmith and sculptor in metals; but was frequently engaged on large figures and groups, of which the Perseus holding the head of Medusa in his left hand, in the Piazza Granduca at Florence, is a splendid example. Other real disciples of the great Tuscan master were Raffaello da Monte Lupo, his favourite pupil and assistant; Nicolo Tribolo, who executed some works for the façade of the cathedral at Bologna; and Vincenzo Danti. Of this time also are Baccio Bandinelli (1487–1562), a man of considerable talent, but greatly inferior to Michael Angelo, though he set himself up as a rival and competitor; Giovanni dell' Opera, a distinguished scholar of Bandinelli; Baccio da Monte Lupo, the father of Raffaello, who executed the wooden crucifix in the refectory of San Marco; Andrea Contucci, a clever and occasionally successful competitor of Michael Angelo, and founder of the school of Loretto; Francesco Rustici, a pupil of Leonardo da Vinci, but whose works evince a devotion to the style of Michael Angelo, and who introduced it into France; and Jacopo Tatti (1479–1570), commonly called Sansovino, who was the head of the Venetian school of sculpture. As an architect he was an artist of surprising talents, as is manifest from his works at Verona; his sculpture, however, is deficient in purity, though not in richness of composition. His principal pupils were Danese Cattaneo and Alessandro Vittoria. The principles of the school were diffused through Italy, and were equally to be seen in Lombardy and Naples: in the latter city the principal masters were Marliano da Nola and Girolamo Santa Croce. At Milan were Agostino Busti, and Guglielmo della Porta, whose reputation was raised by the statues executed by him on the tomb of Paul III. in St. Peter's. These have been esteemed as among the best examples of modern sculpture. Torregiano, who also belongs to this period, was, like Benvenuto Cellini, of a vagabond disposition, but a man of genius; he was invited over to England, where he wrought upon the tomb of Henry VII. at Westminster, for which he received the sum of 1,000*l*. He died, a prisoner of the Inquisition, at Seville, in 1522. In England, also, we had Giovanni da Padua in the following reign. Of native sculptors, William Austen, the artist of the Beauchamp tomb at Warwick, 1452, and a London founder, was not unworthy to rank with his Italian competitors in the fifteenth century.

Spain produced some celebrated sculptors in the sixteenth century, their first native artist being Berruguette, a pupil of Vasari and Michael Angelo. Berruguette's disciple, Paolo de Cespedes, the painter, of Cordova (1538–1608), is reputed the greatest sculptor that Spain ever produced.

It does not appear that Germany produced any sculptors of eminence before the seventeenth century. But in France, Jacques d'An-

goulême, who had been at Rome, where he had a competition even with Michael Angelo; Jean Gougeon (1510–72), who finished the Fountain of the Innocents at Paris in 1550, and is said to have been one of the victims in the massacre on St. Bartholomew's Day; Jean Cousin, whose works, though deficient in force and truth, yet exhibit much grace and delicacy; and Germain Pilon, whose detail is remarkable for its beauty—are names that entitle that country to a high rank among the nations of Europe, in which all the works of sculpture that were produced are so many testimonies of the influence which the genius of Michael Angelo exerted over the arts: though the French school is in its taste more directly allied to Parmigiano and Primaticcio.

At the commencement of the seventeenth century, Bernini, a native of Naples, born in 1598, raised himself to employment before unknown. Endowed with all the qualities necessary for becoming a great artist, and desirous of distinguishing himself by the foundation of a new school, he plunged into caprice and complexity, and, preferring effect to simplicity, effaced all traces of the style which from the time of Michael Angelo had prevailed in Europe. His draperies, founded on the paintings of the Bolognese school, his affected style, the violent expression in which he delighted, are the marks of an ambitious artist, whose only aim was to be striking. He deluged Italy with his works, and corrupted it with his taste till his death in 1680. The most celebrated contemporaries of Bernini were Algardi (1593-1654) and Duquesnoy (1594–1643), commonly called Il Fiammingo. The latter is much esteemed for his representations of youth, and particularly of infants. At Naples he executed a concert of cherubs, and two infants on a monument at Rome, which are his most admired works: the latter was particularly admired by Rubens, who says of it, 'Nature rather than art appears to have sculptured them, and the marble is softened into life.' Camille Rusconi in Italy succeeded to Bernini, and was the sculptor most in request at the beginning of the eighteenth century. His greatest works were those of San Giovanni in Laterano, where he was assisted by Monnot, Le Gros, Moratti, and Ottoni: he died in 1728. The further progress of sculpture seemed now impossible; in short, the art seemed to have departed, though men whose names are not worth recording, with all the pretensions of artists, still hovered about the scenes of its former glory. In England, Grinling Gibbons, a native of Rotterdam, was distinguished both as a statuary in bronze and a carver in wood; he died in 1721.

In France, Stefano della Bella, and Pietro Tacca, pupil of Giovanni da Bologna, occupy the interval up to the beginning of the reign of Louis XIV.—one extremely creditable to the French school, François and Michel Anguier being among the most distinguished. In the remaining period of that monarch's reign, the principal sculptors were François Girardon, born at Troyes in 1630, and Pierre Paul Puget, born at Marseilles in 1622, the latter of whom, from his fiery and energetic style, received the appellation of the Michael Angelo of France. These two were the head of the school of the succeeding sculptors of France, which comprised Desjardins, Antoine Coysevox, Pierre Francville, Pierre le Gros, Nicolas Coustou. To this school also belonged Étienne Falconet, celebrated for his writings, and for the equestrian statue he executed at St. Petersburg of the Czar Peter. The unfortunate Louis XVI., previous to the Revolution, was a great patron of sculpture, and had projected a collection of statues of the most eminent characters of the country. J. B. Pigalle, the sculptor of the day, had executed some of them before the dreadful period which stopped in France for a time all cultivation of the arts. The school of Pigalle was of considerable extent and influence, Mouchy, Bocquet, Moette, Chaudet, and Lebrun, being members of it, and continuing the art to within a generation of the present century. Of the recent sculptors of France, James Pradier, a Swiss (1792–1852), has acquired perhaps the greatest name. Contemporary, or nearly so, with these in Germany, were Rauchmüller of Vienna, A. von Schlüter at Berlin, N. Millich at Stockholm, and others; subsequent to whom are Ohnmacht, Sonnenschein, and Nahl of Strasburg, all sculptors of much reputation.

Our knowledge of Spanish sculptors is so limited, from their reputation not travelling away from their own country, and indeed being little known in Spain itself (except in Madrid and the chief cities, where the principal employment for them is the decoration of churches), that probably little interest would be created by an enumeration of them.

In England, up to a late period, the most celebrated sculptors were foreigners. C. G. Cibber, L. F. Roubiliac, and Peter Scheemackers had the sway; and monuments of their genius, especially of the second, are the pride of some of our churches.

The art, however, seemed to be near its dissolution, when Antonio Canova, in 1787, revived in Rome the purity without which it is worthless. This justly admired sculptor was born in 1757, at Possagno, a village amidst the Asolani hills, at the foot of the Venetian Alps. Pietro his father, and Pasino his grandfather, were sculptors, whose labours were chiefly confined to the churches of the district. Deprived of his father when only three years of age, he was indebted to his grandfather for the early instruction and employment of the chisel, by which he acquired great mechanical dexterity. Attracting the notice of the patrician Giovanni Faliero, he was by him placed with Torretto, one of the best Venetian sculptors of that day. Torretto soon afterwards died, and young Antonio then studied under Torretto's nephew, Ferrari. But he soon broke through the trammels of the art as it was then practised; and the rapidity of his progress

having induced his patron to find a more appropriate theatre for the exercise of his powers, the young artist was sent to Rome in December, 1780, soon after which time the Venetian government granted him a pension of 300 ducats for three years. At this period the fashionable sculptors of Rome were Agostino Penna, Pacili, Bracci, Sibilla, and others, whose productions are already forgotten: so that in the way of emulation Canova had little to excite his talents. Before the period had expired for which his pension was granted, the zeal of Volpato had been successful in procuring for him the commission to execute the monument of Clement XIV. (Ganganelli). Thus was afforded to the young sculptor an opportunity of exhibiting his powers to a public who were fortunately capable of appreciating his merit. Before the expiration of the eighteenth century he had produced an amazing quantity of works, at which time it was not the practice (one afterwards introduced by him) to employ inferior workmen to reduce the block to the last shape of the superficies. The enumeration of his works would occupy much more space than can be here assigned to them: they were often deficient in energy, but generally abounding in grace and elegance; and in his monumental sculpture there is a vast originality of invention, whilst it is free from extravagance. His females are voluptuous, but not offensively so; his execution of them is exquisite. In the monument executed in memory of the archduchess Christina of Austria, there is a pathos in the composition, the figures of which are linked together with the chain of nature in a manner worthy the divine Raphael himself. Canova died at Venice on October 13, 1822; and his remains were removed to his native place, in which he had erected, at his own expense, a splendid church. Albert Thorwaldsen (1770-1844), a contemporary of Canova, but much his junior, a native of Denmark, has by his great, though irregular and erratic, genius, raised himself to eminence throughout Europe as well as Rome and in his own country. His powers in basso-rilievo are great; but in his female figures he wants grace. Some distinguished names have also of late adorned the annals of the art in Germany: as Heinrich Dannesker of Stuttgardt (1758-1836); Ludwig Schwanthaler of Munich (1802-48); Christian Rauch of Berlin (1777-1857); and J. M. Wagner of Würzburg (1773-1858).

In England, the able sculptors John Bacon, Thomas Banks, and Joseph Nollekens, were followed by John Flaxman—a name honourable to the arts of this country. Intense feeling and simplicity characterise all his works; and in epic sculpture he perhaps surpassed Canova. He was born at York in 1755, and died in 1826. The lectures which he delivered as professor of sculpture at the Royal Academy have been published. (*Lectures on Sculpture, &c.*, with fifty-two plates, 2nd edition, 1838.) Sculpture has made great progress in England since the days of Flaxman. Not to mention living men, a very respectable array of names may be selected from the list of deceased sculptors: Sir Francis Chantrey (1782-1841); Sir Richard Westmacott (1775-1856); J. C. F. Rossi (1762-1839); Samuel Joseph (1791-1850); Richard Wyatt (1795-1850); John Hogan (1802-58); Benjamin Wyon (1802-58); M. L. Watson (1804-47); John Gibson (1780-1866), and Matthew Cotes Wyatt (1778-1862), the sculptor of the equestrian bronzes of George III. in Cockspur Street and of the Duke of Wellington at Hyde Park Corner, the last the most absurdly placed monument in Europe. For a general history of modern sculpture the reader is referred to the illustrated work of Count Cicognara,—'The History of Sculpture from its rise in Italy to the century of Canova, to serve as a continuation of the works of Winckelmann and of D'Agincourt.'

Sculpture, Practice of. The work of the sculptor is generally limited to modelling in clay; from this model a plaster cast is taken, and from the cast the marble figure is copied by carvers aided by the pointing machine.

A model as large as the intended figure or group is first made in clay. It is placed on a stand or banker with revolving top called the sculptor's easel; and the general form is got out with the hand and fingers, small box-wood or wire tools being made use of to shape the parts that the fingers cannot reach. The clay is kept moist, to prevent its shrinking, till the model is completed. The model is then moulded in plaster of Paris, before it begins to dry, whence a matrix is formed, into which plaster is introduced; and the matrix being broken away from it, the model in clay is thus transferred into one of plaster. This becomes the standard from which the artist takes all the measurements for the figure he is about to execute. The block of marble and the model being now placed on stands, with a graduated rod, which moves on a frame perpendicular to it, and has a point attached to it which can be made to advance and recede at pleasure, certain prominent points are selected and marked in the model, and their distance measured on the frame longitudinally and vertically, and also the distance that the point on the rod is advanced or receded in order to touch a given point. This being found on the outside of the rough block, the particular point is drilled down to as great a distance as was measured in the model. This operation being repeated for a great number of points, the surface is worked away to all the several points found as above, till at last it assumes the general form of the model. As the sculptor approaches the surface which is to be left when finished, more caution and finer tools become necessary, till at length it is brought into a state for his finishing touches. This purely mechanical process of bringing the shapeless block into something like the form which it is ultimately to bear is performed by workmen, thus effecting a great saving of the artist's labour and time [Modelling; Wax Modelling.]

Scupper (Span. escupir). A hole in a ship's deck or side to carry off the rain or water shipped. Means should be at hand to plug scuppers when the ship rolls them below the surface.

Scurvy (Low Lat. scorbutus). This disease, once so common in our navy, is now of very rare occurrence. It generally appears to be connected with debilitating causes, and especially with unwholesome food, want of exercise, cold and moisture. It begins with indolence, sallow looks, and loss of strength and spirits; the gums become spongy, the teeth loose, the breath fetid; livid eruptions appear on different parts of the body, known as *petechiæ* and *vibices*, and at length the patient sinks under general emaciation, diarrhœa, and hæmorrhages. In the prevention and cure of this disease, much is effected by attention to diet and cleanliness. Fresh vegetables, farinaceous substances, and brisk fermented liquors, good air, and due exercise, are among the principal remedial means. Acids, and especially lemon juice, have been much extolled.

Scutage (Lat. scutum, *a shield*). In Feudal Law, scutage was a commutation for personal service in foreign wars, paid by military tenants: made general in England, under Henry II. in 1159. [Escuage.]

Scutate (Lat. scutatus, from scutum, *a shield*). In Zoology, when a surface is protected by large scales.

Scutellum (Lat. scutum). In Botany, a term used by Gærtner to denote the small cotyledon on the outside of the embryo of wheat, inserted a little lower down than the other more perfect cotyledon, which is pressed close to the albumen. Also the shields of some kinds of Lichens, as *Parmelia*.

Scutibranchians (Lat. scutum; branchiæ, *gills*). A name given by Cuvier to an order of hermaphrodite Gastropodous Molluscs, including those which have the gills covered with a shell in the form of a shield.

Scutigers (Lat. scutum; gero, *I carry*). The name of a genus of unequal-legged Chilopodous Myriapods, which frequent houses and out-buildings in the South of Europe, and prey upon insects, wood-lice, and other small creatures.

Scutipeds (Lat. scutum, and pes, *a foot*). The name given by Scopoli to one of the divisions in his binary system of ornithology, including those birds which have the anterior part of the leg covered with segments of unequal horny rings terminating on each side in a groove.

Scuttle (A.-Sax. scyttel, Span. escotilla, Fr. écoutille). An easily closed opening in the ship's side or deck to admit light or air, or for communication.

To scuttle the decks, implies to cut holes to let the water down from them into the hold, as in the case of fire.

To scuttle a vessel, is to cut a hole in her for the purpose of sinking her.

Scuttle Butt. A cask of water with a large hole in it placed for use in a ship.

Scutum (Lat.). The shield of the Roman heavy-armed legionaries: made of wood, defended with plates of iron, and covered with leather. It was either oval or of semi-cylindrical shape. In the centre was a boss of brass or iron, projecting from the shield. From this word is derived the modern term Esquire.

Scylla (Gr. Σκύλλα). In Greek Mythology, a daughter of Nisus, king of Megara. When Minos came from Crete to take vengeance for the death of his son Androgeos, his efforts to take the city were fruitless as long as the purple lock on the head of Nisus remained unshorn. Urged by her love for Minos, Scylla cut off the fatal lock, and with it destroyed the life of her father and the safety of the city. According to one version, Minos tied Scylla to the stern of his ship and drowned her; but another tale says that she was changed into a fish which Nisus, transformed into an eagle, constantly pursued. The myth was localised in the names of the port of Nisæa and the promontory Scyllæum.

The *Odyssey* (xii. 73, &c.) speaks of another Scylla, a daughter of Cratæis, as a monster with twelve feet, six necks, and six mouths, each containing three rows of teeth. This being haunted a rock on the Italian coast; a neighbouring rock being tenanted by Charybdis, who thrice every day swallowed the waters of the sea, and thrice threw them up again. Like Medusa, Scylla is represented in some legends as having been beautiful, and as having been changed into a monster through the jealousy of Circe or Amphitrite.

Scyphus (Lat.; Gr. σκύφος, *a cup*). In Botany, a cup or coronet, such as occurs in the *Narcissus* and allied plants. Also, in Lichens, a cup-like dilatation of the podetium, bearing shields upon its margin.

Scytale (Gr. σκυτάλη). An instrument used by the Lacedæmonians for the conveyance of secret instructions to their commanders. The construction of it was as follows: When a general was sent out, a black rod was given him, while another of exactly similar dimensions was preserved at home. When instructions were to be sent out, a strip of parchment was wrapped round the rod and on the folds the orders were written; these he read by unrolling the parchmen with the rod in his possession.

Scythian Lamb. One of the names of the fern called by botanists *Cibotium Barometz*.

Sea (for the origin of the word, see Soul). The expression employed by sailors to describe the condition of the waters they are traversing. A *long sea* is one in which the crests of successive waves are distant from each other, and in which the effect upon the ship is a heavy rolling motion. A *short sea*, on the other hand, is when the waves are frequent, irregular, and crowned by foam. They produce a pitching motion. A *cross sea*, the most irregular, is when a change of wind or a current drives one succession of waves in a direction different from that of another series resulting from the swell caused by a former storm.

Sea. In Geography. [Ocean.]

Sea and River Defences. The walls, embankments, or other constructions intended to protect coasts and river banks from the destructive action of the waves, or from the erosive action of flowing water. In some countries, such as Holland, where a large part of the land is below the level of the sea, disastrous inundations are only to be prevented by a system of dykes or sea embankments which shall be sufficiently heavy and sufficiently tight to prevent the entrance of the water, and which shall be faced with materials sufficiently strong to resist the force of the sea. Rivers flowing through alluvial districts, such as the Ganges or Indus, are apt to wander about, and require to have their channels fixed, which is best done by brushwood, the friction of which upon the water arrests the velocity of the flow in that part, and which soon consequently becomes silted up.

There is much difference of opinion among engineers as to whether sea-walls intended to encounter the shock of the waves should be vertical, from the face of which the waves will be reflected, or inclined like a beach, so that the waves will expend their force upon it in friction and be broken up. Much manifestly depends upon the depth and nature of the bottom. If a vertical wall deflects a wave, it will deflect it downwards as well as upwards, and if the bottom is weak and not distant, it may be undermined by the deflected water, and the wall may tumble down. In cases, however, where these objections do not exist, the vertical wall appears to be the best, since, instead of exhausting upon itself the force of the waves, it enables the waves to take a new direction without having been robbed of much of their momentum which will be finally expended on the sea-shore. In Holland many of the dykes have a long fore shore to break up the waves and dissipate their energy before they reach the main structure, and this provision is generally adopted on the Essex coast and elsewhere. The best material for the heart or body of a sea-wall is stiff clay, but even this material requires to be carefully packed to prevent percolation. In Essex the clay is dug from the fore shore in spits, and packed into a sea-wall by an operation termed *flood flanking*. The spits are delivered by the barrow men to the packers, who, taking each spit on a pitchfork, strike it forcibly into its place. The crevices produced by the shrinkage of the spits in drying are filled with mud, which is called *sludging*. Peat or bog is sometimes used for sea-walls, and it is fibrous and tough, but light, and requires to be weighted with stone. Gravel is valuable for the formation of an artificial beach at the foot of the wall, and which also serves as a road. Usually sea-walls are faced with stone, and by spreading gravel over this facing the small stones insinuate themselves and wedge the large stones together. If the embankment is made with a great slope seaward, it will sometimes be sufficient to cover the slope with gravel so as to form an artificial beach.

The Roman embankments formed on the coasts of Essex and Lincolnshire, and also on the lower parts of the Thames, consist of steep mounds of earth defended by rows of piles, the spaces between the rows, or *rooms*, as they are called, being filled up with chalk. Modern embankments consist of three parts: First, the *main* bank, about 20 feet wide at top, with a rise of tide of 10 feet, and formed with a slope in the lower portion of 5 to 1, and in the upper portion of 4 to 1; secondly, the *outburst* bank, 5 feet high and 8 feet wide at top, placed on top of the foregoing, formed with a slope of 1½ to 1; and thirdly, the *swash* bank, 2½ feet high and 2½ feet wide at top and 8 feet wide at bottom, placed on top of the outburst, and which is supposed to arrest only the tops of the waves. The embankments should be faced with stone laid on a solid facing of clay in all cases where the exposure to the waves is great; but in other cases it will be sufficient to coat that portion above ordinary spring tides with gravel and clay, and to cultivate upon it couch-grass, ray-grass, and lucerne. If the materials are too weak to stand without injury until these grasses grow, the surface should be turfed over. In Holland some of the dykes are thatched on the sea side, and some are made with a timber framework, within which the stone facing is fitted. At some distance from the embankment on the inner side a ditch is dug to carry off any infiltration.

On some coasts groynes, or walls of timber or stone carried down into the sea, are employed to arrest the movement of the shingle coastwise, and thus to create a natural embankment. Important sea-walls and piers are sometimes formed of béton or concrete, formed into square blocks and then used as stones. Sometimes also the béton is lowered while still soft in a bucket with tilting bottom into the water, and is then let out on the surface of the ground, whereby an artificial rock is built up.

The foundation for river walls or other constructions on the banks of rivers in alluvial countries, such as Bengal and the Punjaub, require to be formed with wells according to the native practice; or screw piles or iron cylinders may be substituted. For further information respecting sea and river defences, the reader may consult Lamblardie, *Sur les Côtes de la Normandie*; Syanzius, *Cours de Construction*; Minard, *Cours des Travaux Hydrauliques à la Mer*; the *Annales des Ponts et Chaussées*, passim; Romano, *Sulle Lagune di Venezia*; Galileo, Frisi, Guglielmini, &c., *Tracts upon Hydraulics*; Page's *Report on the Drainage of the Fenland*; Coode *On the Portland Breakwater*; the *Reports on the Formation of Harbours of Refuge*, presented to the House of Commons; and the Dutch and German works upon the defence of the sea-shores, and upon the preservation of the bank of the Rhine and other rivers, in those countries.

Sea-anemone. The name of a highly organised Polype of the genus *Actinia*.

Sea-bear. A vulgar epithet applied inaccurately to several large species of seals. The use of such words is much to be deprecated.

Sea-boat. A term applied by seamen to a vessel, as respects her qualities in bad weather.

Sea-devil. The seaman's name of a large cartilaginous fish of the Ray tribe, the type of the genus *Cephaloptera*, Cuvier; also applied to the angler (*Lophius piscatorius*, Linn.).

Sea-girdles. The common name for the alga *Laminaria digitata*.

Sea-hare. [Aplysia.]

Sea-holly. The *Eryngium maritimum* of botanists, a harsh spiny-leaved sea-side plant.

Sea-horse. The term is most correctly given to a small Lophobranchian fish found in the Mediterranean, the *Hippocampus*. It is also sometimes applied to the Walrus (*Trichechus rosmarus*) a large phocine mammal, found in the Arctic Ocean.

Sea-jellies. A vulgar name for the animals allied to the Medusa.

Sea-kale. [Crambe.]

Sea-mew. A name for the gull, derived from the French *mouette*. [Larus.]

Sea-otter. The *Enhydris inunguis*, a genus of Lutrine Carnivora, the fur of which is much sought after, and whose toes are webbed together to a greater extent than in the true otters. [Lutra.]

Sea-pink. One of the names of the Thrift, *Armeria vulgaris*.

Sea-serpent. This word, with the common prefix *Great*, represents the idea of a surface-swimming, air-breathing, marine animal, of a snake-like shape and undulatory motion, variously reported by alleged eye-witnesses as being from 100 to 600 feet in length; and, by most, as having a *mane*. The best attested instance is that which was said by several independent witnesses to have been seen off the island of Stronsa, in the Orkneys, in 1808. Their reports on affidavit before the local authorities are embodied in the paper by Dr. Barclay in the first volume of the *Wernerian Transactions of Edinburgh*. In this paper that anatomist gave an account of the vertebræ of the supposed animal which had been cast upon the rocky shore of the island during a great storm, shortly after its appearance off the coast had alarmed the fishermen. Two of the vertebræ had been fortunately sent to the museum of the London College of Surgeons; their true nature was recognised by Owen, and described in his catalogue of the Osteology in the Museum (4to vol. i. p. 98, 1853) as vertebræ of the great basking shark (*Selache maxima*, Cuv.). The appearance, interpreted as the sea-serpent, had been caused by the alternate rise and fall, on the surface of the sea, of the dorsal fins of two individuals, probably male and female, of the basking shark, closely following each other. Both had been driven ashore by the storm; and, being afterwards discovered in a decomposed state, their back-bones were put together lengthwise, as of one animal, by the fishermen, making a total of upwards of sixty feet in length.

Many and divers are the phenomena at sea which recall the preconceived notion of the great sea-serpent; and, viewed in that frame of mind, a distance too great for accurate observation, leave a conviction of the marvel which is testified to in good faith. Whenever the monster has been closely approached or captured, it has turned out to be other than was supposed. Captain Sir James C. Ross, in his antarctic voyage, ordered out a boat to approach and if possible kill and capture what seemed to him, his officers, and crew, to be a veritable sea-serpent. It proved to be the great sea-elephant, *Phoca* (*Cystophora*) *proboscideus*, nearly thirty feet in length, but leaving a strong wake of more than twice that length through the powerful action of the tail-propeller. In other instances, the supposed sea-serpent has proved to be a succession of grampuses or porpoises tumbling in line, one after another, and deceiving the eye as a continuous undulatory body, when first seen at a distance; or it has been found to be a log or spar covered with barnacles and sea-weed, which, lifted by the waves and falling, represented the mane of the preconceived monster. Professor Owen's letter in the *Times* of May 10, 1849, 'On the sea-serpent alleged to have been seen by Capt. McQuhae, of H.M.S. Dædalus,' gave a blow to the animal from which it has never recovered. Since the publication of his recommendation in the *Admiralty Manual of Scientific Enquiry* (*Zoology*), the accounts of the true causes of the appearance have multiplied, and the newspaper paragraphs of the fabulous cause have grown scarce.

'When an object is seen afloat, attracting notice by its magnitude or other peculiarity, and is not captured, its nearest approach to the ship, its mode, course, and rate of progression, and the parts actually recognisable, should be noted at the time with the utmost accuracy. If practicable, a boat should be put off for close observation. If the observer has not the zoological knowledge, or the opportunity for exact inspection, requisite for determining the species from the phenomena, he should abstain from giving the object any special name. Supposing it to be an animal, a shot fired, if it do not hit, may so alarm the creature as to cause some sudden movement which may reveal more of its true nature' (p. 50). This recommendation should be followed in all cases of phenomena simulating the great krakens and sea-serpents.

Nevertheless, sea-serpents do exist: they even abound in some localities in the tropics; they belong to the genus *Hydrus* or *Hydrophis*, and are distinguished from land serpents by their compressed tail, which thus becomes a swimming organ. The species are commonly from two feet to four feet in length; rarely, approaching to ten feet. There is no à priori reason why such sea-serpents should not rival or surpass the whale in length: but, owing to the long and large lung-like air-bladder which, as serpents, they would possess, they would usually float some time after death: and it is hardly

conceivable that some of the vertebræ should not have been met with on the coasts of America or Norway, where (according to Pontoppidian and Hans Egede) the monster has been most commonly witnessed, if it had ever existed as a species, represented by the numerous individuals of countless successive generations since creation. The fishes which, after *selache*, have been found to raise the notion of the sea-serpent, are those of the tænioid family or *riband-fishes*; of which the species called *Gymnetrus Banksii* has furnished specimens of nearly 20 feet in length, cast ashore on the coast of Durham and Northumberland. The idea that some lingering representatives of Mesozoic sea-reptiles (*Ichthyosaurus, Plesiosaurus*) may have originated the notion of the great sea-serpent, has been entertained by some who were ignorant of the laws of palæontology.

Sea-sickness. Nausea and retching, which attack most persons on first going to sea; sometimes continuing only a day or two, but often lasting the whole of a long voyage. In some persons its violence is prevented by small doses of opium or by soda water, or saline draughts in the effervescent state. Liniments and plaisters containing opium applied to the pit of the stomach have also been recommended, as mitigating, or even preventing, this most annoying malady. The violence of the attacks not only varies in different individuals at different times, but the same person who escapes in one voyage may suffer severely in another. Dr. John Chapman, who has recently proposed the application of ice to the back as a remedy for this malady, holds that the proximate cause of sea-sickness consists in an undue amount of blood in the nervous centres along the back, and especially in the segments of the spinal cord related to the stomach, and the muscles concerned in vomiting. (*Functional Diseases of the Stomach*, part i.; *Sea-sickness, its Nature and Treatment*, London, Trübner, 1864.) This excess of blood can, he maintains, be reduced by the application of ice, which is a direct sedative to the spinal cord, if placed immediately over it, by lessening its functional and especially its automatic or excito-motor power. This remedy, which Dr. Chapman states has been applied with singular success in cases of sea-sickness, he believes to be likewise applicable in other diseases which have hitherto more or less baffled medical treatment.

Sea-thongs. One of the names for the British alga *Himanthalia lorea*.

Sea-trumpet. The common name for the alga *Ecklonia buccinalis*.

Sea-unicorn. The colloquial name for the narwhal (*Monoceros*), a large species of true Cetacean, in which one of the canine teeth in the upper jaw is extraordinarily developed, and forms a spear-like bone of a spiral form used by the narwhal as a powerful weapon.

Sea-urchin. The name generally applied to the different species of *Echinus*.

Sea-weeds. [ALGÆ.]

Sea-wolf. The *Anarrhichas lupus*, a fish, is often so called in reference to its powerful teeth and its destructive carnassial habits.

Sea-wrack. The sea-weed thrown up by the tide, and collected by farmers and others for the purpose of manuring cultivated land. The name is also applied to *Zostera marina*.

Seal (Fr. sceau, or scel; Lat. sigillum, dim. of signum). In Gem Sculpture, a stamp cut or sunk on stone, capable of yielding an impression to any soft substance. When a gem is selected for cutting, it is put into the hands of the lapidary to reduce it to shape and smoothness. It is then fixed with mastic to a piece of wood to serve as a handle, and the subject is sketched upon it with a copper point or a diamond. The tool is a lathe somewhat resembling a turning lathe, and into the end of the spindle points, knobs, or circles can be inserted. The gem is then applied to the end of one of these tools, according to the nature of the cutting required, wetted with diamond-dust and olive oil, and by frequent working the subject is wrought. Frequent impressions are of course taken during the progress, to show the excesses or defects. These, however, are not necessary in working cameos, because the prominences are obvious to the eye. The tools are soft iron or copper; and the powder of the ruby, or other hard stones, is often substituted for diamond powder.

SEAL (A.-Sax. seol). In Zoology, the English name for a genus of Marine Carnivorous Mammiferous Quadrupeds, otherwise called *Phocidæ*. The variety of seals is very great, and they are found in great numbers in the seas round Spitzbergen, and on the coasts of Labrador and Newfoundland. The species (*Phoca vitulina*) which frequents the British shores is well known, and has been repeatedly described. Seals are principally hunted for their oil and skins. When taken in the spring of the year, at which time they are fattest, a full-grown seal will yield from eight to twelve gallons of oil, and a small one from four to five gallons. The oil, when extracted before putrefaction has commenced, is beautifully transparent, free from smell, and not unpleasant in its taste. The skin, when tanned, is extensively employed in the making of shoes; and when dressed with the hair on, serves for the covering of trunks, &c. The seals of the southern hemisphere have the fins better developed and more serviceable for motion on land than those of the northern hemisphere. [FISHERIES.]

Seal, Great. All charters, commissions, grants of land, franchise, liberties, &c., letters patent and letters close, of the king, pass the great seal. The course formerly was, that a grant, or letters patent, passed by bill; which was prepared by the attorney or solicitor general under warrant from the king. It was then subscribed at foot with the sign manual, and sealed with the privy signet. In this stage it was next, in some cases, taken directly to pass the great seal; in other cases, an

extract of the bill was taken to the keeper of the privy seal, who made out a writ or warrant thereupon to the chancery, where it passed the great seal. Thus the sign manual was a warrant to the privy seal, and that to the great seal. There were, however, some grants which only passed through certain offices, as the Admiralty or Treasury, under the sign manual, requiring neither privy nor great seal. By a recent act, however (stat. 14 & 15 Vict. c. 82), the practice of passing instruments under the great seal was simplified, and power given to the Lord Chancellor to make regulations with respect thereto. The custody of the great seal is now always entrusted to the Lord High Chancellor of Great Britain, that great officer being constituted by the mere delivery of the great seal into his hands, without patent or other formality.

In earlier times the offices of Lord Chancellor and of Lord Keeper of the great seal were occasionally distinct, but by 5 Eliz. c. 18 the keeper of the great seal has the same place and jurisdiction as the Lord Chancellor; since that statute, therefore, these offices cannot exist at the same time in different persons. The office of Lord Keeper has occasionally been revived in more recent times; the last Lord Keeper was Sir Robert (afterwards Lord) Henley, in 1757. When, as sometimes happens, the office of Lord Chancellor is put into commission, the great seal is entrusted to the chief commissioner. The seals of Scotland and Ireland are still in use for some purposes.

Seal, Privy. [SEAL, GREAT.] Some instruments of minor consequence pass the privy seal only. The keeper of the seal is now an officer of state, with the title of Lord Privy Seal. By 14 & 15 Vict. c. 82, the offices of clerks of the signet and privy seal were abolished.

Sealing-wax. The wax used for sealing letters, legal instruments, &c. The best *red* sealing-wax is made by melting in a very gentle heat 48 parts of shell-lac with 19 of Venice turpentine and 1 of Peruvian balsam; 32 parts of the finest cinnabar, thoroughly levigated, are then stirred in, and the whole well mixed. When it has cooled down, it is either rolled into sticks, or shaped in brass moulds. The best *black* sealing-wax is a mixture of 60 parts of shell-lac and 30 of ivory black: it may be perfumed with a little Peru balsam or styrax. The earliest application of sealing-wax to its present use seems to have been made about the year 1553. The first printed account of it is said by Berzelius to have appeared in 1563. The great seals applied in tin boxes to certain legal documents are made of a mixture of 15 parts Venice turpentine, 5 of olive oil, and 8 of wax melted together, and coloured with red lead.

Seaman. A man brought up to the sea, and capable of discharging the duties of that life. A complete seaman is called an *able seaman*, and is rated A.B.; one less competent, an *ordinary seaman*; and a man fresh from the shore, a *landsman* or ordinary seaman of the second class. The conditions upon which seamen are to be hired for merchant vessels, with their privileges and obligations, are regulated by the Merchant Shipping Act of 1854, &c. Wages are contingent on the success of the voyage; loss of a ship or capture by an enemy consequently exonerates the owners from liability for the wages of their seamen. For the Royal Navy the engagement of seamen takes place under the provisions of the Mutiny Act for the time being. The reader will find in the *Com. Dict.* full particulars respecting the enrolment, wages, and in short all the statistics of seamen.

Seams (Ger. saum). In a ship, the spaces between the edges of planks: these are caulked with oakum, and then covered with pitch.

SEAMS. In Geology, thin layers which separate thicker strata. Beds of coal are sometimes called *seams*.

Search, Right of, or more accurately of **Visit and Search.** In International Law, in time of war, right of search is defined to be the right of a belligerent to 'visit, to search, and to detain for search' every vessel, not being a ship of war, which he meets with on the ocean. It can be exercised only by a vessel commissioned by the authority of the state to which it belongs, whether man-of-war or privateer. The right of search in time of peace, to ascertain the nationality of a vessel, with a view to detecting piracy and slave trading, has been the subject of much controversy. (Phillimore, *International Law*, part x. ch. iii.)

Search Warrant. In Law, a warrant granted by a justice of the peace, to search for goods stolen, or respecting which other offences have been committed. The warrant is granted on the oath of a credible witness, that he has 'reasonable cause to suspect' the goods to be in the possession and on the premises of a certain individual (24 & 25 Vict. c. 96).

Seasons (Fr. saisons). The four quarters of the year—spring, summer, autumn, winter. The seasons are considered as beginning respectively when the sun enters the signs Aries, Cancer, Libra, and Capricorn; so that the *spring* season commences about the 21st of March, *summer* about the 22nd of June, *autumn* about the 23rd of September, and *winter* about the 23rd of December.

Sebaceous Glands (Lat. sebaceus, from sebum, *suet*). Small cuticular glands which secrete a greasy matter, serving to protect and soften the skin and cuticle.

Sebacic Acid (Lat. sebum). One of the acids produced during the destructive distillation of fat.

Sebestens. The dried fruits of *Cordia Myxa* and *C. latifolia*, which have long been used as a medicine in India.

Secale (Lat.). A genus of cereal grasses, to which belongs the Rye, *S. cereale*, a cornplant commonly cultivated for its nutritious grain, the flour of which forms an inferior kind

of bread. According to Karl Koch, Rye is found wild on the mountains of the Crimea, at an elevation of from 5,000 to 6,000 feet, its ears in such places being not more than from one to two and a half inches long. In this country it is the most limited of our corn crops.

The name of *S. cornutum* is sometimes given to Ergot of Rye, which is a black horn-like spur, into which the seeds or grains are changed as the result of disease. The same thing occurs in other grasses. In rye some of these spurs are as much as an inch in length, whilst in *Lolium* or Raygrass they seldom attain to half this size, and in smaller grasses the ergot is in proportion to the size of the seed. The Ergot of Rye has long been known as prevailing to a considerable extent in countries where rye is grown for bread, and some dreadful maladies are reported to have arisen where it has been ground with flour. Where it occurs amongst pasture grasses, its more immediate effect upon gravid animals appears to be the procuring of abortion; and as one of the commoner grasses, in which it occurs probably to a greater extent than in any other of our native species, is the *Lolium perenne*, which is always found to be largely mixed with all good pastures, it becomes a matter of importance to look well to a meadow in autumn before turning in cows, as there is too much reason to believe that abortion is somewhat frequent from a want of care in this respect. The quantity of ergot in almost any native species of grass growing in low damp meadows is quite astonishing; and even uplands are not without a considerable proportion if they have sufficient altitude to attract atmospheric vapours. Where and when it prevails there is much evidence to show that it is not advisable to depasture; but in cases of necessity the skimming over the bents with the scythe before the admission of cattle is a plan which might obviously be adopted with advantage. [ERGOT, ERGOTISM.]

Secant (Lat. seco, *I cut*). In Geometry, any right line which cuts a figure. A tangent is the limiting position of a secant when two points of intersection coincide. In Trigonometry, the *secant of an arc* is the line drawn from the centre of the circle through one of the extremities of the arc to meet the tangent at the other extremity. The *secant of an angle* is the reciprocal of the cosine.

Seceders. [BURGHERS.]

Secession (Lat. secessio, *a going aside*). In Politics, the act of a portion of a community (or, in common parlance, of a party in deliberative assemblies) who separate from connection with the remainder, and endeavour to form a body apart. The term had its first application in the instance of the alleged secession of the Roman plebeians to the Mons Sacer, as a protest against the usurpation of the patricians.

In modern times, it has come into popular use from a great recent example—the act of the so-called *Confederate* States in seceding from the American Union. The main argument used in favour of this proceeding was, that the constitution of 1787, while declaring that 'Each state retains its sovereignty, freedom, and independence,' contains no provision directly qualifying this doctrine by maintaining the inviolability of the Union; and that, consequently, the right of secession is implied in the term *sovereignty*; while the previous articles of confederation, superseded by the constitution, had contained the words 'the union shall be perpetual,' which it was reasonable to infer had been purposely abandoned. The answer ordinarily made was that the Union was in the nature of a league, implying mutual abandonment of rights in their very nature inconsistent with the existence of such union: and that there was no more occasion to prohibit, expressly, the repudiation by a state of the compact thus made, than to prohibit the *secession* of a county, a township, or an individual. See the argument on the Confederate side as stated by Mr. Spence, in his work on the American Union, 1862.

Sechium (a word coined from Gr. σηκίζω, *to fatten in a fold*). A genus of *Cucurbitaceæ*, represented by *S. edule*, the Chocho, commonly cultivated in the West Indian islands for the sake of its fruit, which is reckoned extremely wholesome, and is commonly used as an article of food by all classes. It has also the reputation of being a very fattening food for hogs and other animals. It is a climbing plant, with smooth stems rising from a very large fleshy root, which sometimes weighs as much as twenty pounds, and resembles a yam both in appearance and in its eatable qualities when cooked. The fruit is about four inches in length, oblong, between fleshy and succulent, sometimes furnished with small innocuous prickles, and either green or cream-coloured. The plant has been introduced into Madeira and other Atlantic islands, and from this source its fruits, called Chayotes, are sometimes sent to this country in a fresh state, and sold in Covent Garden Market.

Secle (Lat. sæculum, *an age*). In Chronology, a division of time. There were various secles; as the heroic secle, which consisted of 77 years [ROMULUS], the national secle, &c. [SOTHIAC PERIOD; TABULATION OF CHRONOLOGY.]

Second (Lat. secundus, *that which follows*, denoting the closest sequence). In Music, a musical interval; being the difference between any note and the next nearest, whether above or below it. It may be either major or minor. [MUSIC.]

SECOND. In the sexagesimal Arithmetic, the 60th part of a minute, or *prime*. Thus a degree of a circle, and an hour of time, are each divided into 60 minutes, and each minute into 60 seconds. In the old treatises on astronomy, the seconds are sometimes denominated *second minutes* (minutæ secundæ); while the minutes being the first divisions of the unit, are the *primes* (minutæ primæ). Following out the analogy, the sixtieth part of a second was called a *third*; but this term is not found in modern works. It was formerly usual to denote minutes

and seconds, both of time and arc, by the characters ′ and ″; but these are now generally, used only to indicate minutes and seconds of arc, those of time being indicated respectively by the abbreviations *m.* and *s.*

Second Coat. In Architecture, either the finishing coat, as in laid and set, or in rendered and set; or it is the floating when the plaster is roughed in, floated, and set for paper.

Second Sight (called in Gaelic taischitaraugh; from taisch, *an unreal* or *shadowy appearance*). A well-known Highland superstition. In all ages the idea has prevailed that persons endowed with the power of divination not only foretold by instinct, but had sometimes an actual and mysterious vision of distant or future events; as in the lines of Lucan, which describe the presages before the battle of Pharsalia:—

> Euganeo, si vera fides memorantibus, augur
> Colle sedens . . . .
> Venit summa dies, geritur res maxima, dixit:
> Impia concurrunt Pompeii et Cæsaris arma.

But the peculiarity of the Highland superstition seems to consist in this, that persons were supposed to be endowed with the faculty who were in no other respect feared or reverenced for their supernatural powers; it was regarded as a mere natural power, like superior sharpness of sight or hearing. The inhabitants of the Western Islands were thought to be peculiarly gifted with it. It could not be exerted at pleasure; the power came on the seer involuntarily, and often to his extreme terror and suffering. Nevertheless, certain rules were in fashion for the interpretation of the visions; such, for instance, as that mentioned by Sir W. Scott, that if a seer saw a figure with its back to him, and if on altering the position of his own plaid the figure appeared with its plaid similarly arranged, the vision regarded the seer himself. (See the superstition of the Bodach Glas, Scott's *Waverley*.) Martin, in his *Description of the Western Islands,* seems to have brought this superstition into notice in England. It is well known how Johnson undertook the defence of it, in his *Journey to the Western Islands*; but, in despite of evidence which neither Bacon, Boyle, nor Johnson were able to resist, the *taisch*, with all its visionary properties, seems to be now universally abandoned to the use of poetry. Campbell's beautiful poem of *Lochiel* will at once occur to the recollection of every reader. It is described by Collins in his ode on the *Superstitions of the Highlands.* But the classical bard of the second sight is Sir Walter Scott. (See especially his noble ballad *Lord Ronald*, the *Lady of the Lake,* the character of Allan Macaulay in the *Legend of Montrose,* &c.) Of belief in second sight at the present day, Mr. Logan, in his *Scottish Gael,* only says, 'It is not so prevalent as formerly.' (Vol. ii. 340.)

Secondaries. In Astronomy, this term denotes the satellites with regard to planets and the planets with regard to the sun, to distinguish them from their respective primaries. Thus, the moon is a secondary body with regard to the earth; the earth with regard to the sun, &c. [PLANET; SATELLITE.]

Secondary Circles. In Astronomy, secondary circles are great circles of the sphere perpendicular to another great circle, which is regarded as the primary, and they consequently pass through the poles of the sphere. The secondaries of the ecliptic are the circles on which the latitudes of celestial objects are measured.

Secondary Quills. (*Secondariæ*, Linn.) The large feathers of the wing which arise from the bones of the antibrachium or fore-arm, and principally from the ulna, are so called.

Secondary or **Mesozoic Rocks.** The great series of rocks occupying geologically the position intermediate between the Palæozoic and the Tertiary series. For an account of the rocks forming the group, see DESCRIPTIVE GEOLOGY.

The secondary series of rocks are admirably developed in England. Except the limestone near the base of the whole series [MUSCHELKALK], there is hardly a European secondary rock of the smallest importance that is not well and thoroughly represented in the British series, while many are with us exhibited in such interesting groups as to enable us to deduce a history of the period much more complete than can be learnt elsewhere. The oolites are especially rich in English geology, and pass upwards into the lower greensand [NEOCOMIAN] by the intervention of the Wealden, a deposit nearly wanting elsewhere, and not replaced by any important rock.

In consequence of this admirable developement, the English geologists have elevated the subdivisions of the series into an importance not warranted by what is known in European countries. In Asia and America, secondary rocks are still less important than on the mainland of Europe.

The secondary rocks include in England the best limestones for building purposes, but no marble properly so called. In the Alps, the rocks of this kind are much more metamorphosed, and exist on a far grander scale. The key to the complications of the Alpine system has, however, often been found by a close study of English rocks and their fossil contents.

The secondary rocks are extremely rich in fossils, and are remarkable for the number and variety of bones of reptiles found in them. The period has for this reason been called the Age of Reptiles. It is not less remarkable for the abundance and variety of cephalopodous molluscs, of which a vast number of groups exist, and which also seem to have been characteristic of the period. There can be little doubt that the unusual richness of the secondary period in organic remains is due to the fact that land was at no great distance from the localities where the rocks are best shown.

Secretary. An officer employed in writing letters, despatches, &c., under the orders of his superior. The title of secretary was first used to denote a public minister in France,

where the three clerks of the privy council were also termed secretaries, as early as the fourteenth century.

There are two secretaries of the navy, who are really the secretaries to the Board of Admiralty: of these one holds a permanent appointment, and the other is the parliamentary mouthpiece of the board, changing with the ministry. Each flag-officer also has a secretary to conduct his correspondence, the latter appointment being generally given to a paymaster or an assistant paymaster.

Secretary Bird. [GYPOGERANUS.]

Secretary, Lord. A high officer in the kingdom of Scotland, resembling the great prothonotary in foreign courts. This office was kept up after the Union, but has been disused since 1746.

Secretary of State. One of the highest officers of the British crown. This office, however, is comparatively modern in point of importance; the secretary of state having been originally what his name implies, a mere servant of the privy council. There was only one until the reign of Henry VIII., who added another; but their functions were limited to preparing business for the council board, which they attended afterwards with their proposals. Under Elizabeth, they became members of the council. Queen Anne raised the number to three, by the appointment of a secretary for Scotch affairs, an office which did not long continue; and one for the American department was appointed in the reign of George III., but abolished in 1782. At present there are five secretaries of state: for the Home Department; the Colonies; for Foreign Affairs; War; and India. In each of these departments there are two under-secretaries, one of whom remains in office on a change of ministry. The Alien Office is annexed to the Home Department. The State Paper Office belonged alike to the three first departments, until the recent changes of this department placed it under the control of the Master of the Rolls. [RECORD.] The secretary for home affairs has the custody of the privy signet; and the Privy Signet Office, in which grants, letters, &c., sealed with the privy signet, are made out, is in his department. The principal secretaries are always ex officio cabinet ministers. Their position in the English government is, in fact, identical with that of the ministers of home and foreign affairs, &c., in France and other Continental countries. Each of them may be said, in a general way, to have the management of all the executive business of his department, subject only to the duty of consulting his colleagues of the cabinet on matters which he deems of sufficient importance. But in any matter requiring advances from the funds at the disposal of the crown, whether British or Colonial, the secretary of state cannot act without the concurrence of the lords of the Treasury, except in the case of India, which has its separate financial administration. No rule prevails as to the selection of secretaries of state from the House of Lords or that of Commons. The secretary for Ireland is also keeper of the privy seal of that part of the kingdom, and chief secretary of the lord lieutenant. His office is divided into two departments, military and civil, in each of which an under-secretary is placed; he is sometimes a member of the cabinet.

Secretion (Lat. secretio). The process by which substances are separated from the blood in animals, or from the sap of vegetables.

In some cases a secretion appears to be a mere separation of water, and of other substances held in solution by it, from the blood; but in others the process is much more elaborate and intricate. A highly complicated glandular structure is requisite; and the proximate or ultimate elements of the blood are arranged into new combinations, so as to constitute a new and distinct product, of which no traces are to be found in the healthy blood. The animal secretions are arranged by Bostock under the heads aqueous, albuminous, mucous, gelatinous, fibrinous, oleaginous, resinous, and saline. Magendie's classification of the secretions comprises, 1. Exhalations, as from the skin, the surfaces of the closed cavities of the body, and the lungs; 2. Follicular secretions, which are either cutaneous or mucous, and, 3. Glandular secretions, such as milk, bile, urine, saliva, &c. [BOTANY; PHYSIOLOGY; &c.]

SECRETION. In Botany, this term is applied to any organic but unorganised substance produced in the interior of plants.

Sect (Lat. secta). A term used in ordinary language to signify any body which separates from the established religion of a country; originally the term was applied to the *followers* of some distinguished person, and seems to be derived from Lat. sequor, *I follow*. The chief sects, both of philosophers and religions, will be found noticed under their respective heads.

Sectile (Lat. sectilis, *that may be cleft*). In Botany, a term applied to bodies which are cut into small pieces, as the pollen masses of some orchids.

Section (Lat. sectio, from seco, *I cut*). The projection or geometrical representation of a building or other object, supposed to be cut through, so as to exhibit its interior configuration.

SECTION. In applied Geometry, the *surface* formed when a solid is cut by a plane. In the theory of surfaces, the term section is applied to the curve in which one surface is cut by another. Thus, the *plane section* of a plane is a right line, while that of a sphere is a circle. The plane sections of a cone are termed CONIC SECTIONS. In general the section of a surface of the m^{th}, by another of the n^{th} order is a curve of double curvature of the mn^{th} order, i.e. a curve which is cut by a plane in mn points. [CURVE.]

The name *angular sections* was given by Vieta to that branch of analysis in which the trigonometrical functions of multiples

and submultiples of an angle are investigated. Euler, Lagrange, Poinsot, and many others, have written on this subject; their results are now incorporated in every good treatise on plane trigonometry.

Section of a Ratio and *Section of a Space* are terms employed by Apollonius of Perga, who wrote two books with those titles; the former of these terms was restored by Dr. Halley, and the latter by Willebrord Snell.

Sections. In Shipbuilding, vertical planes at right angles to the keel, taken at any part of a vessel's length to assist the builder. The *body-plan* represents a collection of these sections developed on the largest of them all, the midship section.

Sector (Lat.). In Astronomy, an instrument constructed for the purpose of determining with great accuracy the zenith distances of stars passing within a few degrees of the zenith, where the effect of refraction is small. [ZENITH SECTOR.]

SECTOR. In Geometry, the *sector of a circle* is the figure bounded by two radii and the intercepted arc. Sectors of different circles are said to be *similar* when the sides or radii include equal angles. The area of a sector is equal to that of a triangle whose base is equal to the length of the contained arc, and whose altitude is equal to the radius of the circle.

SECTOR. A mathematical instrument, of considerable use in making diagrams, laying down plans, &c. Its principal advantage consists in the facility with which it gives a graphical determination of proportional quantities; and hence it is called by the French *the compass of proportion.*

The sector may be used in trigonometry for obtaining a rough solution of all the cases of right-angled plane triangles; and it is also conveniently applied to the construction of various geometrical problems. For a description of the instrument and of its different uses, see Robertson's *Treatise of such Mathematical Instruments as are usually put into a Portable Case.*

Sectoral Barometer. An instrument, invented by Magellan, in which the height of the mercurial column is found by the angle at which it is necessary to incline the tube in order to bring the mercury to a certain mark on the instrument.

Secular (Lat. sæcularis, from sæculum). The Latin word sæculum, besides the meaning of a century or generation of mankind, had that of a number, or race—*sæcla ferarum* (Lucret.), and was also used to signify the fashion of the time, or the *age*, as we should now say—corrumpere et corrumpi, sæculum vocatur (Tacitus). Hence, Christian writers came to employ it in the sense of *the world*, in opposition to the *church*. And thus, again, in still later times, the *secular clergy*, i.e. the parochial priesthood, engaged about the affairs of the world, were opposed to the *regular*, i.e. clergy belonging to religious orders who lived under *rule*. Hence, in Politics, the appropriation of religious property to non-religious uses is termed *secularisation*. This took place, in England, by the gradual absorption of tithes belonging to the church by lay incumbents; and on a large scale by the measures of Henry VIII. at the Reformation. In most Continental states, secularisation of church property has taken place on a larger scale than among ourselves. [MONACHISM.]

Secular Equation, Secular Inequality. In Astronomy, any deviation from the mean motion or mean orbit of a celestial body is called an *inequality*, and the numerical expression of the magnitude and period of the inequality is called an *equation*. The equations representing the motions of the bodies of the solar system are of two kinds, *periodic* and *secular*: the first being those which pass through all their changes and return to the same state in a comparatively short period of time; and the second such as change their value so slowly that the variation becomes sensible only after the lapse of centuries, and require for the accomplishment of the series of their changes a length of time which in some cases astronomers have not yet ventured to calculate. Thus the lunar *evection*, which depends on the position of the transverse axis of the moon's orbit in respect of the line of the syzygies, is a *periodic* inequality, passing through all its different values in about 31 days 19¼ hours; but the acceleration of the moon's mean motion, depending on a slow variation of the eccentricity of the earth's orbit, is a *secular* inequality, amounting only to about 10 seconds in a century. The secular inequalities are, in fact, periodic as well as the others; but they proceed so slowly that the observations of many hundreds, or even thousands of years, would be insufficient to make known their periodicity. The discovery of their true nature is one of the results of the theory of gravitation.

Secular Games. In Roman Antiquities, games celebrated once in each sæculum. They lasted three days and three nights, during which time sacrifices were offered up, and theatrical shows exhibited, and combats in the circus, &c., took place. Valerius Publicola, the first alleged consul created after the expulsion of the kings, is said to have been the first who celebrated them at Rome. Some authors maintain that the *sæculum*, or age, consisted of 100, and others of 110 years; but several Roman emperors did not allow so long an interval as either period to elapse. Thus, Augustus celebrated secular games A.U. 736, Caligula 64 years later, and Domitian 26 years afterwards. According to Zosimus, the emperor Septimius Severus was the last who celebrated them; but other writers have stated that under the emperor Philip, A.U. 1000, these games were held with more magnificence than had ever been before witnessed. (Gibbon's *Roman Empire*, ch. vii.) They were celebrated, in all, eight times.

The original sæculum of the Etruscan augurs

is said by some to have been measured by the longest life of those who were born at its commencement; and they had a tradition, that the duration allotted to nations was measured by a certain number of these sæcula. (Plutarch, *Sulla*; Censorinus, *De Die Natali*.)

Secular Poems. Poems recited at the celebration of the SECULAR GAMES. Of this species of poem, the secular Sapphic Ode of Horace is a noble specimen.

Secular Refrigeration. The periodical cooling and consequent consolidation of the crust of the globe: a term formerly used by geologists in reference to the supposed central heat, and even fluidity of the globe, and to the phenomena of its gradual refrigeration.

Secular Year. [JUBILEE.]

Secularisation. [SECULAR.]

Secund (Lat. secundus, *next in the same rank*). In Botany, this term is applied when all the flowers or leaves or other organs of a plant are turned towards the same side.

Secundine. In Botany, the outermost but one of the enclosing sacs of the ovulum, immediately reposing upon the primine. Mirbel considers it the second integument formed by the ovule; Schleider says it is the first, and that the primine or first integument of Mirbel is formed afterwards.

Secundines. In Zoology, the fœtal membranes collectively are sometimes so termed.

Secures. [FASCES.]

Securidaca (Lat. securis, *a hatchet*). A genus of *Polygalaceæ*, chiefly inhabiting tropical America. The Buaze fibre plant, spoken of by Dr. Livingstone, is *S. pallida*. It is a bush of from four to eighteen feet high, with pale green leaves, and small dingy purple flowers, and grows in rocky places at the foot of hills near the Zambesi and Shire Rivers, as well as in Mozambique. The twigs are cut by the natives in January and February for the sake of the fibre, of which they make cord, fishing-nets, &c. The fibre resembles flax. Many of the South American species ramble to a great height over other trees, and are beautiful objects when in flower.

Securifers (Lat. securifer, from securis, *a hatchet*, and fero, *I bear*). The name of a tribe of *Terebrantia*, or boring Hymenopterous insects, comprising those in which the females have a saw-shaped or hatchet-shaped terebra or appendage to the posterior part of the abdomen for the purpose of preparing a place to receive the eggs, and of depositing them therein.

Securipalps (Lat. securis, *a hatchet*; palpo, *I touch softly*). The name of a family of Coleopterous insects, comprehending those in which the maxillary palps terminate in a joint which is elongated and hatchet-shaped.

Secutores (Lat. *followers*). A name supposed by some to have been given to GLADIATORS, who followed the retiarius, when he had failed to secure his antagonist with the net. By others, they are supposed to be the suppositii, i.e. those who followed or were put in the place of gladiators already slaughtered.

Sedatives (Lat. sedo, *I calm*). Medicines which assuage pain; generally by inducing sleep and diminishing irritability.

Sedentaries. The name of a section of spiders (*Araneidæ*), comprehending those which remain motionless in the hiding-place of their web until called forth by an entangled prey.

Sederunt (Lat.). A term used in Scotland in the minutes of courts and other bodies, meaning that '*they* (naming the members) *sate* on such a day': hence applied to mean a *sitting* of such court or body.

Sedge (A.-Sax. secg). The common name for *Carex*. What is called Sweet Sedge is the *Acorus Calamus*.

Sedge Bird. The name of the *Sylvia phragmitis*, Bech. This species of warbler visits this country about the middle of April, and emigrates in September. It frequents the sedgy banks of rivers, and constructs a nest composed of a little moss intermixed with dry stalks, lined with dry grass, and occasionally a few hairs. It lays five or six eggs of a light brown colour, mottled with darker shades of the same. It is sometimes called *reed bunting*.

Sediment Collectors or **Scale Pans.** Vessels suspended in a boiler, for collecting the portions of the sediment which are brought to the surface by the bubbles of steam. These portions would otherwise settle to the bottom of the boiler or on the flues, and form scale. Sediment collectors are not now much used, but the sediment which is ballooned to the surface is blown out at once.

Sedition (Lat. seditio). In Law, a general and not strictly technical word, comprising, in common language, offences against the state which do not amount to high treason. The distinction betweeen the two offences was not very accurately adhered to or defined until later times. Sedition is of the like tendency with treason, but without the *overt acts* which are essential to the latter. Thus, there are seditious assemblies, seditious libels, &c., as well as direct or indirect threats and acts amounting to sedition; all punishable as misdemeanours.

Seduction (Lat. seductio, a *leading aside*). In English Jurisprudence, seduction is regarded as ground for civil action only, brought by the father of the injured person on the technical ground that he has lost, by reason of the wrong thus done, the benefit of the service of the injured party. Being grounded on this fiction, the action is maintainable by a master on behalf of his female servant.

Sedum (Lat. *a house-leek*). This genus of Crassulaceous plants is remarkable for its succulent leaves, and terminal cymes of yellow, white, or purple flowers. The structure of *Sedums* is such as to enable them to vegetate for a long time without absorbing moisture from the earth. There are several British species, the most common of which, *S. acre*, the Stonecrop, is a low plant with tangled stems, short fleshy leaves (which are produced into a kind of spur at the base), and golden yellow flowers.

See (Lat. sedes, *a seat*). The name usually given to the diocese of a bishop. It was originally applied exclusively to the papal chair at Rome; but it has long been used in its present wide signification.

Seed (A.-Sax. sæd, Ger. saat). In Botany, the reproductive part of a plant resulting from impregnation, and containing the embryo or rudiment of a future plant. In other words, it is the ovule in its most perfect and finally organised state. It is a form of reproductive matter peculiar to flowering plants, its equivalent in flowerless plants being the spore. It is commonly said that as the seed is the part intended by nature to multiply the races of plants, special contrivances are provided for insuring its dispersion and migration from place to place; such, for instance, as being discharged with force by the sudden explosion of the case or seed-vessel in which it is generated, having membranous wings that render it buoyant, and so on. But this idea, although to a certain extent true, is frequently misapplied to seed-vessels, as in the instance of the Dandelion, the Ash-tree, the Sycamore, &c.: in these latter cases the part to which the name of seed is given is a true pericarp or seed-vessel. On the other hand, many kinds of seed-vessels, such, for instance, as those of corn, of labiate and boraginaceous plants, &c., are miscalled seeds, or naked seeds.

Seed Lac. [Lac.]

Seed Pearl. [Pearl.]

Seg. An East Anglian form of the word *sedge*, applied to rushes, reeds, and sedges. The name Segg is applied in some parts of the country to the common Flag, *Iris Pseudacorus.*

Seggars. [Porcelain.]

Segment (Lat. segmentum, *a part cut off*). In Geometry, any part cut off from a figure. Thus, the *segment of a line* is the part which lies between two of its points. The *segment of a circle* is the part cut off by a chord. *The segment of a sphere* is the part cut off by any plane, &c. The *angle of a segment*, in the case of a circle, is the inclination of the arc to the chord; in the case of a sphere, it is the inclination of the spherical surface to the plane. Segments whose angles are equal are said to be *similar*. The area of a circular segment is found by deducting from the area of the corresponding sector that of the triangle whose base is the chord. With respect to the superficial area and the volume of a spherical segment, see Sphere.

Segment Shell. In Artillery, an elongated shell, invented by Sir W. Armstrong. It consists of a body of iron coated with lead; inside the body a number of segments of iron are built up in successive rings, leaving a hollow cylinder in the centre for the bursting charge. On the explosion of this bursting charge the segments are scattered; but, on the principle of the arch, they strengthen the shell and prevent its being broken by any external blow: and so the projectile can be used as solid shot. It may also be used as case, by regulating the fuze so as to burst the shell on leaving the muzzle.

Segno (Ital. *a mark*, Lat. signum). In Music. [Al Segno.]

Segregation (Lat. segregatio, *a separating*). That process in nature by which, when a mixed mineral mass has been deposited or accumulated and left to the influence of the chemical forces always operating, certain minerals tend to separate themselves from the mass and collect into natural cracks or blisters either previously existing or formed during the operation. It sometimes happens that instead of occupying cracks or blebs the separating part forms belts or bands. Calcareous rock separates in this way from clay, and many volcanic minerals from lava.

Segue (Ital. *it follows*). In Music, a word which, prefixed to a part, denotes that it is immediately to follow the last note of the preceding movement. When minims, crotchets, &c., are subdivided by a stroke drawn through their tails, so as to make them into abbreviated groups, the term indicates that the following notes are divided similarly to those first marked.

Seguiera (after J. F. Sequier). A genus of *Petiveriaceæ*, comprising a few South American shrubs, smelling more or less strongly of garlic or assafœtida; the whole plant, root, wood, and herbaceous parts, having this powerful odour. On this account, baths impregnated with *S. alliacea* are in repute in Brazil in cases of rheumatism, dropsy, and hæmorrhoidal affections. The wood abounds in potash, and the ashes are employed in clarifying sugar, and in soapmaking in Brazil.

Seicentisti (Ital.). In Literary History, the Italian writers of the seventeenth century. As these stood lower than the writers of the latter part of the preceding century, who had themselves declined from the earlier standard, the name became associated with the idea of false taste and expression. (Hallam, *Literary History*, part iii. ch. v. § 1.)

Seidlitz Water. The mineral water of Seidlitz, a village of Bohemia: sulphate of magnesia, sulphate of soda, and carbonic acid, are its active ingredients. It is often taken as an agreeable and effective aperient. The article sold under the name of *Seidlitz powders* is intended to produce the same effect, though very different in composition. These powders are generally sold in different coloured papers: one blue, containing 2 drachms of the potassa-tartrate of soda mixed with 2 scruples of bicarbonate of soda; the other red, containing 35 grains of finely powdered tartaric acid. The former powder is dissolved in half a pint of water, and the latter in a separate wine-glassfull; the solutions are then mixed, and taken in the act of effervescence.

Seigniory (Fr. seigneurie). In Feudal Law, a manor or other lordship.

Seignorage. In Finance, the charge levied by government to cover the expense of coinage, or to serve as a fund from which public income

may be derived. The seignorage, if levied at all, must not be too high, else it affords an almost irresistible temptation to private coining, and as it must be high in order to form any important branch of revenue, it is generally no more than is thought sufficient to cover the cost of minting. The effect of a seignorage is to make coin more valuable than bullion.

In this country no fixed seignorage is levied on gold, which is the standard of value. Any person may have standard gold coined in quantities of not less than 10,000*l*., at the public cost. The short delay, indeed, during which the manufacture takes place would amount by the interest on the specie to a slight seignorage; but as the coinage is carried on through the agency of the Bank of England, and no private person can employ the agency of the mint for obtaining sovereigns, the loss is not really incurred, and such a seignorage as might affect the private individual does not take effect on the Bank issues of coin. In France, however, coin is worth more than bullion, by reason of the seignorage, and when monetary transactions take place between this country and France, coin must be treated as bullion. The absence of uniformity in the monetary systems of Europe is, irrespective of the weights of the several denominations, a serious hindrance and loss in international trade, and an inconvenience which calls urgently for a reform based on a mutual understanding. No greater advantage could be given to nations, and none could more fully serve the purpose of uniting them by common interests, than an intelligible system of mutual and easily adjusted currencies.

A considerable seignorage is levied on the silver and copper currencies in this country. But this does not in the least degree affect values. Neither are legal tenders in anything but small amounts, and both are an exclusively local currency, since the exportation of silver coin at its nominal value would entail a loss of upwards of 8, the exportation of copper coin fully, on an average, a loss of 100 per cent. [CURRENCY; MONEY.]

Seirens (Gr. Σειρῆνες). In Greek Mythology, beings who so charmed mariners by the sweetness of their song, that they steered their ships to the spot from which the sweet sounds came, and were lost among the breakers. When ODYSSEUS was returning home from Troy, the wise Kirkê (Circe) told him that he could avoid the danger only by stuffing the ears of all his sailors as well as his own with wax, as long as they remained within hearing of their voices. Odysseus followed this advice strictly in the case of his sailors; but, wishing to hear the song, he left his own ears unstopped, and had himself lashed to the mast. His entreaties to be loosed were thus disregarded by the sailors, who could not hear the songs which charmed Odysseus.

This legend has been applied by many to show that the poet designed to convey a moral lesson on the enticements of evil pleasures, and to exhibit in Odysseus an example of firm resistance to temptation; but the incidents just related completely overthrow such a supposition.

According to the *Odyssey*, the island of the Seirens lay between Æaea and the rock of SCYLLA; but that poem does not mention their numbers. Later myths not only define their number, but specify their names, while they also vary in the accounts given of their abodes.

Seisachtheia (Gr. σεισάχθεια, literally *a shaking-off of burdens*). The disburdening ordinance which formed the first step in the legislature of Solon. The Solonian poems prove the extreme misery and degradation of the poorer Attic freemen under the existing laws of debt. These evils had risen to such a height that the laws could no longer be enforced, and Solon, it is said, resolved on a measure which should completely extirpate them. His seisachtheia, in Mr. Grote's words, 'cancelled at once all those contracts, in which the debtor had borrowed on the security either of his person or of his land; it forbad all future losses or contracts in which the person of the debtor was pledged as security; it deprived the creditor in future of all power to imprison, or enslave, or extort work from his debtor, and confined him to an effective judgment at law authorising the seizure of the property of the latter.' (*History of Greece*, part ii. ch. xi.)

On the purport and extent of this ordinance many opinions have been entertained. While some ancient writers regarded it as having cancelled all money contracts, others held that it simply lowered the rate of interest and depreciated the currency, leaving the letter of the contracts untouched. The latter notion seems to be refuted by the Solonian fragments, while the debasement of the coinage disproves the former supposition, for with the rescinding of all contracts the need of any debasement is at once removed. It cannot, however, be maintained that the relief so given involved injustice to none, for the creditors were unquestionably deprived of money or gains to which they were legally entitled; but the measure, as Mr. Grote urges, is to be vindicated 'by showing that in no other way could the bonds of government have been held together, or the misery of the multitude alleviated. We are to consider, first, the great personal cruelty of the pre-existing contracts which condemned the body of the free debtor and his family to slavery; next, the profound detestation created by such a system in the large mass of the poor against both the judges and the creditors by whom it had been enforced. . . . Moreover, the law which vests a creditor with power over the person of his debtor, so as to convert him into a slave, is likely to give rise to a class of loans which inspire nothing but abhorrence—money lent with the foreknowledge that the borrower will be unable to repay it, but also in the conviction that the value of his person as a slave will make good the loss, thus reducing him to a condition of extreme misery, for the purpose

sometimes of aggrandising, sometimes of enriching the lender. Now, the foundation on which the respect for contracts rests, under a good law of debtor and creditor, is the very reverse of this. It rests on the firm conviction that such contracts are advantageous to both parties as a class, and that to break up the confidence essential to their existence would produce extensive mischief throughout all society.' And, finally, it must be remembered that this measure settled the question to which it referred. In striking contrast to the agitation of Roman society arising from the same evils, the law of debtor and creditor never again disturbed the peace of Athenian citizens.

Seisin. In the Law of England, seisin signifies the feudal possession of land.

Seisin, Livery of. The formal delivery of the possession of land, formerly essential to its transfer, but now disused.

Seismology. [EARTHQUAKES.]

Seismometer (Gr. σεισμός, *an earthquake*, and μέτρον). An instrument for measuring the shock of earthquakes and other concussions.

Sejant. In Heraldry, a term employed to describe beasts when represented in a sitting posture. *Sejant-rampant*, sitting with the two fore feet lifted up, &c.

Selacians (Gr. σέλαχος). The name given by Cuvier to the tribe of Chondropterygians which includes the rays and sharks.

Selaginaceæ (Selago, one of the genera). A small order of Perigynous Exogens, agreeing with *Verbenaceæ* in their irregular flowers, two or four stamens, and free two-celled ovary not lobed, with one ovule in each cell; but differing from that order, as well as from the closely allied *Myoporaceæ*, in the anthers being always one-celled only. They are all herbs or small shrubs, and chiefly from Southern Africa. *Selago* itself, the typical genus, contains upwards of seventy species, herbs or undershrubs, with small entire somewhat alternate leaves, and sessile spiked two-lipped flowers.

Selaginella. This genus of *Lycopodiaceæ*, the largest in the order, is distinguished from *Lycopodium* by its flat two-ranked stem, and its two forms of two to three valved fruit, one of which contains large pallid spores, the other free spore-like orange or scarlet antheridia, which at length produce spiral spermatozoids. The species vary greatly in size, some being minute, resembling the larger *Jungermanniaceæ*, while others attain a considerable size. The leaves, which sometimes assume a bluish tint, are generally of different sizes. The numerous species are inhabitants of warm regions, and frequently, being extremely elegant, are favourite objects of cultivation. *S. convoluta* has the fronds curiously curled in and contracted when dry, so as to form a ball like the Rose of Jericho, which expands when moistened. *S. mutabilis* has the remarkable property of changing its colour every day, being in the morning of a bright-green, but as the day advances becoming gradually pale, and at night resuming its deeper tint.

Selbite. A massive mineral of an ash-grey to a black colour, and very soft, found at Altwolfach in Baden, and in Mexico. It is composed of carbonate of silver with about 15 per cent. of carbonate of antimony with oxide of copper; but, probably, it is only a mechanical mixture. Named after Selb, by whom it was analysed.

Selene (Gr. *the moon*). In the Hesiodic *Theogony* (371), a daughter of HYPERION and Theia, and a sister of Helios and Eos. Selene is the lover of ENDYMION, the sinking sun; and she was also known as Asterodia, the wanderer among the stars. These words displayed their meaning to the Greek in his own language, and hence the original idea was more clearly retained than in legends which grew up about names that had lost their significance, as in the myth of Argynnis (the beloved of Agamemnon), which in Sanscrit is *Arjuni*, a mere epithet denoting the brilliancy of the morning.

Selenite (Gr. Σεληνίτης). The name generally applied to transparent crystallised Gypsum. It is a hydrated sulphate of lime, and generally occurs in flattish, white, transparent crystals, which are easily susceptible of cleavage into thin laminæ that are flexible but not elastic. Selenite is found in many places; generally in clay, as in the London clay of London and Surrey, and of Walton-on-the-Naze in Essex; in the Eocene clays of the Isle of Wight, in Alum Bay, &c.; in the Oxford clay of Shotover Hill, Oxfordshire; in the Lias of Gloucestershire, the Gault of Folkestone, &c.

Selenium (Gr. Σελήνη, *the moon*). A substance discovered in 1818 by Berzelius. In its general chemical habitudes it bears a resemblance to sulphur. It has hitherto been obtained in very small quantity, and generally occurs in some of the varieties of iron pyrites. It is a brittle opaque substance, tasteless, and inodorous; having something of the appearance of lead, but of a deep red colour when reduced to powder. Its specific gravity is about 4·3. At 212° it becomes soft and tenacious, and at 220° is perfectly liquid; at 650° it boils and sublimes. It is insoluble in water, and unaltered by air; and when heated by the blowpipe, so as to become oxidised, it exhales a strong odour of horse-radish. Its equivalent is about 40. It forms an oxide and two acids; the *selenious acid* being a compound of 1 equivalent of selenium and 2 of oxygen, and the *selenic acid* of 1 and 3. It also combines with hydrogen, forming the *hydroselenic acid*, a gaseous compound of 40 selenium + 1 hydrogen. Its odour at first resembles sulphuretted hydrogen, but afterwards it powerfully irritates the nose, excites catarrhal symptoms, and destroys the sense of smell. Dr. Prout has suggested the possibility of the evolution of this compound by volcanoes, and its diffusion through the atmosphere as productive of certain forms of the epidemic disorder called influenza.

Selenography (Gr. Σελήνη, and γράφω, *I describe*). The description of the surface of

the moon, as geography is a description of the surface of the earth.

Seleucidæ, Era of the. In Chronology, the era of the Seleucidæ, otherwise called the Macedonian era, dates from the epoch of the first conquests of Seleucus Nicator in Syria, about 311 years B.C. It was followed generally by the Greek colonies bordering on the Levant; and by the Jews till the fifteenth century, by whom it was called the *era of contracts*. There is considerable difference of opinion among authors respecting the month and day on which the year of this era commenced, so that it is frequently not possible to fix the correspondence of dates; but, according to the computation most generally followed, the year 312 of the era of the Seleucidæ began on September 1 in the Julian year preceding the first year of our era. Hence, to reduce a Macedonian date to the common era, subtract 311 years and 4 months.

Self-conjugate Triangle. [CONJUGATE TRIANGLE.]

Sella Turcica. A cavity in the *sphenoid* bone; it is surrounded by the four clenoid processes, and contains the pituitary gland.

Selli. The priests of ZEUS, who delivered his oracles at the sacred grove of Dodona in Thessaly. (Gladstone's *Homer and the Homeric Age*, i. 108.)

Selters or **Seltzer Water.** A mineral water from Seltzer, about ten miles from Frankfort-on-the-Maine. It is an agreeable beverage, from the quantity of free carbonic acid which it contains, and which covers its slightly saline taste. Common salt, with the carbonates of magnesia, lime, and soda, are the saline ingredients. [MINERAL WATERS.]

Selvage or **Selvagee.** A piece of very flexible rope, composed of yarns not twisted together, but laid parallel, and confined externally by marline.

Semaphore (Gr. σῆμα, *a sign*, and φέρω, *I bear*). A term mostly used synonymously with *telegraph*, but which, as its derivation imports, may be applied to any means employed to communicate intelligence by signals. [TELEGRAPH.]

Semé (Fr. *sown*). In Heraldry, a term employed to describe a field or charge powdered or strewed over with figures, such as stars, billets, crosses, &c.

Semecarpus. A genus of Indian trees belonging to the *Anacardiaceæ*, one species, *S. Anacardium*, being the Marking-nut tree of India. The thick fleshy receptacle bearing this fruit is of a yellow colour when ripe, and is roasted and eaten by the natives. The unripe fruit is employed for making a kind of ink, and when pounded serves to form a kind of birdlime. The hard shell is permeated by an acrid corrosive juice, which is employed externally in rheumatic affections, as well as for destroying warts, but its acridity sometimes causes much inflammatory swelling. This juice, when mixed with quicklime, is employed to mark cotton or linen with an indelible mark. When dry, it forms a black varnish, much used in India; and amongst other purposes it is employed, mixed with pitch and tar, in the caulking of ships. The seeds, called Malacca-beans or Marsh-nuts, are eaten, and are said to stimulate the mental powers. From them an oil is procured, which is used in painting.

Semeiotic (Gr. σημειωτικός, from σημεῖον, *a sign*). That which relates to the signs or symptoms of diseases.

Semelê (Gr.). In Greek Mythology, a daughter of Cadmus and Harmonia, and sister of Agavê. [PENTHEUS.] In the Theban legend, she was beloved by Zeus; and Hera, moved by jealousy, appeared before her in the form of her nurse Beroe, and incited her to demand from Zeus a manifestation of his splendour when next he came to visit her. Zeus, being already under promise to give whatever she might ask, granted her prayer; and Semelê was accordingly scorched by the lightnings, while Dionysus, her child, was born amidst the flames. The Laconian version relates that, after giving birth to Dionysus, she was (like Danaê, the mother of PERSEUS) cast forth in a boat, and that her body was thrown up lifeless on the coast near Brasiæ, where Dionysus was brought up.

Semen Contra (Lat.). The Pharmaceutical name for a drug composed of the dried leaves and flower-heads of *Artemisia Sieberi*, and some allied species. It is a celebrated vermifuge. *Semen cinæ*, or *Semencine*, is a drug of similar character, obtained from several species of the same genus.

Semi-Arians. A branch of the Arians, who denied the ὁμοούσιον, or *consubstantiality* of the Son with the Father; but admitted the ὁμοιούσιον, or *similarity of substance*. [ARIANS; HOMOOUSIANS.]

Semi-cubical Parabola. [PARABOLA, SEMI-CUBICAL.]

Semi-Pelagians. The Semi-Pelagians differ from the PELAGIANS in maintaining the necessity of the divine grace towards the practice of virtue; but at the same time conceive that this grace may be obtained by an effort of the human will. (Milman's *Latin Christianity*, book ii. chap. ii.)

Semi-regular Polyhedrons. [POLYHEDRON.]

Semibreve. In Music, a note whose length is half that of a breve. It is the longest note generally used in modern music, and is the integer whose fractions are usually adopted to express the length of other notes.

Semicircle. In Geometry, the half of a circle; or the figure bounded by the diameter and half the circumference.

Semicolon. [PUNCTUATION.]

Semidiameter. In Geometry, half of the diameter; or the part of the diameter of any figure comprehended between the centre and the extremity of the diameter.

Semimetal. A term applied by the old chemists to the brittle metals.

Seminary (Fr. séminaire). In the language of the Roman Catholic Church, an esta-

blishment for the maintenance of missionaries intended to be employed in the conversion of infidels and heretics. The chief of all seminaries is that at Rome, entitled also the Apostolical College, but best known under the title of the Seminary or College 'for the Propagation of the Faith.' It was founded by Pope Urban VIII., through the exertions, chiefly, of a Spanish ecclesiastic, Juan-Baptista Virès, of Valencia, in the first half of the seventeenth century. The 'Seminarists' maintained in this establishment are afterwards employed under the direction of the Congregation of Cardinals for the propagation of the faith; as are those of various minor colleges established in Rome for the benefit of particular nations and races. The word *seminary* has since passed into ordinary use for a variety of educational establishments for the clerical order. In France the greater or diocesan seminaries are collegiate institutions; the little seminaries are secondary schools; and all are under the special superintendence of the episcopal authorities.

Seminvariant. The coefficient of the highest power of one of the facients in the covariant of a quantic. Thus the quadri-covariant quartic or Hessian of the binary quartic

$$(a_0, a_1, a_2, a_3, a_4 \between x, y)^4$$

being

$$(a_0a_2 - a_1^2,\ 2a_0a_3 - 2a_1a_2,\ a_0a_4 + 2a_1a_3 - 3a_2^2,\ 2a_1a_4 - 2a_2a_3,\ a_2a_4 - a_3^2 \between x, y)^4,$$

$a_0a_2 - a_1^2$ is a *seminvariant* of that quartic, as also is $a_2a_4 - a_3^2$. To understand the appropriateness of the term, it must be remembered that, according to Prof. Cayley's definition, an invariant is any function of the coefficients of a quantic which is reduced to zero by *each* of the operators which, for the original quantic, are equivalent to $y\frac{d}{dx}$ and $x\frac{d}{dy}$. [INVARIANT.] Now, a seminvariant is reduced to zero by *one*, but not by the other, of these operators. (Salmon's *Higher Algebra*, p. 75.) In the above case, these operators are

$$a_0\frac{d}{da_1} + 2a_1\frac{d}{da_2} + 3a_2\frac{d}{da_3} + 4a_3\frac{d}{da_4}$$

and

$$a_4\frac{d}{da_3} + 2a_3\frac{d}{da_2} + 3a_2\frac{d}{da_1} + 4a_1\frac{d}{da_0}$$

respectively. These functions were originally termed *peninvariants* by Brioschi; the more appropriate term *seminvariant* appears to have been proposed by Cayley.

Seminymph. Lyonnet so calls the nymphs of those insects which undergo but slight changes in passing to the perfect or imago stage.

Semiopal. A silicious mineral, nearly resembling the Common Opal, but differing from it in being harder and more opaque, in exhibiting a less perfect conchoidal fracture, and in the muddiness of its colours. It is found at Okehampton in Devonshire, and in Cornwall at Huel Buller and near St. Ives and St. Just.

Semipalmate (Lat. semi, *half*, and palma *a palm*). In Zoology, when the toes are connected together by a web extending along only their proximal half. The term *semi* being frequently used in the composition of zoological terms with the same meaning, it is only requisite to refer to the term to which it is prefixed.

Semiquadrate or **Semiquartile.** In the language of Astrology, an aspect of the planets when distant from each other half a right angle, or 45°. The terms *semiquintile* and *semisextile* have a similar meaning; the first denoting the *half of a fifth* of the complete circle, that is, 36°; and the second the *half of a sixth*, or 30°.

Semiquaver. In Music, a note whose duration is half that of a quaver.

Semiramis and **Ninus.** In Mythology, the founders of the Assyrian Empire of Nineveh. According to Herodotus (i. 184), Semiramis reigned five generations before Nitocris, whom he represents as the wife of Labynetus, the father of the king of the same name who was reigning at Babylon when it was taken by Cyrus. According to Ctesias, she was the wife of Ninus, from whom Nineveh received its name. In the chronology of Berosus, she follows a series of dynasties consisting of Median, Chaldæan, and other kings. But, in truth, the attempt to assign a historical date or character either to Semiramis or to Ninus is as much labour lost as the effort to fix the date of the birth of the nine Muses, or the death of Medusa. 'Ninus and his queen Semiramis,' says Sir G. Cornewall Lewis, 'appear to be purely fabulous beings. The name of Ninus is derived from the city; he is the eponymous king and founder of Nineveh, and stands to it in the same relation as Tros to Troy, Medus to Media, Perseus to Persia, Ægyptus to Egypt, Lydus to Lydia, Mæon to Mæonia, Romulus to Rome. His conquests and those of Semiramis are as unreal as those of Sesostris. It is the characteristic of these fabulous conquerors, that, although they are reported to have overrun and subdued many countries, the history of those countries is silent on the subject. Sesostris is related to have conquered Assyria; and the king of Assyria was doubtless one of those whom he harnessed to his chariot. But the history of Assyria makes no mention of Sesostris. Semiramis is related to have conquered Egypt; but the history of Egypt makes no mention of Semiramis.' (*Astronomy of the Ancients*, 408.) It is scarcely worth while to notice the version of Dinon and other writers, that Semiramis was a courtesan, who, becoming the wife of Ninus, persuaded him to entrust her for five days with supreme power, of which she availed herself to put him to death and to establish her own dominion. It is more pertinent to remark that her mythical history presents features closely resembling the tales of PARIS, ŒDIPUS, PERSEUS, TELEPHUS, CYRUS, ROMULUS, Chandragupta, and other heroes and founders of dynasties. She is said to have

been a daughter of the fish-goddess Derceto of Ascalon, by whom she was exposed in her infancy. She was saved by doves, as Iamos was preserved by serpents, Paris by a she-bear, Romulus and Cyrus by a wolf or a dog. Like these, again, she is brought up by a shepherd, until her beauty attracts Onnes, one of the king's generals, who marries her. Ninus on seeing her is also captivated by her charms, and Onnes thereupon slays himself. In later traditions, her fame altogether eclipsed that of Ninus; she became the founder of Babylon, the builder of tombs more than a mile in height. To her were ascribed all those works of a prehistoric age, which may be classed with the cloacæ and other great works of ancient Rome; and, having performed wonders during her life, she vanishes from earth, like Romulus and HERACLES, and wings her way to heaven in the form of a dove.

In other legends, she comes forth in a character very different from that of an Amazonian queen. In these tales she is the counterpart of Aphroditê, the lover of Adonis (or Thammuz), and is said to have initiated the use of eunuchs, and introduced the marriage of mothers and sons. She is, in short, ASTARTE, the coarse Oriental ideal of the being whom the Greek described as Anadyomenê, the child of the bright sea-foam.

Semitic Languages. The name of that family of languages which is composed of the Aramaic, Hebraic, and Arabic dialects. The first of these branches is known to us chiefly through the Syriac and Chaldee. The Hebraic is represented chiefly by the ancient language of Palestine, the speech of the Jews being most closely allied to that of the Phœnicians and Carthaginians. The oldest documents of the third or Arabic branch are the Himyaritic inscriptions: this branch includes the Ethiopic or Gees, and the Arabic dialects. The grammatical framework of these languages is quite distinct from that of the Aryan languages; but the most salient point of contrast is perhaps furnished by the fact that the roots of the Semitic dialects, 'as far back as we know them, must consist of three consonants,' many words being 'derived from these roots by a simple change of vowels, leaving the consonantal skeleton as much as possible intact.' (Max Müller, *Lectures on Language*, first series, lecture viii.)

The following is given by Professor Max Müller as the genealogical table of the Semitic family of languages:—

Living Languages	Dead Languages	Classes	
Dialects of Arabic.			Semitic Family.
Amharic.	Ethiopic	Arabic or Southern.	
+	Himyaritic Inscriptions		
" the Jews.	Biblical Hebrew	Hebraic or Middle.	
+	Samaritan Pentateuch (third century A.D.)		
+	Carthaginian, Phœnician Inscriptions		
+	Chaldee (Masora, Talmud, Targum, Biblical Chaldee)	Aramaic or Northern.	
Neo-Syriac.	Syriac (Peshito, second century A.D.)		
+	Cuneiform Inscriptions of Babylon and Nineveh		

Semitone (Gr. ἡμιτόνιον). In Music, the half of a tone. Strictly speaking, this is not a proper definition of it, inasmuch as semitones are of different lengths, according to their nature. A diatonic semitone is when the name of the note changes, as, for example, from C to D♭, or from B to C; a chromatic semitone is when the note is merely altered by a sharp or a flat, as from C to C♯, or from D to D♭.

Semivowel. This term is applied to those consonants which, like vowels, can be pronounced independently, or without the aid of any other letter. To this class belong *b, d, c, g, k, p, s, t, v, x,* and *z*.

Semnopithecus (Gr. σεμνός, *venerable*, and πίθηκος, *an ape*). A genus of long-tailed Catarrhine monkeys, distinguished by the complex stomach, long canines, and the more obtuse facial angle from the other Guenons. The species of this genus are all found in India, where *Semnopithecus Entellus* (Hoonuman, or sacred monkey) has been deified. The slaughter of this animal, even by accident, is punished with severity under the Hindu laws.

Semo Sancus. In Mythology, the name of a Roman god, said to have been originally Sabine. The name Sancus, as connected with *Sancire*, points to his relation to law or an oath; and hence he was looked on as presiding over the laws of nations, hospitality, &c. The name Semo is thought by some to be a contraction for semihomo; but this, although possible, cannot be proved.

Semolina (Ital.; Fr. semoule). A granular preparation of wheat, used in cookery.

Sempervivum (Lat. *living always*). A genus of succulent shrubby or herbaceous plants belonging to the *Crassulaceæ*, and allied to *Sedum*, from which they are distinguished by having about twelve petals, and the glands at the base of the ovaries laciniated if present. *S. tectorum*, the Common Houseleek, is a well-known plant, with thick fleshy leaves arranged in the form of a double rose. It is commonly to be met with on the tops of outhouses and cottages, and is considered to possess cooling properties. *S. cæspitosum* has been known to remain alive in an herbarium for eighteen months, and, when subsequently planted, to grow.

Semuncia (Lat.). A small Roman coin, equivalent to half an ounce, being 1-24th of the Roman pound.

Senate (Lat. senatus; i.e. *assembly of elders*). The deliberative assembly of the Roman people. The members of this council were originally chosen from the patricians, and were probably single representatives of each of the houses of that order: a plebeian senator is first mentioned A. U. C. 355. Romulus is said to have fixed the number at 100, which (the legend says) was doubled on the admission of the Sabines, and increased to 300 by Tarquinius Priscus; the more ancient members and those admitted by this last king being distinguished by the titles of *patres majorum* and *patres minorum gentium*, or senators of the greater and of the lesser houses respectively. In the last ages of the republic, the members of the senate amounted to about 400, and were still further raised by the emperors to 1,000. The members of the senate are said to have been originally chosen by the kings, and afterwards the election fell into the hands of the consuls, military tribunes, and finally of the censors; but the fact of having held certain magistracies, as the quæstorship, and all superior posts, gave a right to this privilege. Under the regal government, the senate, it is said, deliberated on such affairs as the king proposed to them. On the establishment of the republic, the whole power of the state was thrown into its hands, the different magistrates exercising their authority merely as its delegates. The first constitutional check imposed on it was the power of intercession, or negativing their proceedings, granted to the tribunes of the commonalty. Still, while Rome was free, the authority of the senate, though subordinate to the assembly of the people, remained very great. It assumed the guardianship of public religion; the management of the revenue; the appointment of governors to the provinces, whose constitution it settled; the direction of diplomatic affairs; and many other functions of importance. Under the emperors, its power became, in general, little more than nominal; yet the assembly still existed till the occupation of Italy by the Goths in the thirteenth century after the foundation of Rome; and in the last ages of its existence, after the seat of empire had been transferred to Byzantium, it seems to have been the centre of what remained of the old national spirit. After that time, its existence as a council ceased, though the name of senator was still retained by some noble families of Rome as an empty but high-sounding title. The senatorial badges were the laticlave, or tunic with a purple band, black buskins reaching up to the middle of the leg, and a silver crescent on the foot.

The affairs of the Italian and provincial towns of the Roman empire, in imitation of the capital, were administered by senates. See as to these provincial senates, or curiæ, Savigny's *Hist. of the Roman Law*, vol. i.

SENATE. In many republican constitutions of modern times, the upper house of the national assembly has been so called. The senate of the United States [CONGRESS] is composed of two members for each state of the Union. The senators are chosen by the state for six years. The American senate, besides its legislative functions, is also a species of executive council, assisting the president; its consent being necessary for the ratification of treaties, appointment of ambassadors, judges of the supreme court, heads of departments in the administration, &c. It is also the high court of impeachment for public functionaries.

Senate was also the title of the upper legislative chamber in France under the first empire; and it has been renewed under the second. The senators are named for life, by the emperor; the number not to exceed 150. The constitutional powers of this body are very extensive, as it can interpret the constitution, decide on the legality of enactments, &c., by *Senatus-consulta* without the concurrence of the Corps Législatif.

Seneca Oil. The name given in some parts of North America to a Petroleum which exudes from the rocks, or floats on the surface of certain springs, after the Seneca Indians, who discovered the oil in Pennsylvania, and used it as a medicine both internally and externally. [NAPHTHA; PETROLEUM.]

Senecio (Lat.). A genus of *Compositæ*, remarkable as being probably the most extensive in point of species in the whole vegetable kingdom. They are spread over all parts of the globe, nearly 900 different kinds being known to botanists. The Groundsel, *S. vulgaris*, and the Ragwort or Ragweed, *S. Jacobæa*, afford a good idea of the appearance of the European species, the most noteworthy of which is perhaps the well-known *S. Cineraria*, better known in gardens as *Cineraria maritima*, extensively used for planting in flower-beds for the sake of contrast with scarlet and other colours, its beautiful foliage being clothed with short white down. The generic name *Cineraria* is, however, restricted to a few Cape plants, which differ from *Senecio* in the achenes of the ray-florets being winged. The beautiful early spring-flowering plants cultivated in greenhouses as *Cineraria* belong to *Senecio*, and have been obtained by horticulturists by intercrossing with each other a number of the Canary Island species, such as *S. populifolius*, *S. tussaliginis*, &c. The deep blue colour of some of the garden forms of these plants is singular in the genus, and not at all common in the family.

Senega Root. The root of the *Polygala Senega*, called Rattlesnake root. It is brought from North America, and has a peculiar pungent flavour, promoting the flow of saliva. In large doses, it nauseates and purges. It is occasionally used in stimulating gargles; and in America, as an antidote—probably a very inefficient one—to the effects of the bite of the rattlesnake. Its active resinous principle has been termed *Senegin*, and also *polygalic acid*.

Senegal Root. The diuretic and very bitter root of *Cocculus Bakis*.

Senegin. The bitter acrid principle of the *Polygala Senega*, or Rattlesnake root.

Seneschal. A French title of office and dignity (said to be derived from the old German word *senne*, house, and *schalk*, servant), answering to that of steward, or high steward, in England. They were originally the lieutenants of the dukes and other great feudatories of the kingdom; sometimes termed baillis or bailiffs. When the kings recovered the rights of suzerainty, and especially the judicial authority, in those provinces which had been previously governed by these great nobles, the bailiffs and seneschals continued as royal judges and superintendents, both military and financial; but their powers, like those of the dukes and counts whom they succeeded, were gradually encroached on by the crown.

Senna. The leaves of various species of *Cassia*, as *C. obovata, elongata, acutifolia*, &c. Large quantities are imported from Alexandria, whither they are brought from Upper Egypt. They are largely mixed with the leaves of *Solenostemma Argel*, which, however, are thick, and not ribbed like the genuine senna leaves. They have a nauseous, mucilaginous, bitter taste, and yield a pale brownish-green infusion. The true senna leaves are distinctly ribbed, thin, generally pointed, and when chewed have a peculiar nauseous flavour, and yield a dark brown infusion. It is a griping, nauseating, and somewhat drastic purge, but a valuable addition to, or vehicle for, other purgatives. Other kinds are imported from India. [CASSIA.]

SENNA. Various preparations of senna are used medicinally, and several different species of the plant are to be found in the markets supplying the drug. The Alexandrian and the Indian senna are chiefly used in this country. The former is collected in Nubia and Upper Egypt from the *Cassia acutifolia* and *obovata*. The latter going by the name of Tinnevelly senna grows in India, but in all probability is only naturalised there. It is the product of *Cassia elongata*. Senna contains a purgative principle called *cathartin*, and also an odorous volatile oil. It is an active purgative, possessing irritant qualities, and is apt to cause tenesmus and pain unless it be combined with aromatics.

Sensation (Lat. sensus, *feeling*). The act by which the mind receives, through parts of the nervous system, impressions of qualities or conditions of nervous bodies. Sensation is *common* or *special*. In its greatest perfection common sensation, or sensibility, constitutes touch. The special kinds are called the SENSES.

Senses (Lat. sensus). The faculties are so called by which we become acquainted with the properties and states of external things. They are five in number—sight, hearing, taste, touch, and smell: for the physiology of which the reader is referred to the articles; such as EYE, EAR, SMELL, &c. [NERVOUS SYSTEM.] Dr. Thomas Brown and Sir C. Bell have propounded the doctrine of a sixth sense, called the *muscular* sense (our whole muscular frame being supposed to be a *distinct* organ of sense)—a doctrine to which Dr. Whewell declared his adherence in his *Philosophy of the Inductive Sciences*, &c. For an able examination of the phenomena of the senses, see Bain's *The Senses and the Intellect*.

Sensibility. [SENSATION; SENSORY.]

Sensitive Plant. This name is generally applied to a small annual, called *Mimosa pudica*, inhabiting the tropics of America. It has a stem about a foot and a half high, covered with stiff hairs; the leaves are bipinnate in a somewhat digitate manner; and the flowers are collected in small pink balls. It derives its name from the irritability of its leaves, which collapse and fold up when touched, or even when irritated by casting on them the focus of a burning glass; or by exposing them to the vapour of hydrocyanic acid. The cause of this irritability has been investigated by Dutrochet (*Mémoires pour servir à l'Hist. Anat. et Phys. des Végétaux*, &c. vol. i. 534), who refers the phenomenon to the action of endosmose, and to the operation of a 'fibrous tissue capable of moving inward under the influence of oxygenation.' The nature of the phenomena may be thus explained: When the leaf of a sensitive plant is at rest, it consists of many leaflets spreading flat, and connected in pairs along the sides of certain common leaf-stalks. When one of these leaflets is irritated, the pair to which it belongs rise upward, and apply their faces to each other; this is rapidly followed by the same action in the succeeding leaflets, and in the course of a few seconds the whole of the leaflets are in a state of collapse; then the leaf itself suddenly bends downwards; and if the plant is in very good health, the shock thus communicated to one leaf will extend to those immediately above and below it. After a time the leaf resumes its original position. Upon the approach of night, that is to say, upon the withdrawal of light, the leaf falls of itself into the same state, without any special irritation.

This kind of irritability is by no means confined to the *Mimosa pudica*; on the contrary, some other species of the same genus, as the *M. dormiens, sensitiva, casta, somnians, palpitans*, &c., possess the same property, as is indicated by their names. And among the Leguminous order, it is also found beyond the genus *Mimosa*, as in the *Hedysarum gyrans*, whose three leaflets are in a continual state of dancing or balancing during the day. In fact, the folding their leaves at night, which is universal in all the compound-leaved species of this order, is the same thing feebly exercised. Nor is such irritability confined to this order; the ternate and pinnate leaved species of *Oxalis*, the *Dionea muscipula*, and numerous other plants, exhibit similar phenomena.

Sensorium (Lat. sentio, *I feel*). A term employed by physiologists for the central seat of sensation or of consciousness. It has been placed by Bontekoe and Lancisi in the *corpus*

callosum; by Willis in the *corpora striata*; by Descartes in the pineal gland; by Vieussens in the *centrum ovale*; by Boerhaave in the boundary line of the grey and white substance; by Mayer in the *medulla oblongata*; and by Camper in the pineal gland and *corpora quadrigemina*. The doctrines of Prochaska, on the contrary, affirm that wherever ganglionic structure exists sensation is also present. The *sensorium* is consequently coextensive with the nervous centres.

Sensory. This term appears to have been first applied by Hartley to those nerves which convey a stimulus to the neural axis or nervous centres with which they are connected, in contradistinction to the nerves which convey a stimulus from the neural axis to the muscles. 'The actions of sneezing, swallowing, coughing, hiccoughing, vomiting, and expelling the fæces and urine' are to be deduced 'from those vibrations which first ascend up the sensory nerves and then are detached down the motory nerves, which communicate with these by some common trunk, plexus, or ganglion.' (*On Man*, vol. i. p. 97.) This class of motions or vibrations, now called *reflex*, Hartley distinguishes from those produced by the transmission of the sensory vibrations to the brain, where they produce *sensation*, and excite *volition*; and the nerves producing the 'first and fourth classes of motory vibrations of Hartley's system' have been asserted to be anatomically distinct from those that produce sensational and volitional vibrations. The distinction has not been recognised, and anatomists apply the term *sensory* to those parts of the neural axis with which the sensory nerves are connected, as e.g. the posterior columns of the myelon, the optic lobes, the thalami and the corpora striata, which are termed *sensory ganglions*.

Sensualism. In Mental Philosophy, that theory which resolves all our mental acts and intellectual powers into various modifications of mere sensation. The best known, and the most elaborate attempt of this kind which has been made in modern times, is that of Condillac, who conceived that he was following out the principles of Locke into their legitimate consequences. For this belief it cannot be denied that there exists at least plausible ground. Locke does indeed draw a distinction between sensation and reflection, as separate sources of *ideas*; but his account of reflection is too vague to justify the attempt to reduce it to mere revived sensation. The theory opposed to sensualism is called *intellectualism*.

Sentence (Lat. sententia, *an opinion*). In English Law, the decree or judgment of the ecclesiastical or admiralty courts is so termed; also, in popular language, the judgment of a criminal court allotting the punishment of a convicted person.

Sentry or **Sentinel** (Fr. sentinelle). The name given to a soldier when posted on guard.

Senza (Ital. *without*). In Music, this term signifies without; as *senza stromenti*, without instruments; *senza violini*, without violins.

Sepals. In Botany, the divisions of that portion of a flower called the *calyx*.

Separate Estate. In Law, this term denotes property given or settled to the separate use and benefit of a woman, in respect of which equity (as administered in the Court of Chancery) treats her as an unmarried person, and she will consequently (notwithstanding her being married, or marrying afterwards) be entitled to it independently of her husband and of his debts, control, and engagements, and he will be bound, where necessary, to confirm and give effect to any disposition of it which she may make. It may be acquired either by prenuptial contract or settlement, or by gift or legacy from a husband or any other person.

Separatists or **Motazalites.** The name of one of the chief sects of the Mohammedans. They were the followers of Wasel Ebn Orta, who dissented from the main body of the Mohammedans about the fortieth year of the Hegira. Their leading tenets consisted in rejecting the eternal attributes of God; in denying the great doctrine of predestination, so zealously cherished by all the orthodox Mussulmans; and in asserting the free agency of man. This sect is said to have been the first inventors of scholastic divinity, and is subdivided into several inferior sects, which mutually brand one another as infidels. (Sale's *Koran*, Preliminary Discourse, vol. i. p. 212.) The great opponents of the Separatists were the Sefatians, who maintained the eternal attributes of God (hence they were called *Sefati*, or Attributists); but who afterwards adopted a belief in the outward resemblance of God to created beings. This sect was afterwards subdivided into various sects, the chief of which were the Asharians, Moshabbehites, Keramians, Jabarians, and Morgians.

SEPARATISTS. This name was given to a sect of Christians which originated in Dublin about the year 1803. Their principle, like that of most sects at their commencement, was to return more nearly to what they conceived to be the primitive form of Christianity. In the year 1833 an Act of Parliament was passed for their relief in the matter of oaths.

Sepawn or **Sepon.** Maize-meal boiled in water, used as food in the North American States.

Sepia (Gr. *the cuttle-fish*). In the Fine Arts, a species of pigment prepared from a black juice secreted by certain glands of the *sepia* or cuttle-fish, which the animal ejects both to darken the water when it is pursued, and as a direct means of annoyance. That this juice was used as ink by the ancients is well known.

> Tunc queritur, crassus calamo quod pendeat humor,
> Nigra quod infusa vanescat *sepia* lympha;
> Dilutas queritur geminet quod fistula guttas.
>
> PERS. *Sat. III.*

Pliny (*Nat. Hist.* l. ii. c. 29) says that it was the property of this fish, when it was enclosed by a net, to shed a black juice which so darkened the water that the fisherman could not see it. All the varieties of the sepia yield this juice; but the *Sepia officinalis*, which is so

common in the Mediterranean, is chiefly sought after for the colour which it affords. [MUREX.] It is insoluble in water, but is extremely diffusible through it, and is very slowly deposited. When prepared with caustic lye, it forms a beautiful brown colour with a fine grain, and has given name to a species of drawing now extensively cultivated for landscapes and other branches of the fine arts. The honour of the invention of the sepia drawing is due to Professor Seidelmann of Dresden, who discovered it at Rome in 1777.

Sepiadæ (Gr. σηπία). Cuttle-fish tribe. The name of the family of Decapodous Dibranchiate Cephalopods, of which the cuttle-fish (*Sepia officinalis*) is the type. They are characterised by the rudiment of a shell, in the form of a friable calcareous plate, embedded in the back part of the mantle, and of which the material called *pounce* is made.

Sepiola (dim. of sepia, *a cuttle-fish*). The name of a genus of Decapodous Dibranchiate Cephalopods, of which the species are of small size, and are characterised by short, rounded, advanced subdorsal fins, and a short internal horny style.

Sepiolite. A hydrated silicate of magnesia, with nearly the same composition as Talc. It is the Meerschaum of some authors, and the Magnesite of others.

Sepium. The bone or internal shell of the cuttle-fish.

Sepoy (a corruption of the Indian word sipahi, *soldier*). The designation of the native troops in her majesty's Indian army, formerly in the service of the East India Company. They were so called as early as 1708 (Mill's *British India*, book iv. ch. 1.), although at that period they do not seem to have been disciplined in the European fashion, nor, indeed, until long after other European powers had set the example. The first sepoys who were raised and regularly disciplined by the English seem to have been carefully chosen either from among the Mohammedan portion of the population, or from among the higher castes of Hindus, a considerable proportion of the latter being Rajpoots, the most warlike of Indian races; but the necessities of the service subsequently introduced a greater mixture in their ranks. The character of the sepoys as soldiers was always the subject of much discussion; they have justly been celebrated for excellent qualities; as, for instance, patience and fortitude under difficulties and privations. But, on the other hand, if we analyse the account of the wars in which they have been employed, we shall find that they seem to have possessed passive rather than active courage; for instance, that in line they remained steady under fire: in a broken or close country, however, where skirmishers and small detachments are necessarily most employed, they were found wanting. The mutinies of Vellore in 1806 and Barrackpore in 1825 should perhaps have shown that the sepoys were not to be trusted in the same manner as European troops; and the Indian mutiny of 1857-8 ultimately led to the disbandment of a great portion of the native army. The Bengal sepoys, it is well known, had been in a state of ill-discipline for a long time before the outbreak; and the absence on various employments, civil as well as military, of a large number of the officers, prevented their being properly controlled. The Madras sepoys, with few exceptions, remained firm to their trust; and their fidelity did much towards saving the Indian empire. Under a new régime it is to be hoped that many sepoys will never again be collected together without a sufficient force of European troops to hold them in check. It is probable that a certain number of native troops must always be employed in India to perform duties which the climate forbids to Europeans without great risk. (Kaye's *History of the Sepoy War.*)

Seps (Lat.; Gr. σήψ, from σήπω, *to putrefy*, in reference to the effects of its bite). The name of a genus of Saurian reptiles, which have a long round serpentiform body, and four very short legs, each terminated in the common seps (*Seps chalcides*) by only three toes.

Septaria. Flattened calcareous nodules found in clay, chiefly in the London clay and Kimeridge clay, but also in the Lias and elsewhere. They are segregations of the more calcareous portions of a deposit of marly clay, and are not unfrequently (perhaps always) collected round some organic body. Once formed, probably while the mass was wet, they have cracked in drying, and the cracks are filled up with crystalline carbonate of lime or calc spar. They are sometimes cut across and polished for ornamental purposes. Their chief use is to grind down, after burning, into hydraulic lime, for which their mixture of argillaceous matter with limestone makes them very valuable.

September (Lat. from septem, *seven*). This month, so called from its being the seventh month in the Roman year, established, as is supposed, by Romulus, is the ninth month in the so-called calendar of Numa. Several of the Roman emperors gave names to this month in honour of themselves; but, unlike the months of July and August, the name of September has outlived every other appellation.

Septembrists. The name given to the agents in the dreadful massacre which took place in Paris on September 2, 1792, during the French revolution. The numbers that perished in this massacre have been variously given; but the term has become proverbial throughout Europe for all that is bloodthirsty and malignant in human nature.

Septemviri Epulonum (Lat.). Certain priests in ancient Rome were so called, whose duty consisted in preparing the sacred feasts at games, processions, and on other solemn occasions. They were assistants to the *pontifices*, certain of whose privileges, such as the right of wearing the *toga prætexta*, they enjoyed. Their number was raised from three to seven, it is supposed, by Sylla.

Septennial Act. The stat. 1 Geo. I. sess. 2 c. 38, providing that the parliament which passed it, and all parliaments that should thereafter be called, might respectively have continuance for seven years, unless sooner dissolved.

Septentrional (Lat. septentrionalis). A word sometimes used to denote the northern portions of the globe. By the name septentriones, the Latins designated the seven stars which form the constellation of the Great Bear. For the real meaning and history of the term, see RISHIS.

Septic (Gr. σηπτικός, *making rotten*). A term applied by the old chemists and physiologists to certain substances supposed to promote putrefaction.

Septicidal (Lat. septum, *a hedge*, and cædo, *to cut*). In Botany, that mode of dehiscence in which the fruit is resolved into its component carpels, which split asunder through the dissepiments.

Septifragal (Lat. septum, and frango, *to break*). In Botany, that mode of dehiscence in fruits in which the backs of the carpels separate from the dissepiments, whether formed by their sides, or by expansions of the placenta.

Septuagesima (Lat. sc. dies, *the seventieth day*). In the Ecclesiastical Calendar, the third Sunday before Lent; the first Sunday in Lent being termed Quadragesima (fortieth), the three preceding ones Septuagesima, Sexagesima, and Quinquagesima.

Septuagint (Lat. septuaginta, *seventy*). The Greek translation of the Old Testament made at Alexandria for the advantage of the Jews of Egypt, who had lost the use of the Hebrew language. According to the old tradition, this version was the work of seventy-two interpreters, who were shut up in separate cells by the command of Ptolemy Philadelphus, and there completed the whole translation alone, in which, upon examination, they were all found to agree to a letter—a prodigy which established the inspiration of the work. It is supposed, however, by modern critics, that this version of the several books is the work not only of different hands, but of separate times. The authority of the Septuagint, as compared with the Hebrew text, from which it differs in many points, has been the subject of much controversy. It is from this version that the authenticity of the Apocrypha, which are not found in the Hebrew, is asserted by Roman Catholic writers. The quotations of the Old Testament which are found in the New are for the most part given in the words of the Septuagint.

Septum (Lat. septus, part. of sepio, *I fence in*). In Anatomy, the plate or wall which separates from each other two adjoining cavities; as the septum transversum, or diaphragm, between the chest and the abdomen; the septum narium, between the two nasal passages; the septum ventriculorum in the brain; and in the heart, &c. The partitions of chambered shells are also called *septa*.

SEPTUM. In Botany, any partition separating a body into two or more cells in a direction parallel with the longer axis. Partitions parallel with the shorter axis are called *phragmata*.

Sepulchre. [TOMB.]

Sepulchre, Church of the Holy. By this name is commonly known the church at Jerusalem, of which the Greek and Latin communions each have partial possession, and which, according to the present local tradition, stands on the site of the church erected by Constantine, near the tomb in which the body of Christ was laid in the interval between the Crucifixion and the Resurrection. This popular tradition involves the maintenance of three propositions: (1) that the present building stands on the site of a previous church which had been destroyed; (2) that the church so destroyed was the building erected by Constantine; (3) that the tomb over or near which it was built was the actual sepulchre in which the body of Jesus was laid.

On this proposition has arisen a complicated controversy, of sufficient importance to justify our giving a summary of the arguments employed on both sides.

Denying the three propositions involved in the current tradition, Mr. Fergusson maintains that the church built by Constantine was not on the site of the present sepulchre, but is the building commonly known as the mosque of Omar. The grounds on which he bases this conclusion are chiefly architectural and topographical, while he also holds that the documentary evidence is substantially on his side.

A thorough familiarity with Mohammedan buildings in India and other eastern countries had convinced Mr. Fergusson that the circular shape of the mosque of Omar was proof conclusive that it was built not as a mosque, but as a tomb, the essential definition of a mosque being that it is a wall at right angles to the direction of Mecca, whereas the round form is common to Mohammedan and other tombs. But the mosque of Omar has four entrances facing the cardinal points of the compass, the principal entrance facing south, so that a worshipper would enter by turning his back on the kaaba. In the absence, however, of any tradition that Omar or any Mohammedan saint had been buried under the dome, the conclusion was forced upon him that this was a Christian sepulchral building, and that it could only be the edifice raised by Constantine over what he believed to be the tomb of Christ. Laying down the general position, that in every instance of conflicting evidence an appeal to style is at once allowed to override the most minute and circumstantial written testimony, Mr. Fergusson institutes a comparison between the mosque of Omar and buildings ranging from the third to the seventh or eighth centuries, and concludes that the Khubbet-es-Sakrah (or Dome of the Rock, or mosque of Omar) is later in date than the palace of Diocletian at Spalatro, but earlier than Justinian's church of St. Sophia at Con-

stantinople, and that the building known as the Golden Gateway is a work of the same age. It is true, the Moslem tradition since the Crusades assumes that the Dome of the Rock covers the site of the altar or holy of holies of Solomon's temple; but as neither the Bible, nor the Talmud, nor Josephus mentions a rock as connected with either the altar or the holy of holies, the tradition is worthless, while it may also be shown that the rock Sakrah was altogether outside the temple area, and could not have sustained the altar under any circumstances. If, on the other hand, it be said that the presence of classical or late Roman details in the Dome of the Rock may be accounted for by the employment of columns and capitals taken from ruined buildings, Mr. Fergusson answers that, if it were a portico of four or six pillars, with twenty or thirty feet of entablature, anything might be assumed, but confining the argument to the aisle screen alone, eight piers, sixteen pillars, and 400 feet of entablature mitreing at all sorts of angles, and fitting everywhere without any appearance of contrivance or adjustment, present a phenomenon not to be explained away, while the building is just such an one as we should find emanating from Constantine's order that 'the church may surpass all others in beauty.'

These conclusions Mr. Fergusson holds to be generally borne out by historical documents. Thus Eusebius, he affirms, speaks of a round church as built over the sepulchre, and distinct from the great basilica which adjoined it. These buildings, were, it is said, destroyed by fire during the sack of the city by the Persians in 614; but this fire, he thinks, has been as useful to those who adhere to the current tradition as the conflagration at Wolf's Crag was to Caleb Balderstone, the damage done in both cases being much the same. The great proof of this is the fact that a simple monk, named Modestus, restored the whole to their pristine magnificence without means or money. And again, the history of the Mohammedan conquest proves that the Sakrah is not the rock of Omar, the position of which is clearly marked out by that of the gate of Mohammed as being within the substructure of the temple; and, finally, Arculfus, a pilgrim of the seventh century, mentions (1) the Anastasis or round church, containing the sepulchre; (2) the square church of St. Mary; (3) the large church of Golgotha; (4) the Basilica or Martyrium, built by Constantine with great magnificence.

If, then, this is a true account of the facts, a transference of the site took place at some time or other subsequent to the conquest by the Saracens. Of this transference there is no record, but the fact is as easily explained as the transference of the Santa Casa to Loretto, and may have been caused by the envy of the Moslems, who, after the capitulation of Omar had fallen into desuetude, cast longing eyes on the Dome of the Rock, either because they were offended that the Christians should possess a more splendid building than themselves close to their own mosque El Aksah, or because they coveted the custody of the tomb of Christ, whom they looked upon as the greatest of prophets next after Mohammed. When, in the eleventh century, the Christians crept timidly back to Jerusalem, they built themselves a church in their own quarter of the town, and to this church were gradually transferred the traditions of the sites from which they had been dislodged.

If any objection be made to this theory on the score of the character in which the inscriptions round the dome of the Sakrah are written, Mr. Fergusson meets it by remarking that, although a writing in Coptic characters runs round the dome, one short paragraph in it is said to contain the name and date of the builder; and as it is allowed that either the name Al Mamoun, or the date, 72 Heg., A.D. 691, is a forgery, no argument can be based upon it, while his own opinion remains that, notwithstanding the evidence of the Coptic character of the writing, the whole is of the time of Saladin. (*Essay on the Ancient Topography of Jerusalem*, 1847; *Notes on the Site of the Holy Sepulchre at Jerusalem*, 1861; *The Holy Sepulchre at Jerusalem*, being Two Lectures delivered at the Royal Institution, 1865.)

In opposition to these arguments and conclusions of Mr Fergusson, it is maintained that the tradition which claims for the present Church of the Sepulchre the site of the building raised by Constantine has no necessary connection with the genuineness of the tomb said to have been discovered by Constantine, and that this part of the question may accordingly be dismissed. And, further, it is argued that the architectural evidence cannot in all cases be received with the unhesitating reliance which Mr. Fergusson places in it; that there are or may be special reasons for distrusting it when we are dealing with the work of a people who, having no style of their own, are in the habit of employing the architects and builders of conquered nations; that in the case of Waltham Abbey the documentary evidence is neither undisputed nor conclusive, as Mr. Fergusson takes it to be; that the architectural evidence is not in this case received, in the truth of the documentary evidence, as proving that the whole of the present building was erected after the Conquest; and that we have no right, as Mr. Freeman argues (*Gentleman's Magazine*, February 1861), to admit without evidence such an hypothesis as that of Mr. Fergusson, who suggests that the ecclesia in which Harold was first buried was a round church which has utterly perished.

In support of his theory, Mr. Fergusson has adduced the basilica of San Clemente at Rome, originally erected in the fourth century, and of which he feels convinced that we have now the original apse with its ornaments, except the cross in the centre, which is an interpolation of the thirteenth century, the nave belonging perhaps to the eighth, and the choir to the ninth century. To this it is replied that the recent

discovery of the lower church of San Clemente, the frescoes of which, belonging in some instances to the tenth and eleventh centuries, show that this church was in use long after it was supposed to have been superseded by the existing church, compels us to assign to the latter a date which sweeps away Mr. Fergusson's theory about the apse of the existing church with its decorations, inasmuch as the lower level of the previous building precludes the idea that that apse is a remnant of the original building.

On the subject generally, it is maintained by Professor Willis, the Rev. G. Williams, Count de Vogüé and others, that the reputed Sepulchre contains indubitably a rock-hewn tomb, whether the Sakrah be likewise a tomb or not; that the building in which it stands was demolished first by the Persians, and more systematically by the order of Hakem, when every effort was made to destroy the sepulchre by iron hammers and fire, while the Khubbet-es-Sakrah has escaped uninjured, and the rock exhibits no sign of having undergone such treatment. It is further argued that the language of Eusebius does not warrant the existence of any round church over the holy sepulchre, as he merely says that Constantine adorned the cave, as such, with choice columns and abundant decorations, and that the cave thus adorned opened into a large hypæthral court, surrounded by cloisters on all sides excepting the one facing the entrance to the cave, the basilica being on this side, precisely facing the cave and looking east; that the words of Eusebius leave no room for thinking that the sepulchre was contained in a separate building, and that the title, τὸ μαρτύριον τῆς ἀναστάσεως, applied to the basilica set aside the distinction drawn between the dome of Omar as the Anastasis and the Basilica as the Martyrium. Mr. Fergusson, it is urged, finds two buildings, the mosque of Omar, and the Golden Gateway, of which he takes one to be the actual sepulchral church, and the other to be the entrance to the atrium of the basilica; and his restored plan, formed from these data, exhibits a basilica, whose western end, so far from being precisely opposite to the sepulchre, does not even face any side of the Khubbet-es-Sakrah whatever. Again, the mosque of Omar is a rotunda; but the present church of the sepulchre furnishes evidence that the former building on the same site was not a rotunda, more than half the aisle of the present rotunda being bounded by a concentric wall, in which are placed three small apses, one at the west end, the others on the north and south. If the design of the original church had been round, the north and south apses must have had their axes on the diametral line of the rotunda; but Professor Willis remarks that the line falls to the eastward of both these apses, and thus corroborates the description of Eusebius, who likewise speaks of the propylæa as opening upon the middle of the great market place. The east end of the present church still opens on a street of deserted bazaars; and as the Golden Gateway looks down immediately on the valley of Jehoshaphat, the theory of Mr. Fergusson is rendered, in the judgment of Professor Willis, 'ludicrously impossible.'

Further, it is urged that the form of the Khubbet-es-Sakrah proves only that the building was designed to preserve the rock which forms its area, and that this rock is reverenced by the Mohammedans for reasons not connected with the sepulchre of Christ; that the round church of Modestus, completed half a century before Abdal Malek commenced the mosque, if it be his work, may have suggested the form, while the Greek character of the details is evidence that it was not wholly or in great part built by Saracenic workmen; and that the dome is confessedly of pure Mohammedan architecture. It is also maintained that, while the Dome of the Rock exhibits no signs of the violence from which the church of the sepulchre is said to have suffered repeatedly, the words of Eusebius seem to state positively that the church of Constantine was built on a hill opposite to that on which the Jewish temple had stood, the *new Jerusalem* being a name employed by him and by Socrates to designate the Martyrium of the Anastasis itself; and that the language of Arculfus, who speaks of a round cabin cut out of a single piece of rock in the middle of the round church, containing a space large enough for nine men to stand and pray, seems to be not less unsuitable as the description of a rock projecting to a height varying from six to ten feet, and having a diameter of nearly fifty feet.

It is further maintained that the whole inscription running round the Dome of the Rock, with the exception of the one name of Al-Mamoun, is written in characters which were in use at the time of Abdal Malek, the real founder, but which had become obsolete long before the age of Saladin, to which the inscription is assigned by Mr. Fergusson; that the Mohammedans did not appropriate the building because it was built in honour of Christ; that the inscription which denies His divinity is no evidence of any supposition on their part that this building contained His sepulchre, and that, in fact, the Moslems, adopting the Gnostic notion that a phantasm was substituted at the Crucifixion, have no belief in the death of Christ, and hold the tomb of Christ in abhorrence as being the tomb of His betrayer.

Finally, it is maintained that all the architectural difficulties raised by Mr. Fergusson have been practically solved by recent discoveries of Count de Vogüé in Central Syria, which prove that the trabeate and arcuate construction characteristic of the Dome of the Rock, was the prevailing feature of the large churches in the province of Antioch, so late as the seventh century, and that these churches furnish the very type with which the builders of the Khubbet-es-Sakrah would be most familiar, and which they would naturally copy in the buildings which they were employed to erect whether

for their Christian or Moslem employers. (De Vogüé, *Les Églises de la Terre Sainte*; Williams, *Holy City*, including an *Architectural History of the Church of the Holy Sepulchre*, by Professor Willis; Robinson, *Biblical Researches in Palestine*; *Edinburgh Review*, October 1860, art. 'Churches of the Holy Land;' *Quarterly Review*, October 1864, p. 404, &c.

Sepulchre, Hospitallers of the Holy. An order of knighthood, originally instituted in Palestine, afterwards established in France by Louis VII., and united by Pope Innocent VIII. to that of Malta; but the order still continued to exist in France, and was taken under protection by Louis XVIII. in 1814.

Sepulchre, Regular Canons of the Holy. A religious order, instituted at Jerusalem. These canons were introduced also into France, Poland, Flanders, and England. The order was suppressed by Innocent VIII., and its revenues passed ultimately into the hands of the knights of St. John of Jerusalem.

Sepulture, Rites of. This term denotes literally the ceremonies performed in depositing the bodies of the dead *in the earth*; but the expression is applied in a more extended signification to all funeral ceremonies. The three chief modes of treating the dead that have prevailed from the earliest ages down to the present times are burning, interment, and embalming. Among the Greeks and Romans, both incremation and interment prevailed, though the former was by far the most frequent. The practice, peculiar to the Egyptians, of embalming their dead, has been noticed under MUMMY; and the Indian custom of immolating women on the funeral pile of their husbands will be found under SUTTEE. The practice of interment has been adopted by all the nations that have embraced Christianity. [CEMETERY.]

Sequence (Lat. sequentia, *a following*). In Music, a similar succession of chords ascending or descending diatonically.

Sequestration (Lat. sequestratio, from sequester, *a go-between* or *mediator*). In English Law, a species of execution for debt in the case of a beneficed clergyman, issued by the bishop of the diocese on the receipt of a writ to that effect. The profits of the benefice are paid over to the creditor until his claim is satisfied. *Sequestration* is also, in Chancery, a process for enforcing the decrees or orders of the court by seizure of the property of a person guilty of disobeying them.

SEQUESTRATION. In Scottish Law—1. A species of diligence (i.e. a process), used where two or more creditors are in competition for the property of a land estate, the owner of which is in insolvent circumstances; or where the right to a land estate is the subject of litigation. In these cases the court may, on application, sequestrate the rents, and employ a factor to collect them. 2. Sequestration is also the process whereby the whole estate, both heritable and movable, of a bankrupt, is distributed equitably amongst his creditors. It is granted on application to the court of session by the bankrupt, with the concurrence of one or more creditors, or on their application, and on citation of the bankrupt. It is analogous to a bankruptcy in English law.

Sequin (Ital. zecchino; from zecca, *a mint*). The gold pieces of Venice were originally so called; afterwards the name was extended to other gold coins in use in the Mediterranean, as those of the pope, the sultan, Florence, and Genoa. [MONEY.]

Sequoia. A genus of *Coniferæ* from North-Western America, consisting of two species only, and closely allied to *Sciadopitys*, being distinguished from it principally by its peltate scales without bracts, and five to seven seeds. *S. sempervirens*, the Redwood of the timber trade, extends from Upper California to Nutka Sound. It attains gigantic dimensions, being frequently more than 300 feet high, imparting to the woods of its native country a peculiar character—'something,' Douglas tells us, 'which plainly shows that we are *not* in Europe.' The Redwood has long been an inmate of our gardens, and principally differs from the *Wellingtonia* in having linear rather obtuse leaves whitish beneath.

S. Wellingtonia (the *Wellingtonia* of our gardens, and the Big or Mammoth-tree of the Americans) was at first thought to be confined to a single spot, the so-called Mammoth Grove of Calaveras in Upper California; but it has since been found in the Mariposa and Frezno Groves, and in various other parts of the Sierra Nevada, though nowhere attaining such a height as in the spot where it was first dis-

Sequoia Wellingtonia.

covered, in June 1850, by an American hunting-party. The tallest tree of the Mammoth Grove, stripped of its bark for the purpose of being exhibited, was 327 feet high, and at the base was 90 feet in circumference. The greatest dimensions seem to have been attained by a tree which was found broken at a height of 300 feet, and which measured at that place 18 feet in diameter. Considering that it was 112 feet in circumference at the base, and tapered regularly to the point where broken,

it is calculated to have been when in the fulness of its growth 450 feet high. It was at first thought that these trees might be 3,000 years old, but that estimate has since been reduced, by actual counting of the concentric rings, to about 1,100 years. This fine hardy evergreen tree was introduced into Europe in 1853, and stands our climate remarkably well. The wood when first cut is white, but ultimately turns mahogany colour.

Seraglio. An Italian corruption of the oriental word *serai.* The palace of the Turkish sultan in Constantinople is thus designated by European writers. The principal gate of the seraglio is the Babi Humayun, or Sublime Gate, whence the ordinary title of the Turkish government is derived.

Seraphim, or **Jesus, Order of the.** An ancient Swedish order of knighthood, instituted in 1334; but dormant from the period of the Reformation until 1748. The number of knights, besides the king and members of the royal family, is limited to twenty-four.

Seraphine. A name formerly used for the instrument now called the HARMONIUM.

Seraphs or **Seraphim** (Heb.). In the Angelic Hierarchy of the Jews, the angels of the highest rank. They are represented as surrounding the throne of God, whose messengers they are, and as being more immediately inspired with the Divine love, which they communicate to the inferior inhabitants of heaven. They are almost invariably spoken of in connection with the *cherubim,* whom they resemble both in rank and attributes.

Serapis. An Egyptian deity. The image and worship of this god were brought from Sinope in Pontus to Alexandria, in the last year of Ptolemy Soter, in consequence, it is said, of a vision of Ptolemy I.

The magnificent Serapeum, or temple of this god, at Alexandria, one of the most splendid of pagan temples, was destroyed by order of the emperor Theodosius during the struggle between the Pagan and Christian population of the city, A. D. 390. (Milman's *History of Christianity,* book iii. chap. viii.)

Serasquier. The name given by the Turks to the commanders-in-chief of their armies. It is compounded of two Persian words, signifying *head of an army.*

Serenade (Span. serenata, from Lat. serenus, *clear*). This word signified originally music performed in the open air on a *serene* evening; but is now universally applied to a musical performance by gentlemen under the windows of ladies whom they admire. This practice, which was formerly very general in Spain and Italy, has latterly fallen greatly into disuse in these countries; but it is still very common in the German university towns, where the students are in the habit of assembling in the evening under the windows of a favourite professor, and offering him a musical tribute.

Serene, Serene Highness, Serenity (Ger. durchlaucht). Titles of courtesy in European etiquette, of considerable antiquity. Before the dissolution of the German empire, Serene and Most Serene Highness were the appropriate addresses of princely houses holding immediately of the empire. Since that period the rules of princely etiquette have become more uncertain; but it appears to be the general principle that these titles belong of right to members of the families of sovereign houses in the confederacy, and also to members of ci-devant sovereign houses *now mediatised*: and that sovereign princes can moreover concede these appellations to princes not sovereign within their own dominions, yet not so as to give them a title to it out of them. But the distinctions as to the mode in which these titles are to be employed in addressing superiors, equals, and inferiors, are extremely complicated.

Serf (Lat. servus, *a slave*). When the mass of a community, being engaged in agricultural pursuits, hold land at fixed labour rents, and are tied to the soil, or only released from it by an agreement, capitation tax, or formal manumission, such persons are called *serfs*; and by a natural analogy, when legal enactments tend to bind labourers to a particular locality or calling, persons are accustomed to speak of such a population as serf. A serf differs from a slave by the fact that his amount of labour is fixed, and is ordinarily given in compensation for land—the remainder of the produce, after his service is given, or a money commutation for it paid, being his own property, whereas the slave has no property and can be taken away from the soil and disposed of at the pleasure of his owner. Serfdom, under the name of villenage, was slowly extinguished in England before the Reformation; it lingered in Scotland till the close of the last century, when the last relics of it were finally abolished. In the Russian social system, one of comparatively late origin, the mass of the community were serfs; but within the last few years serfage has been put an end to in that country. [OBROK; RYOT; SLAVERY; VILLEIN.]

Serge (Fr.; Span. xerga). A cloth of quilted woollen, extensively manufactured in Devonshire and other English counties.

Series (Lat. from sero, *I join together*). An Algebraical expression whose successive terms are formed according to some general law. According as the number of its terms is limited or unlimited the series is said to be finite or infinite. With respect to series, the principal questions which arise are how to develope a given finite expression in a series, how to find the expression or *generating function,* from which a series has originated, how to express any *general term* as a function of the number *n* of that term, and how to find the sum of any given number of terms or the limit to which, in the case of a convergent series, that sum approaches the greater the number of terms added. [CONVERGENT AND DIVERGENT SERIES.] The most effective way of developing an expression in a series is furnished

by the differential calculus (Taylor's *Theorem*), whilst the calculus of finite differences enables us frequently to ascend from the general term to the sum of any number of terms.

Series derive their names from the laws which govern the formation of their successive terms. Thus, an *arithmetical* series is one whose consecutive terms have a common difference; a harmonic series one of which every three successive terms are in a harmonic proportion. A *geometric series* is one every term of which has a constant ratio to the preceding one; it belongs to the family of *recurring series* in which each term is a constant function of one or more preceding terms.

The theory of series constitutes an extensive and very important branch of mathematics. Amongst the numerous works on the subject may be mentioned Euler's *Introductio in Analysin Infinitorum* and *Calculus Differentialis*, Cauchy's *Cour d'Analyse* and *Exercices de Mathématiques*, Catalan's *Traité Élémentaire des Séries*, and *Penny Cyclo.* art. 'Series.'

Serjeant (Fr. sergent, from Lat. serviens). A non-commissioned officer in the army, of higher rank than a corporal. There are serjeants and staff-serjeants; among the latter are serjeant-majors, quartermaster-serjeants, &c. The regimental serjeant-major acts as assistant to the adjutant. There are colour-serjeants in infantry regiments, troop serjeant-majors in cavalry, and battery serjeant-majors in artillery. There are a certain number of serjeants to each company, troop, or battery, and they have general duties of supervision.

Serjeant. Serjeant-at-law is the highest degree in the common law, and all must proceed through this degree before attaining the dignity of judge. In practice, however, the two dignities are usually conferred simultaneously. The Court of Common Pleas was formerly open to serjeants only for the purpose of pleading, while the court was sitting in *banc*, they having been anciently the only advocates recognised in the common law. This exclusive privilege was attempted to be taken away in 1834, and for five years the court was thrown open. But, after solemn argument, it was decided by the privy council that this enlargement was unwarranted, and the former practice again prevailed until the monopoly of the serjeants was finally abolished and the court thrown open to the bar at large by stat. 9 & 10 Vict. c. 52. Serjeants-at-law are now made by the royal writ, commanding them to take their degree. No precise time seems necessary to permit a barrister to become a serjeant. This office is seldom now assumed by practising barristers except by those who practise mostly in the criminal courts, and who wish to be able to hold leading briefs for the defence of prisoners without the necessity, in every case, of obtaining a license to appear against the crown, which as queen's counsel they would be obliged to do. [Queen's Counsel.] (Serjeant Manning's *Serviens ad Legem.*)

Serjeant, The Common. An officer of the corporation of the city of London, discharging some judicial functions.

Serjeant, King's or **Queen's.** One or more of the serjeants-at-law, whose presumed duty is to plead for the crown in causes of a public nature, as indictments for treason, &c., but the title is now merely honorary.

Serjeants-at-Arms. Officers whose duty is to attend the person of the sovereign, or of the lord high steward when sitting in judgment on a traitor, &c. They formerly formed a sort of body-guard, whose number was restricted by an ancient law (13 Rich. II.) to thirty, but their functions in this capacity have long become obsolete. Two serjeants-at-arms are allowed by the sovereign to attend at the houses of parliament during their sittings, and each has a deputy. In the House of Lords, the practical maintenance of decorum below the bar, near the throne, and in the gallery, devolves upon the gentleman and yeoman usher, with their assistants, so that, 'the serjeant-at-arms attending the House of Lords' has less conspicuous duties to perform than those which devolve upon 'the serjeant attending the House of Commons:' both, however, execute the commands of the house to which they belong, as regards the apprehension or custody of all persons committed by order of parliament. In the House of Commons, the serjeant-at-arms is an officer of considerable importance, enjoying large emoluments, assisted by a deputy and several subordinate officers. During the sittings of the house he occupies a chair below the bar, and directs a large proportion of the arrangements connected with the maintenance of order in the approaches to the house and the offices adjacent. He is at once the executive and the ceremonial officer of the lower house; but his discretionary powers are not extensive, for almost all his more important duties are performed under the immediate direction of the house itself, communicated through the speaker. The office is usually held by a gentleman of the military profession, seldom under the rank of a field officer.

Serjeanty, Grand and Petty. In the English Law of feudal tenures. Tenure by grand serjeanty was where the tenant held land of the king by service, to be performed in his own person, in his wars, &c.; such as to bear a banner or spear, or to assist at his coronation. Tenure by petit serjeanty was where the owner was bound to contribute some small thing towards military service, &c.; such as a sword, dagger, bow, or spear. Tenure by grand serjeanty was preserved by stat. 12 Ch. II., which abolished the other feudal tenures, and still subsists in some cases. Tenure by petit serjeanty is not referred to in stat. 12 Ch. II.; and the Blenheim and Strathfieldsaye estates, bestowed by the nation as the reward of public services, are held of the crown by this tenure, the dukes of Marlborough and Wellington being each bound to render a small flag annually.

Sermon (Lat. sermo, *a discourse*). In Ecclesiastical usage, the sermon or homily as a portion of the communion service is said to be of remote antiquity. This ancient custom fell into partial disuse during a great part of the middle ages. The Homilies of Ælfric, archbishop of Canterbury in the tenth century, were long used in the English church; but these became antiquated; and in the year 1281 (Palmer, *Orig. Liturg.* vol. ii. ch. iv.) preaching seems to have been generally omitted. In that year, Archbishop Peckham ordered, in his Constitutions, that four sermons should be delivered during the year. But for some time prior to the Reformation preaching was again coming more into use; and the publication of homilies by authority went far towards restoring the ancient practice. [HOMILY.]

Seron (Span.). A buffalo's hide, used for packing drugs and other articles.

Serosity (Lat. serum). The liquid which exudes from the serum of the blood when it is coagulated by heat. It is water holding some of the salts of the blood and a trace of albumen in solution.

Serpens or **Serpens Ophiuchi.** In Astronomy, one of the ancient constellations in the northern hemisphere.

Serpent (Lat. serpens, part. of serpo; Gr. ἕρπω, *I creep*; SARPEDON). A musical brass wind instrument, serving as bass to the horns or cornets. It is most generally covered with leather, and has three parts: a mouthpiece, neck, and tail. The compass is two octaves, produced with six holes stopped with the fingers. The serpent is chiefly used for accompanying Gregorian music in Roman Catholic churches. It is rarely employed in the modern orchestra.

SERPENT. In Mythology, the serpent played an important part. By some nations it was regarded as the emblem of cunning, deceit, and wickedness (compare the narration of the fall of man in Genesis with the Persian myth of Ahriman and Ormuzd); by others, such as the Egyptians and Phœnicians, it was looked upon as a good genius; while by the Greeks and Romans, it appeared under a variety of symbolic representations. With the latter, the serpent was the well-known emblem of the healing art; and in the present time a serpent with its tail in its mouth is regarded as an emblem of eternity. The serpent appears also in the Scandinavian mythology. [DRAGON; VRITRA.] In the early ages of the Christian church, a sect of the Gnostics also worshipped the serpent, whence they were called OPHITES. Dr. Donaldson identifies the serpent mentioned in Genesis iii. with the PHALLUS. (Jashar, *in partem primam Commentarius*, p. 47.)

SERPENT. In Zoology, a general name for the species of the order *Ophidia*.

Serpents are divided into spurious, or *Pseudophidians*, and true, or *Ophidians* proper. The *Pseudophidians*, although presenting the well-marked external characters of the order, retain an imperfect pelvis, a small sternum, scapulæ, and coracoids or clavicles, hidden beneath the skin; whereby, as well as in the structure of the skull, they approach the Saurian order. The common blind-worm (*Anguis fragilis*) is a native representative of the *Pseudophidian* family.

The true serpents have neither sternum nor vestige of the scapular arch: they have no third eyelid, nor tympanum; but the auditory ossicle exists beneath the skin, and its handle passes behind the tympanic bone. Several species retain a vestige of hind-limbs, which in some even shows itself externally in the form of a small hook. The chief subdivisions of the true *Ophidians* are: the *Amphisbæna*; the *Typhlopes*; the *Roles* (*Tortrix*); the *Boas*; the *Pythons*; the *Colubers*; the *Acrochords*—all which tribes are non-venomous. The *Pseudoboas*, *Rattlesnakes*, *Trigonocephali*, and *Vipers* are the venomous tribes; and are distinguished by having the superior maxillary bones short and movable, supporting fewer teeth than in the non-venomous serpents, and having the first of the short series larger than the rest, sometimes the only conspicuous fang, and traversed by the duct of a poison-gland, around which duct the tooth is, as it were, longitudinally folded, so as to appear perforated by a canal. The last tribe of true serpents includes the *Hydrophides*, or sea-snakes, which have likewise a poison-gland and duct, the latter being enclosed by the last instead of the first of the maxillary series of teeth. The tail of the sea-snakes is flattened vertically, and forms their chief organ of swimming. No species of this family has yet been discovered which exceeds ten feet in length.

The remains of an extinct genus of serpents (*Palæophis*), indicating species of from ten to twenty feet in length, have been discovered in the Eocene tertiary formations in Suffolk, Kent, and Sussex. (Prof. Owen's paper in the *Geol. Trans.*, second series, vol. vi. p. 209.)

Serpentarius. One of the ancient northern constellations, represented on the globes by the figure of a man grasping a serpent (*serpens*) in his hand. [CONSTELLATION.]

Serpentary Root. The root of *Aristolochia Serpentaria*.

Serpentine. A hydrated silicate of magnesia found disseminated in rocks, or forming large rock-masses, as in the Lizard district in Cornwall. The stone from this locality as well as that from Portsoy in Banffshire is much used for ornamental purposes instead of marble, being soft and easily worked, and susceptible of a fine polish. The name has reference to its spotted and veined appearance, like that of a serpent's skin.

SERPENTINE. A cannon of the fifteenth and sixteenth centuries, somewhat larger than the culverin. The name first appears in France about 1450, and in England a few years later. [CULVERIN.]

Serpigo. [RINGWORM.]

Serpuleans (Lat. serpo, *I creep*). The name of a family of Cephalobranchiate Anneli-

dans, inhabiting cylindrical and tortuous calcareous tubes; generally parasitic on shells.

Serradilla (Port.). A fodder plant not much cultivated in this country. It is a small Leguminous annual, the *Ornithopus sativus* of botanists.

Serrate (Lat. serratus, from serra, *a saw*). In Zoology, when a part is cut into teeth like a saw, or is armed with teeth whose sides are unequal.

Serricorns (Lat. serra, *a saw*; cornu, *a horn*). The name of a family of Coleopterous insects, comprehending those which have serrated or saw-shaped antennæ.

Sertularia (Lat. sertum, *a wreath*). The name of a genus of compound tubular Polypes; restricted, in modern zoology, to those species in which the cells are arranged on two sides of the stem either opposite or alternate.

Serum (Lat. *whey*). In Anatomy, the constituent of the plasma, or liquor sanguinis, which remains after the separation and coagulation of the fibrin. Serum contains a large quantity of albumen, and coagulates at a temperature of from 160° to 170°.

Serval. A species of spotted cat (*F. serval*, Cuvier) found at the Cape of Good Hope. The species there represents the lynx of Europe and the ocelots of South America.

Servetists. In Ecclesiastical History, a name which has sometimes been given to Unitarians, who hold the simple humanity of Christ; from Michael Servetus, a celebrated professor of those opinions, who was burnt to death at Geneva, by the orders of the magistracy of the republic, under the influence of Calvin, in 1553.

Servile. A Spanish political nickname; applied, in the first instance, to those who opposed the changes advocated by the liberal party in the cortes of 1808 and the following years.

Servites (servants of the Blessed Virgin). A religious order, instituted in Tuscany in A.D. 1233, under the rule of St. Augustin. The monks wore a black habit, in commemoration of the widowhood of the Virgin. (Mosheim, cent. xiii. part ii.)

Servitor (Lat. from servio, *I serve*). An undergraduate, who is partly supported by the college funds, is so called at Oxford. The servitors at Oxford correspond to the sizars at Cambridge.

Servitude (Lat. servitudo). In the Civil Law, servitude is divided into real or predial, mixed, and personal: the first being the subjection of an inheritable thing to certain duties or services towards another inheritable thing; the second that of an inheritable thing towards a person; the third, that of a person towards a person or thing, i.e. slavery, whether by dependence on a person or on the soil. The word *servitude* is equally applicable to the duty or burden, and to the right of exacting it: e.g. the right of way which A enjoys on the land of B, and B's liability to permit that right to be exercised, are both designated by the term *servitude*; the first active, the latter passive. Real servitudes are numerous, and fall into several classes or divisions. They are, for example, either *visible*, such as the right to light and air, sewers, &c., or *latent*, such as the right of way, right of drawing water, &c., which appear only when they are exercised. They were also divided by the Romans into urban, which affected dwellings in the city; and rustic, appertaining to land and farm building. Of mixed servitudes only three species were recognised by their writers on jurisprudence—usufruct, use, and habitation.

Servitude, Domestic. [SLAVERY.]

Servius Tullius. As the name of Romulus, the first of the traditional kings of Rome, has been included in the list of mythical personages noticed in this work, the interests of historical truth seem to require the admission that the last of the Roman kings is scarcely less mythical than his predecessors. The history of Servius is made up either of prodigies and marvels, or of plausible fictions of the kind which De Foe turned to such good account in his life of Robinson Crusoe. In one version, Servius is the son of a god, born of a slave named Ocresia; soon after his birth his mother saw his head enveloped in flames; when she awoke him the fire was extinguished. Niebuhr rejects this story as a mere contrivance to account for his name, which, he affirms, has nothing to do with slavery, but denotes a child born (sero, *late*) in the *evening*, as Manius means one born (mane) *in the morning*. Another account makes him the posthumous son of a chieftain slain in defending Corniculum against Tarquin. The emperor Claudius, on the other hand, in a speech preserved on a brazen tablet at Lyons, asserted that Servius was not a Latin at all, but an Etruscan, his real name being Mastarna; that he came to Rome with Cœlius Vibenna, and, settling with him on the Cœlian hill, changed his name to Servius Tullius. But Cœlius is the mere eponym of the hill which bears the name, as Orchomenos and Phigaleus are mere eponyms of Arcadian towns; and we have no means of knowing whence the emperor Claudius derived his information, nor is there any ground for believing that the Etruscans possessed an authentic historical literature. The legend in Livy represents him as succeeding to the throne while quite a young man; but almost immediately he has children old enough to be married to the children of Tarquin. So, again, Servius is said to have been murdered by the second Tarquin when the latter was a young man; but if this Tarquin was, as he is represented, the son of Tanaquil, he must have been 70 years old when he became king on the death of Servius, 95 when he was expelled, and 110 at his death. The story of his murder is a topographical legend to account for the name of the Vicus Sceleratus or the Accursed Street. This tale, in the belief of Niebuhr, formed part of a great epic poem lost before the time of

contemporary historians. Of such a loss we have no evidence whatever.

The element of plausible fiction comes in with the description of the Servian constitution. The contradictions which run through the whole account of the motives and character of the change are pointed out by Sir Cornewall Lewis, who admits the *possibility* that 'there may have been some historical ground, resting on a faithful official tradition, for connecting the name of Servius with an arrangement of the census; but there is no sufficient reason for believing him to have been the author of the matured and complex system which is presented to us as his work, or for supposing that the authorship of it is ascribed to him in any other sense than that in which Romulus is said to have founded the senate, Numa the ceremonial law, and Tullus Hostilius the law of the Fetiales.' (*Credibility of Early Roman History*, ch. xi. § 30.)

Sesamoid Bones (Gr. σησαμοειδής, *like sesame-seeds*). Small bones developed at or near the articulations of joints are so called by reason of their somewhat bean-like form. The term is also often given to the ossifications which are found in various tendons attached to the long bones. The *patella* or knee-cap is the largest of the sesamoid bones in man.

Sesamum (Lat.; Gr. σήσαμον). A genus of plants of the natural family *Pedaliaceæ*. They are supposed originally to have been natives of India; but are now cultivated in many countries. Their seeds, which are employed as an article of diet, yield an oil of a very fine quality, which, under the name of Gingelly oil, forms an extensive article of commerce in the East. When of good quality this oil is used for adulterating oil of almonds. All the species are annuals.

Sesbania (Arab. sesban). A genus of Leguminous plants consisting of shrubs or shrubby annuals dispersed over the tropics of both hemispheres, having pinnate leaves, the leaflets of which often possess the irritable nature of the well-known sensitive plant.

The Danchi of India, an erect slightly branched annual, is cultivated for its fibre, which, though coarse, is of great strength and very durable in water or when repeatedly wetted, and is consequently valuable for the ropes of fishing-nets, &c.; but it is not suitable for ship's cordage, as it contracts very much when wet.

Sesia (Gr. σής, *a moth*). The name of a genus of Lepidopterous insects.

Sesostris. A legendary or mythical king of Egypt. According to Herodotus, he was a son of Mœris, the eponym of the lake which bears the name, and reigned in the eleventh century B.C. According to Manetho, he is the third king of the twelfth dynasty, reigning in the fourth millennium B.C. In Diodorus, seven generations intervene between Mœris and Sesoosis, or Sesostris, of whom he professes to give an account more authentic than that of Herodotus. The dynastic schemes set forth by these and other writers are contradictory throughout; and Sir G. Cornewall Lewis (*Astronomy of the Ancients*, 347) especially notes 'that these discordant schemes all profess to be derived from the same authentic source. They cannot be reconciled by any legitimate method of criticism, and yet there is no satisfactory ground for preferring one to another. We are not entitled to assume that any one of our authorities was intentionally deceived by the priests, or that he reported or transcribed his information incorrectly. Having, therefore, no sufficient reason for selecting any one of these systems, we are compelled, by the laws of historical evidence, to reject them all.'

The stories told by Herodotus of Sesostris are assigned by other writers to kings who are named Sesoosis, Sesonchosis, Gosormies, &c. The process by which Egyptologists profess to reconstruct his true history is confessedly analogous to the method applied by Niebuhr to the early history of Rome. The Sesostris of Manetho is clearly the same as the Sesostris of Herodotus; but the dates differ by about 2,000 years. 'Bunsen,' remarks Sir G. C. Lewis, 'first takes a portion of him, and identifies it with Tosorthrus (written Sesorthus by Eusebius), the second king of the third dynasty, whose date is 5119 B.C., being a difference in the dates of 1,799 years, about the same interval as between Augustus Cæsar and Napoleon. He then takes another portion and identifies it with Sesonchosis, a king of the twelfth dynasty; a third portion of Sesostris is finally assigned to himself. It seems that these three fragments make up the entire Sesostris who in this plural unity belongs to the ancient empire; but it is added that the Greeks confounded him with Ramesses, or Ramses, of the new empire, a king of the nineteenth dynasty, whose date is 1255 B.C., who again was confounded with his father Sethos, which name again was transmuted into Sethosis and Sesosis. Lepsius agrees with Bunsen that Sesostris on the Manethonian list, who stands in the twelfth dynasty at 3320 B.C., is not Sesostris, but instead of elevating him to the third dynasty, brings him down to the nineteenth dynasty, and identifies him with Sethos, 1326 B.C., chiefly on account of a statement of Manetho, preserved by Josephus, that Sethos first subjugated Cyprus and Phœnicia, and afterwards Assyria and Media, with other countries farther to the East. . . . . We therefore see that the two leading Egyptologists, Bunsen and Lepsius, differing in other respects, agree in thinking that Sesostris is not Sesostris. . . . But here their agreement stops. One assigns Sesostris to what is called the old, the other to what is called the new empire, separating his respective dates by an interval of 3,793 years. What should we think if a new school of writers on the history of France, entitling themselves Francologists, were to arise, in which one of the leading critics were to deny that Louis XIV.

lived in the seventeenth century, and were to identify him with Hercules, or Romulus, or Cyrus, or Alexander the Great, or Cæsar, or Charlemagne, while another leading critic of the same school, agreeing in the rejection of the received hypothesis as to his being the successor of Louis XIII., were to identify him with Napoleon I. and Louis Napoleon?' (*Astronomy of the Ancients*, 370.)

Sesqui (Lat.). This prefix, applied to words, signifies one integer and a half; as sesqui granum, *a grain and a half*, &c. In Chemistry, this term is used to designate compounds in which an equivalent and a half of one substance are combined with one of another; thus, sesquicarbonate of soda is a salt composed of one equivalent and a half of carbonic acid with one of soda.

Sesqui. In Geometry, the expression of a ratio in which the greater term contains the less once, and leaving a certain aliquot part of the less over. Thus, if the part remaining is half the less term, the ratio is called *sesquialtera*; if the part remaining be a third of the less term (as in the ratio of 4 to 3), the ratio is called *sesquitertia*, and so on. These terms are nearly obsolete. *Sesquiduplicate*, however, sometimes occurs in modern treatises, and signifies the ratio in which the greater term is twice and a half times the less; as the ratio of 10 to 4, or of 15 to 6.

Sesqui. In Music, a whole and a half; which, joined with *altera*, *terza*, *quarta*, &c., is much used in the Italian music to express a set of ratios, particularly the several species of triple time.

Sessiles (Lat. sessilis, from sedeo, *I sit*). The name of a division of the class *Cirripeds*, comprehending those species which are not suspended by a pedicle.

Session, Court of. The supreme civil court of Scotland, having jurisdiction in all civil questions, of whatever nature. It was constituted by an Act of the Scottish parliament in 1537. It was intended to supply the place of the previously existing courts, and more especially of a judicial committee of parliament called the 'lords of session;' whence the name of the court and the titles of the judges. Originally it consisted of seven laymen and eight churchmen, including the president. In 1640, however, an Act was passed providing for the exclusion of churchmen from the court; and though repealed in 1661, the principle laid down in it has ever since been acted upon. Other important improvements were introduced at different periods, particularly after the Revolution, when the right of appeal from the court to parliament was, for the first time, recognised. At the Union, power was given to all individuals who considered themselves aggrieved by judgments of the Court of Session to appeal to the House of Lords; and for a lengthened period a large portion of the judicial business of the House of Lords has consisted in hearing and deciding Scotch appeals. Originally, and down to 1808, the whole fifteen judges sat together in one court; but in that year an Act was passed dividing the court into two chambers, the lord president presiding in the first division of seven judges, and the lord justice-clerk in the second of six; the two remaining judges trying cases in the first instance, or, as it is technically termed, sitting as lords-ordinary. Since that time the number of judges has been reduced to thirteen; four belonging to each of the divisions, and five acting as lords-ordinary. The judges were at first chosen by the Scotch parliament; but since 1554 they have been appointed by the crown. They are either, as already stated, called lords of session, or senators of the college of justice; which last embraces the whole body of barristers (advocates) and attorneys or solicitors who practise before the court. They must be twenty-five years of age; and, by the Treaty of Union, no person can be named to the office unless he have served as an advocate or principal clerk of session for five years, or as a writer to the signet for ten. The salaries of the ordinary judges are 3,000*l.* a year each; those of the lord justice-clerk and lord president being respectively 4,500*l.* and 4,800*l.*

At its outset, the Court of Session was intended to serve as a standing or perpetual jury for the trial of cases; the introduction of petty juries into the trial of civil cases in Scotland being only of very recent date, as well as of limited application. It was, in fact, unknown till 1815, when a special or jury court was instituted, for the trial of cases involving questions as to the value of property, or damages, or the determination of some fact. But in 1830 this court was suppressed, and the Court of Session now avails itself of the assistance of petty juries in the trial of the above description of cases. [Justiciary, Court of.]

Session of Parliament. The period between its meeting and prorogation. All the Acts passed in a session are legally considered as forming a single statute; each separate Act being designated as a chapter, and its subdivisions as sections. [Parliament.]

Sessions, Great, of Wales. A local court of the principality of Wales erected by stat. 34 & 35 Hen. VIII. c. 26, with a local jurisdiction similar to the general jurisdiction in England of the Court of Common Pleas. But by stat. 2 Geo. IV. and 1 Wm. IV. c. 70 the Court of Great Sessions was abolished, and the jurisdiction of the courts of Westminster was extended to Wales.

Sessions of the Peace. In English Law, the term *session of the peace* is applied to designate a sitting of justices of the peace for the execution of those duties which are confided to them by their commission, and by charter or statute. Such are: 1. A petty (or petit) session, which is a private meeting of two or more justices of the peace for the execution of some power vested in them by law; many Acts of Parliament requiring the concurrence of a plurality of justices, and there

being other occasions on which, although not strictly necessary, it is considered usual and expedient. One of the most important instances of the first kind is the holding parties to bail against whom a charge of felony has been entertained. 2. A special session, which is principally distinguished from the former by being public, instead of on the private motion of the justices, it being necessary that notice should be given to every magistrate of the division. Special sessions are held to grant licenses, execute the provisions of the Highway Act, appoint overseers of the poor, and for many other purposes. 3. Quarter sessions. [JUSTICE OF THE PEACE; QUARTER SESSIONS.]

Sestertium (contracted from mille sestertiorum). The sum of 1,000 sestertii; usually estimated at about 8*l.* English.

Sestertius (Lat. an abbreviation of semistertius, *two and a half*). A sesterce; a Roman silver coin, equal in value to two *asses* and a half, or nearly twopence of English money.

Set Fair. In Architecture, the coat of plaster used after roughing in and floated, or pricked up and floated. It should be well trowelled, to answer well for colour.

Set Off. In Architecture, the horizontal projection left in carrying up a wall, where the thickness of it diminishes at its different stages or stories.

SET OFF. In Law, a species of defence to a civil action, by which a party acknowledges the justice of the plaintiff's demand, but sets up a demand of his own against the plaintiff sufficient to counterbalance either the whole or a part of it.

Seta (Lat. *a bristle*). In Botany, the term applied to a bristle of any sort; a stiff hair; a slender straight prickle; also the stalk which bears the spore-case of mosses and allied plants.

Setaceous (Lat. seta). In Entomology, the antennæ which resemble a bristle are so called.

Sethians. In Ecclesiastical History, a sect of Egyptian Christians, who sprang up in Egypt in the second century. Their chief peculiarity consisted in their belief in the identity of Jesus Christ with Seth, the son of Adam, whence they derived their name. They continued to exist about 200 years.

Seticers (a word coined from Lat. seta, *a bristle*; and Gr. κέρας, *a horn*). A term applied by Latreille to a family of Lophyropodous Crustaceans, including those in which the superior antennæ are long and setaceous.

Setigers (Lat. setiger, *bristly*). The name of a tribe of Annelidans, including those which, like the earthworm, are provided with bristles for progressive motion. The *Setigera* are the first tribe of the Abranchiated order of Annelidans.

Setiremes (Lat. seta, *a bristle*; remus, *an oar*). A name given by Kirby to the natatory legs of certain aquatic insects, which are fringed with bristles.

Seton (from Lat. seta, *a bristle*; because bristles or horse hairs were formerly used to keep open the wound). A seton is an artificial ulcer, made by passing a skein of thread under a portion of the skin by means of an instrument called a seton needle: the thread is occasionally anointed with irritating substances, in order to keep up a discharge from the sore.

Setose (Lat. setosus, *bristly*). In Botany and Zoology, when a surface is beset with stiff scattered hairs.

Settee. A two-masted lateen-rigged vessel formerly used in the Levant, but now extinct, or nearly so.

Setter. A variety of spaniel, which has been taught to couch down (technically termed *set*) on the sight of game, this habit distinguishing it from the *pointer*, which dog on seeing the birds becomes stationary in the position in which he may be at the moment. The *setter* is closely allied to the water-spaniel or barbet.

Setting. In Architecture, the term *setting* is applied in the sense of the hardening of cements, limes, or plasters. It also means the fixing of the stones in walls or vaults.

Setting Coat. In Architecture, the best sort of plastering on ceilings or walls; in inferior work it is made of *fine stuff*, and when the work is very dry a little sand is used. A setting coat may be either a second coat on laying or rendering, or a third upon floating. The term *finishing* denotes the third coat, where stucco is used; that of *setting*, where the work is for paper.

Settlement. In Law, the right which an individual acquires to parochial assistance, under the statutes for the relief of the poor, in that parish or district to which he legally belongs, and in which he is said to have the settlement. [POOR LAWS.]

Settlement, Act of. The statute 12 & 13 Wm. III. c. 2, which vested the succession to the crown, after the death without issue of King William III. and Queen Anne, upon the Princess Sophia (being the youngest daughter of Elizabeth, queen of Bohemia, who was the daughter of James I.) and the heirs of her body being Protestants.

Settlement of Property. By the English Law, the unsettled fortune of a wife is placed very much in the power of her husband, and the rules regulating the transmission of property among married persons and their issue are in other respects found to be practically unsuited to the requirements of families. It has therefore become usual, whenever circumstances will admit, to make arrangements previously to a marriage, to secure some certain provision for the wife and children, and to protect the family property against the effects of extravagance, misfortune, or caprice. The instruments by which these arrangements are carried out are known as *marriage settlements*, and vary to some extent in each particular case, though the same general form is usually followed. Stock or other personal property is usually vested in

trustees and settled upon the husband and wife successively for life (the wife if she takes the first life interest being protected against the control or engagements of the husband), and after their deaths upon trust for all or any of the children as the husband and wife or the survivor of them may appoint, and in default of appointment upon trust for the children equally (sons at twenty-one, daughters at twenty-one or marriage). Real estate of small value is usually directed to be sold and the proceeds settled as personalty, for property of this nature cannot be advantageously enjoyed in specie in undivided shares. Real estates of considerable value are usually settled upon the husband for life, often with an annual allowance for the wife by way of *pin money*. Provision is then usually made for payment of a jointure to the wife, if she survive her husband, and for raising portions for the younger children, subject to which the estates are entailed upon the sons of the marriage and their issue successively, with remainder to the daughters and their issue.

Settlements of property are often made on other occasions than that of marriage, and are then known as *family settlements*. Settlements of estates by way of entail are known as *strict settlements*, and often contain limitations carrying the estates to the collateral branches successively of a family, clauses compelling the assumption of a particular name, or of arms, and other complicated provisions. As, however, the first tenant in tail, who is usually the eldest son of the first tenant for life, can on attaining twenty-one (with the consent of the tenant for life if living) bar his estate tail and all subsequent estates or interests, it rarely happens that all the limitations of a settlement are allowed to fall successively into possession; and, as a matter of fact, the great estates in this country are usually re-settled in every generation, and often as soon as the eldest son of the landowner in possession attains majority. In settlements of all kinds it is necessary to insert numerous powers and clauses with respect to investments, leases, sales, and other particulars relating to the management of the settled property, much prolixity being thus occasioned. There is little doubt that the continued repetition of these provisions might be dispensed with by a suitable amendment of the law, but an attempt which has been recently made in this direction has not proved very successful (stat. 22 & 23 Vict. c. 35).

Seven Years' War. In History, a war carried on in Germany between two alliances, headed respectively by Austria and Prussia, from the year 1756 to 1763, when it was ended by the peace of Hubertsburg. It was signalised chiefly by the extraordinary campaigns of Frederick II. king of Prussia. His principal ally throughout the struggle was England; while he was, at one period, assailed by the forces of Austria, France, the Empire, Sweden, and Russia. When the forces of the Prussian sovereign had been almost annihilated by this coalition, the death of the Russian empress, Elizabeth, caused the withdrawal of Russia from the alliance of his enemies, and thus brought about the termination of the war.

Seventh. In Music, an interval, of which there are three species. First, the diminished seventh, consisting of nine semitones, as from C♯ to B♭. Second, the minor seventh, consisting of ten semitones, as from C♮ to B♭. Third, the major seventh, being only a major semitone less than the octave, as from C to B♮.

Severite. A variety of Halloysite, somewhat resembling Lithomarge. It is a hydrated silicate of alumina, found in small masses, from two to five inches in diameter, in Tertiary deposits at St. Sever in France.

Sewage. The drainage water of towns, including all sorts of house waste. Since the adoption and extended use of water-closets, the waste water of towns has become more offensive than, in the old days of privies and cesspools, it used to be; and enactments are now being levelled against the increasing consequent pollution of rivers. The agricultural utilisation of this filthy drainage water is the true remedy for all the evils complained of. The soil deodorises the water poured over it, which flows off purified, leaving behind it as the food of plants those ingredients whose putrefaction would have poisoned the air. Its leading fertilising ingredient is nitrogen in some of the many forms which by decomposition yield ammonia. Sewage generally yields ammonia at the rate of about seven grains in a gallon, or 1 in 10,000 of weight. This extreme dilution forbids all hope of extracting the valuable part of town drainage water except by employing a growing plant for the purpose; and the use of the liquid, as of water in irrigated meadows, by letting it flow over the surface of grass land, seems to be the best or indeed the only method of turning it to useful and profitable account. In this way 100 to 150 tons of sewage may produce a ton of grass; and as that near towns is worth 18*s.* to 1*l.* per ton, we get 2*d.* per ton as, under ordinary circumstances, the total value of the sewage water of towns. For the expense of hiring land and labour in the process we must, however, deduct one-half to three-quarters of the whole receipts, so that if ultimately towns shall obtain ¼*d.* to ½*d.* a ton for their drainage stuff as a contribution towards their expenditure and sewers, the result must be considered satisfactory. In the first instance, the risk of the venture being considerable, the only arrangement possible with any company who should propose to take the sewage for agricultural use is that either of simple gift for a term of years, or of reserving an ultimate share in the profits after they have been realised.

It is proper to add, that no one has yet succeeded in extracting 2*d.* per ton from sewage; but there seems reason to expect that better and more economical field arrangements may

yet succeed in realising the anticipations of the theorist. Taking guano at 7*l*. 14*s*. per ton, and 828 tons of sewage equal in fertilising power to a ton of guano, Liebig reckons that the sewage of London is worth 1·84*d*. per ton, or has an annual value of 15*s*. 4*d*. per head of the population, 100 tons of sewage per annum being considered as about the amount of sewage due to each individual. Dr. Hoffmann's estimate does not differ much from this. He considers the sewage to be worth about 2*d*. per ton, or to be worth 17*s*. 7*d*. per head of the population; and taking the population at 2,600,000, the bulk of sewage annually discharged by the sewers would be 266,000,000 tons, and its annual value 1,385,540*l*. Estimates of value not widely differing from these have been given by Voelcker, Sir C. Fox, Hope, Lawes, Ellis, Mechi, and others. Many expedients for deodorising sewage have been propounded, but none of them generally adopted, and the conviction seems now to be that the soil itself is the best deodoriser. Nor is there yet much agreement as to the best modes of applying sewage to land. On the whole, the best plan seems to be to apply it in the same way in which water is applied to irrigate the fields. The sewage may be run over the fields, which should be divided into beds some 50 yards wide, with a slope of 1 in 120, or thereabout; so that, carried along the ridge line of the beds, it may trickle down their sides to the furrow which will act as a surface drain, and carry it to where it may be again used on a lower level.

Sewer. In Architecture, a subterraneous conduit, or channel, to receive and carry off the superfluous water and filth of a city. The sewers of Rome have been the models of those of the modern cities of Europe. The cloacæ had, between the Quirinal, Capitoline, and Palatine hills, many branches, which joining in the Forum, now the Campo Vaccino, were received for conveyance into the Tiber by a larger one, called the *cloaca maxima*. It must be admitted, however, that it is erroneous to designate the Roman cloacæ by the term sewers. They were rather drains, made to carry off the stagnant water of the pestilential marshes which occupied much of the low ground near the Tiber, and the spaces between the Aventine, Palatine, and Capitoline hills. The height and width of the cloaca maxima are equal, each measuring 13½ feet.

Arched drains or sewers have been found in the ruins of Assyrian cities. In modern sewers, which are built of brick set in cement, the section is generally made of an egg form, with the smallest end downward, with a view of obtaining the necessary strength against compression, and of narrowing the surface of the stream of sewage, as it becomes shallower, so as better to maintain the scouring action due to its velocity, and thus to diminish deposits which would virtually convert the sewer into a long cesspool. The effect of improving the sewerage of towns has been to pollute the rivers into which the sewers discharge to such an extent, that it has been necessary in London and in some other large towns to construct intercepting and transmitting sewers of large size, which transmit the sewage to a point of the river sufficiently near the sea to get rid of it without offence. The intercepting sewers, like catch-water drains, receive as much of the sewage as can be collected at the level which is necessary to transmit it by gravity to its destined outlet; and the portion which cannot be thus transmitted is collected by a sewer at a lower level, and after having been conducted sufficiently far along the banks of the river to be clear of the town is pumped by steam engines or otherwise up to the higher level, where it can be disposed of in common with that transmitted by the intercepting sewer. But many are now of opinion that the whole system of the sewerage of towns is constructed upon an erroneous principle, since the sewers are, in fact, made to fulfil two separate functions, the proper discharge of which is impossible in a single system. The original function of the sewers of most existing towns was to carry off the rain which fell on the streets and houses into the nearest river. But the changes introduced into the domestic arrangements of our houses during the present century, have superadded the function of transmitting such refuse to that of transmitting the mere surface water. Now, as rain falls at irregular times, and sometimes in very large quantities, the sewers require to be large to be able to transmit this large volume of water; and in dry weather, but for the sewage proceeding from the houses, the sewers would be empty and dry. The small stream of sewage, however, requiring at such times to be transmitted does not flow at a sufficient velocity to carry on all the matters suspended in it, and the sewers thus virtually become long and high cesspools with a thick deposit of fetid mud at the bottom. In heavy rains no doubt a large part of this deposit is swept out; but this action leads to the further evil that the volume of sewage becomes at these times so great that it is difficult to deal with it, since the transmitting and distributing capabilities of any conduits employed to lead it away must be made equal to the greatest pressure which is likely to be put upon them on the worst occasions. These evils point to the propriety of having two systems of sewers in towns, of which one (best formed with clay or iron pipes) shall be devoted to the single purpose of transmitting the sewage of the houses to some appropriate terminus; and as this sewage is not large in volume, and is nearly uniform in quantity, the dimensions of such sewers need not be great. The ordinary sewers would thus be restored to their primary function of transmitting the surface waters alone, and these waters might be conducted into the nearest river without sensibly polluting it. This system was tested and advocated by Mr. Simpson, of Edinburgh, about 1340; but al-

though it has often been since advocated by others, it has not yet been adopted. The quantity of sewage yielded by a town would be approximately measurable under this system by the quantity of water delivered to it, according to which the sizes both of the water pipes and sewer pipes should be computed, whereas the dimensions of the sewers for transmitting the surface water would be properly measurable by a reference to the maximum rainfall in a given time, and the area of ground from which the water had to be conducted. For further information, see SEWAGE; and also reports made to the Metropolitan Board of Works; Hellerstedt's Paper on the Paris Sewers; Reports by Messrs. Hawksley, Wickstead, Bateman, &c., on the sewerage of various towns in England, and Reports published by the General Board of Health.

Sewers, Commissioners of. These commissioners have been appointed by the crown from very early periods to enforce the law relating to the defences of the land against the sea, and inundation by land floods and to the free course of navigable rivers. The law on the subject was extended and settled by the statute of Sewers (23 Hen. VIII. c. 5), and many subsequent Acts have since been passed. The commissioners are a court of record, and may fine and imprison for contempts, and have various powers of levying rates. The Land Drainage Act of 1861 contains some important provisions on the subject.

Sewing Machine. Sewing machines have been divided into four classes. In the first, the needle is passed completely through the stuff, as in hand-working; but this method, adopted naturally in the infancy of the invention, has been generally abandoned. The sewing machines of the second class are known as the chain-stitch or *crochet* machines, wrought by a so-called crochet needle, which terminates with a hook. In the third class, the machines are wrought by two threads, the stitch produced by them being known in America as the mail-bag stitch. The fourth class of sewing machines produce more complex stitches, which are formed by sewing two threads, mutually interlacing each other in chain stitch, so as to avoid the unravelling to which the simple chain stitch is subject. For a description of these several classes of machines, the reader is referred to the art. 'Sewing Machines' in Ure's *Dictionary of Arts, Manufactures, and Mines.*

Sexagesima (Lat. *sixtieth*). In the Calendar, the eighth Sunday (nearly sixty days) before Easter.

Sexagesimal Arithmetic. A method of computation proceeding by sixties (as the common arithmetic proceeds by tens), and used by the ancient Greek astronomers for facilitating arithmetical calculations, particularly division and the extraction of roots; operations which, when performed on numbers expressed by the complicated Greek notation, are attended with great labour and difficulty.

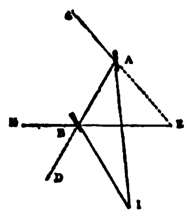
Sexagesimal Fractions. In Arithmetic, such fractions as have 60, or some multiple of 60, for their denominator. Fractions of this kind were anciently the only fractions used in astronomy; and they are still retained in the division of the circle, and of time, where the degree, or hour, is divided into sixty minutes, the minute into sixty seconds, and so on.

Sextans or **Sextant.** In Astronomy, one of the constellations formed by Hevelius. It is placed across the equator, and on the south side of the ecliptic.

Sextant (Lat. sextans, *the sixth part*; the limb of the instrument being the sixth part of a complete circle). An instrument for measuring the angular distances of objects by reflexion. The sextant is capable of very general application; but it is chiefly used as a nautical instrument for measuring the altitudes of celestial objects, and their apparent angular distances. It is an instrument of the utmost importance in navigation.

The principle of the sextant, and of reflecting instruments generally, depends upon an elementary theorem of catoptrics; viz. if an object be seen by reflexion from two mirrors which are perpendicular to the same plane, the angular distance of the object from its image is double the inclination of the mirrors. Thus, let A and B be sections of two mirrors perpendicular to the same plane, and inclined to each other in the angle A I B; a ray of light coming from the sun and falling upon the mirror A, in the direction S A, will be reflected in the line A B; and falling upon B, it will again be reflected in the direction B E. Let A B be produced to D, and S A prolonged to meet B E in E. Now, since the angles of incidence and reflexion are always equal [REFLEXION], we have D B E = 2 D B I, and B A E = 2 B A I; but D B E = B A E + B E A, and D B I = B A I + B I A, consequently B A E + B E A = 2 B A I + 2 B I A; and therefore, since B A E = 2 B A I, we have also B E A = 2 B I A; that is to say, the angular distance between the object S and its image seen by the eye at E, in the direction E B H, is the double of the inclination of the mirrors. It may be remarked, that the place of the image, as seen from E, is independent of the situation of the mirrors on the plane, so long as the line of the intersection of their planes and their inclination to each other remain constant.

Fig. 1.

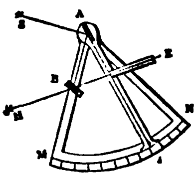


From what has been now said, it may be seen that if a convenient method could be devised for measuring the inclination of two mirrors perpendicular to the same plane, when they are so placed that the image of an object S is brought to coincide with an object H seen directly, we should at once have a reflecting instrument for measuring angular distances.

Such instruments are the *sextant*, the *quadrant*, the *reflecting circle*, respectively so called from the extent of the arc which the graduated limb embraces.

The contrivance adopted for this purpose in the sextant is to attach the frame of the mirror B to the plane of the sector of a circle A M N, and the frame of the mirror A to a radial bar A I revolving in the plane of a sector round a pin passing through the centre. Both frames are generally supplied with the means of adjusting the planes of the mirror vertically, and B is generally also capable of being turned by a delicate motion a small way round a pin passing through the frame of the sector.

Fig. 2.



The arc or *limb* M N of the sector is graduated; and the revolving radius or *index* carries at its extremity a vernier scale, applying to the graduations on the limb, and subdividing them into such smaller portions as may be desired.

The method of finding the zero point of the limb may be understood generally from the following considerations: The angle E (fig. 1) being double the angle I, it follows that when the mirrors are parallel, or the angle I is nothing, the angle E is nothing also, and S and its image will appear as one object, the one exactly covering the other. It is therefore only necessary to turn round the radial bar which carries A till the image of a distant object seen by reflexion from B is in accurate conjunction with the object itself, seen directly; and the point on the limb at which the index then stands is the zero point of the arc. If it is not also the zero of the numbered graduations, its distance from the numeral zero is called the *index* error of the instrument, and is to be applied as a correction to all angles measured.

In graduating the limb, half degrees are marked as whole ones, and the smaller divisions accordingly; so that the angle read from the instrument is not the inclination of the mirrors, but the distance of the object from its image. In this class of instruments, therefore, 90° are indicated by an arc of 45°, 120° by an arc of 60°, &c.

The mirror A is completely silvered behind; but B is silvered on that half only which is next the plane of the instrument, the upper part being left clear, that objects, such as H, may be seen *through* the upper portion of it, as well as the images of others, as S, by reflexion *from its lower, silvered, surface*. The mirror B is so placed by the maker that when A is parallel to it, the index, which carries A, either exactly or nearly corresponds with the zero of the divisions as they are numbered on the limb. When the index has been set by hand nearly in the position requisite for measuring any proposed angle, it is clamped to the limb by a screw acting on a spring, and moved slowly by a tangent screw till it attains accurately the required position.

Such being the general principles of the instrument, we shall now briefly describe the different parts of it, as constructed by the best makers, and the methods of adjusting and observing with it.

The only important object to be aimed at in the frame is to combine lightness with sufficient strength.

The telescopes used are of two kinds. One, a direct telescope, which is simply an opera-glass; and having a narrow field of view, is generally used in the more ordinary sort of observations, such as observing altitudes. The other is an inverting or astronomical telescope. In the frames of each eye-piece are two pairs of wires, each pair perpendicular to the other, dividing the field of view into nine spaces, of which that in the middle is square; and it is important that in all observations made with this instrument the contact of the image seen by reflexion, and of the object seen directly, should be made as near the middle of this square as possible, at any rate at the same distance as the centre of the square from the plane of the instrument.

It is essential, also, that the telescope should be parallel to the plane of the instrument; and in the collar into which the telescope is screwed there are two screws for making this parallel adjustment. The adjustment is not very liable to alter, but no careful observer will omit to examine it at every convenient opportunity.

Both the mirrors are supplied with coloured glasses of different degrees of shade, framed and placed in such a position that they can be turned down before the mirrors, either singly or combined. The eye-pieces of the telescopes are also supplied with coloured shades, set in caps, which are screwed on the eye-piece. They are used in taking the index error by means of the sun, and in observing the sun's altitude from an artificial horizon.

Adjustment of the Sextant.—1. To set the index glass, when it admits of adjustment, perpendicular to the plane of the instrument.

Place the index about the middle of the limb; and looking obliquely into the index glass, the part of the limb will be seen by reflexion in the glass, as well as directly. If the part of the limb seen directly and its image in the glass appear as one continued frame, the mirror is in adjustment; but if the reflected image appears to incline downward, it shows that the face of the glass inclines backward from the perpendicular; if upwards, that it inclines forward, and the adjustment must be made by the screw supplied for the purpose.

2. To set the horizon glass perpendicular to the frame of the instrument.

Having carefully adjusted the index glass, or seen that it is in adjustment, screw the telescope into its socket; adjust the eye-piece to distinct vision; screw the dusk shade cap on the eye end of the telescope, or turn down

shades before the mirrors; and looking towards the sun, bring the index near to zero; move it steadily backwards and forwards, and the reflected image of the sun will be seen to pass over his disc, as viewed directly. If the two circular discs accurately cover each other in passing, the perpendicular adjustment of the horizon glass requires no adjustment; but if they pass a little aside of each other, so that two different-coloured lines appear on each side of the overlapping middle part, the mirror B must be turned by the appropriate screw till the discs accurately cover each other, when the adjustment will be complete. This adjustment may also be effected by making a bright star and its image coincide with each other; but in this case it is scarcely necessary to say that the darkening shades must be turned aside.

3. To set the telescope parallel to the plane of the instrument. This adjustment is effected by two screws in the collar which attaches the telescope to the limb of the sextant, diametrically opposing each other in a line perpendicular to the plane of the instrument. By tightening the upper one the object end of the telescope is inclined towards the instrument, and the contrary effect is produced by tightening the lower one. To make the adjustment, turn round the eye-piece of the telescope till two of the wires in its focus appear parallel to the plane of the instrument (and of this the eye can judge with sufficient accuracy); then take two objects, as two bright stars, or the sun and the moon, whose distance in either case should not be less than 90°, in order that any error in the adjustment may become more apparent, and bringing the image of one of the objects in accurate contact with the other object on the wire next the instrument, *instantly* bring them to the other wire; and if they are also in accurate contact upon that wire, it may be concluded that the axis of the telescope is parallel to the plane of the instrument. If the objects are the sun and moon, and they separate at the farther wire, it shows that the object end of the telescope inclines towards the plane of the instrument, and the contrary if they overlap; and the error must be corrected by turning the proper screws in the collar.

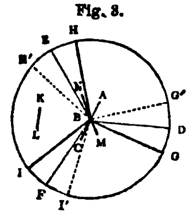
The index error of the instrument may be most conveniently and accurately determined, as follows. Having effected the perpendicular adjustment of the horizon glass by the method above explained, bring the border of the sun's reflected image to coincide with the sun seen directly both on the right and left side; and, reading the index at both observations, if one reading is on the left and the other on the right of zero, *half the difference is the index error*, and the fourth part of the sum is the sun's semidiameter; but if both readings are on the same side of zero, *half the sum is the index error*, and the fourth part of the difference is the semidiameter.

The Reflecting Circle depends on the same principles as the sextant, from which it differs chiefly by having the whole circle graduated. In some instruments of this kind the angle is measured by repetition. [REPEATING CIRCLE.]

But the only instrument of this kind that can be now said to be in general use in this country is Troughton's reflecting circle; in which, by means of three equidistant indexes, and by observing alternately with the face of the index direct and reversed, *six times* the required angle is obtained, without reference to the index correction. After what has been said above on the principles of reflecting instruments generally, the following short account of this instrument will be sufficient.

All the indexes move round together; and, of course, the apparatus for slow motion, or the tangent screw, is requisite only for one of them, which is called the *leading* index, and which, for the sake of convenience, stands at or near zero on the limb when the revolving and fixed mirrors are parallel.

Fig. 3.



In the annexed figure let B D, B E, and B F be the positions of the indexes when the revolving mirror is parallel to the fixed one K L; and let A C and M N be two positions of the revolving mirror when it is equally inclined to K L. Then the arcs D G, D G′, E H, E H′, F I, F I′, passed over by B D, B E and B F, will be all equal; and if, when the mirror has the position M N, the face of the instrument be reversed, M N and K L will have the same relative position to each other that A C and K L have; and consequently if an object is seen by reflexion from A C and K L, it will also, when the instrument is reversed, be seen by the reflexion from M N and K L to an eye placed in the same situation. Hence the degrees on the arcs G G′, H H′, I I′, which are the differences of the readings of the observations in the direct and reversed positions, are each the measure of double the distance of the object from its reflected image. The degrees being numbered round the circle from 0 to 720°, and the indexes placed very nearly at equal distances from each other, it is customary in practice to read the degrees, with the minutes and seconds, from the leading index only, and to read only the minutes and seconds at the other indexes.

Sextile Aspect. In Astrology, the aspect of two planets when they are distant from each other the sixth part of a circle, or sixty degrees.

Sextinvariant. [INVARIANT.]

Sexton (a corruption of *sacristan*). A church officer, who is properly the keeper of holy things belonging to divine worship, and said to be the same with the *ostiarius* in the Roman church. A sexton is usually appointed for life (whether by the minister or others, according to custom), and in such case a mandamus lies to restore him to his office.

Seybertite. A kind of Clintonite, found

in beds of granular limestone, at Amity in New York.

Sforzato or **Sforzando** (Ital. *forced*). In Music, a term written over a note to signify that it is to be played or struck louder than the rest; it is abbreviated *sf* or *sfz*.

Sfumato (Ital. *smoky*). In Painting, a term applied to that style of painting wherein the tints are so blended that the outline is scarcely perceptible, the whole presenting an indistinct misty appearance. The Milanese painters exhibit this quality more than any others.

Sgraffito or **Sgraffiato** (Ital. *scratched*). In Painting, a species of drawing in which the ground is prepared with dark stucco, on which a white coat is applied; which last being removed with an iron instrument, the scraping it away forms the shadows, giving it the appearance of a chiaroscuro painting. The principal designs of Polidoro da Caravaggio are executed in this manner, which is capable of great effect, and is extremely durable.

Shabrack. The large saddle-cloth, forming part of the full-dress equipment of officers of cavalry and horse artillery. The term is said to be of Hungarian origin.

Shackle. On Shipboard, a ring. The term is applied more especially to the rings of the ports through which the port-bar is passed to close the porthole effectually, and to the ring of the anchor by which it is attached to the cable.

Shad (Ger. schade). A large species of herring, the *Clupea alosa* of Linnæus. It forms a separate genus in the Cuvierian system.

Shaddock. The fruit of the *Citrus decumana*, one of the species of the Orange family. It is said to be named after the person who first carried it from the East to the West Indies.

Shadow (A.-Sax. sceadn, Ger. schatten, Gr. σκότος and σκιά). In Optics, a portion of space from which light is intercepted by an opaque body. As the rays of light proceed in straight lines, every opaque object on which light falls is accompanied with a shadow on the side opposite to the luminous body; and the shadow appears mere intense in proportion as the illumination is stronger, because any object placed within it contrasts more strongly with the surrounding objects on which the light is suffered to fall.

As every point of a luminous body is a separate focus of illumination, it follows that an opaque object illuminated by the sun, or any other source of light which is not a single point, must have an infinite number of shadows, though not distinguishable from each other; and hence the shadow of an opaque body received on a plane is always terminated by a *penumbra*, or partial shadow, the extent of which is greater in proportion to the magnitude of the luminous body, the distance of the opaque body from the plane on which the shadow falls, and the degree of obliquity with which the luminous rays fall on the plane.

Coloured Shadows.—In certain states of the atmosphere the shadows of opaque objects projected on a white surface are frequently observed, about the time of sunrise or sunset, to be of a blue colour. This curious observation appears to have been first made by the celebrated painter Leonardo da Vinci, and is also noticed by Otto Guericke in his *Magdeburg Experiments*; but no further notice seems to have been taken of the phenomenon until about a century later, when it was again noticed by Buffon. Happening to stand on an eminence about the time of sunset, he perceived the shadows of the trees on a white wall about 30 or 40 feet distant to be coloured with a light green, inclining to blue. The next morning, at sunrise, he repeated the observation; but instead of finding the shadows green, he found them blue, or rather the colour of lively indigo. Afterwards he often observed the shadows both in the morning and evening, but always observed them to be blue; and he remarks that any one may see a blue shadow, if he will hold his finger before a piece of white paper at sunrise or sunset. The phenomenon has since been frequently observed, and is now known to be due to the hyper-sensitiveness of that portion of the retina of the eye which receives the image of the shadow, for rays complementary to those which are illuminating the rest of the retina; thus in the *red* glow of evening, a surface in shadow, which is in fact reflecting a subdued light, appears *green*, whilst with a *yellow* light from the rising or setting sun shadows appear *blue*. [COMPLEMENTARY COLOURS.]

SHADOW. In Painting, the form which a solid object projects on a surface or surfaces by being interposed between the surface or surfaces and the sun, or other luminous body. [SCIOGRAPHY.] *Shade* is a term applied to that portion of the object which is not obvious to the luminous body.

Shaft (A.-Sax. sceaft). In Architecture, that part of a column between the base and capital, sometimes called the *trunk* of the column. The shaft of a column always diminishes in diameter from about a third of its height. Sometimes it has a slight swelling [ENTASIS] in the lower part of its height. In the oldest Doric columns, the diminution was so considerable as to give the column a conical appearance. In the Doric edifices at Athens, the upper diameter is not more than a quarter less than the lower diameter; in the temples of Jupiter Nemeus, between Argos and Corinth, not more than a fifth less. In Ionic and Corinthian columns, the difference of the upper and lower diameters varies from a fifth to a twelfth. The ancients seem to have regulated the diminution in some proportion to the absolute height of the column, for no particular law seems to have prevailed in terms of the lower diameter.

SHAFT. In Mechanics, that part of a machine in which the motion is communicated by torsion, as in the paddle-shaft or screw-shaft of a steamship.

SHAFT. In Military Mining, the vertical

excavation made to reach the required position for the charge. Horizontal or inclined excavations are called *galleries*.

Shag (A.-Sax. sceacga). The English name of a species of cormorant (*Pelicanus graculus*, Linn.).

SHAG. A term used in Scotland for the refuse of barley. Also the commercial name for a kind of prepared tobacco.

Shagreen. A species of leather, supposed formerly to have been prepared from the skin of the *shagree*, a species of whale. It is prepared from horse or ass skin, its granular appearance being produced by embedding in it, whilst soft, the seeds of a species of chenopodium, and afterwards shaving down the surface: it is dyed with the green produced by the action of sal ammoniac on copper filings. It was formerly much used for watch, spectacle, and instrument cases, and was made chiefly in Astracan.

Shah (Pers. *prince*). The title given by European writers to the monarch of Persia, who in his own country is designated by the compound appellation of PADISHAH.

Shah-namah (*The Book of Kings*). The most ancient and celebrated poem in the modern Persian language, by the poet who received as a title of honour the name 'Firdousi' (*of Paradise*), by which he is known. Its date is supposed to be about A.D. 1000. A complete translation into English, in four volumes, was published by Captain Macan, Calcutta 1829.

Shake (A.-Sax. sceacan). In Music, a quick alternate repetition of the note above with that over which the mark *tr* is placed, commonly ending with a turn from the note below.

Shakers. In Ecclesiastical History, a sect said to have originated by a secession from the body of Quakers, in 1747, in Lancashire; they received their nickname from the peculiar contortions of body which they adopted in their religious exercises. Anne Lee, the leader of this sect, joined the society in 1758; and considering herself persecuted in England, went with a few followers to New York in 1774. She died ten years afterwards, at which time her sect had made great progress in America.

Shako. The headdress worn by all infantry of the line in the British army, and by the Austrian and some other troops.

Shale (Ger. schale, *a shell*). A name given to certain argillaceous rocks, which split in some degree like slate, but much less perfectly, and are so little altered as to be easily reducible to clay by mechanical rubbing and pounding. Shales are very common in the coal measures, both in England and elsewhere, but they are not essential to the presence of coal. Some shales contain a marked proportion of bituminous matter capable of being separated by distillation at a low and regulated temperature. These are called bituminous shales, and, though generally distinct, they pass into coals in some places and cannot be distinguished from them. [BITUMINOUS SHALES.] Shales differ from schists in being almost entirely argillaceous and slightly metamorphic. Their impurities are iron and limestone, which occur as accidental and not as essential ingredients. They differ from slates in being less perfectly metamorphosed.

The shales in the coal measures are often loaded with fossil plants, which are very slightly changed. Slates, when they contain fossils, exhibit them in a greatly altered state, and schists contain only inorganic and crystalline minerals. Notwithstanding these broad distinctions, the young geologist may occasionally find difficulty in distinguishing shales from slates, and either of these rocks from schists. [SCHIST.]

Shallop (Fr. chaloupe). An open, broad boat, once employed by fishermen, but now nearly superseded by luggers and yawls. It has two masts rigged schooner-fashion.

Shallot or **Eschalot** (Fr. échalotte). The *Allium ascalonicum* of Linnæus. It possesses the flavour of garlic, but is less pungent, and is highly esteemed in cookery.

Shamanism or **Schamanism.** A general name applied to the idolatrous religions of a number of barbarous tribes, comprehending those of Finnish race—the Ostiaks, Samojeds, and other inhabitants of Siberia as far as the Pacific Ocean. These nations generally believe in a Supreme Being, but they assign the immediate government of the world to a number of secondary gods, both benevolent and malevolent towards man. The *shamans* or priests possess the power of propitiating such as are malignant. For accounts of these remote people, see Von Wrangel's *Journey to the Polar Sea*.

Shammy or **Shamoy.** The tanned or tawed skin of the chamois goat. Any soft pliable leather now passes under the name. [LEATHER.]

Shampooing. A name given to an operation which consists in pressing the joints and rubbing them, so as to mitigate pain, and restore tone and vigour to the parts.

Shamrock. The popular emblem of Ireland, corresponding to the rose of England, and the thistle of Scotland. It is generally believed to have been the plant called white clover, *Trifolium repens*; but others suppose it to have been the wood sorrel, *Oxalis Acetosella*.

Shank. In Architecture. [FEMUR.]

Shank of an Anchor. The shaft or principal member. It sustains the flukes at one end and the shackle at the other; it passes through the beam, if of wood, or is pierced by it if of iron.

Shank of a Hook. The straight part above the bent portion.

Shank Painter. The rope or chain which passing round the shank of the anchor, lying horizontally, confines it to the ship's bow, abaft the cathead.

Shark (Lat. carcharus, Gr. κάρχαρος). A large genus of fishes (*Squatus*). All these fishes have five branchial openings on each side of the neck, resembling two fissures.

Some are ovo-viviparous, whilst others lay eggs covered with a hard and horny case.

Sharp (A.-Sax. scearf, Ger. scharf). In Music, a character ♯, which prefixed to a note signifies that it is to be sung or played a semitone higher than it naturally would have been without such character.

Shaster. The Hindu name Shaster, or Sastra, denotes the book which contains the interpretations or explanation of the Vedas by *sasta*, i.e. science. Of such books we have the Vedanga-Schastra, the Schastra-Bade, and several others.

Shea Butter. A kind of solid oil, obtained in Africa from the seeds of the Shea-tree, *Bassia Parkii.*

Sheaf. In Mechanics, a solid cylindrical wheel fixed in a channel and movable about an axis, as in the block of a pulley. [SHEAVE.]

Shear Steel. A kind of steel made by welding several bars together, and again drawing them out. It is used for clothiers' *shears*, and many other cutting instruments. [STEEL.]

Shearing. The term in Scotland for reaping.

Shearing Sheep. The operation of clipping off the wool from the bodies of ewes and lambs; generally performed in the beginning of summer, when the animals are not likely to suffer from being deprived of their warm covering, and when there is sufficient time for the wool to grow again before winter.

Sheath (A.-Sax. sceath, Ger. scheide). In Botany, a term applied to a petiole when it embraces the branch from which it springs, as in grasses; or to a rudimentary leaf which wraps round the stem on which it grows, as in the scape of many Endogenous plants.

Sheathing. The covering laid on a ship's bottom to defend it from the worms. Sheets of thin copper nailed on with copper nails constitute, at present, the sheathing of all the better kinds of vessels. Lead has been used, at least as early as the time of Trajan; thin planking of fir was subsequently employed; and large-headed iron nails, called *scupper nails*, are used still for the same purpose on the bottoms of old hulks, piles, &c. Zinc and different compositions have been proposed as substitutes for copper, but they have proved less successful, as the copper produces by its oxidation a poisonous acid which deters sea-animals from adhering. The oxidation, however, gradually wastes the copper; and Sir H. Davy ingeniously suggested the application of pieces of zinc or iron upon different parts of the copper surface. These pieces of zinc or iron by the action of the sea-water render the copper electro-negative, and capable, therefore, of resisting the oxidising and corrosive agencies of the substances held in solution. The pieces so applied have been properly called *protectors*; but by occasioning the precipitation of earthy matters upon the copper, while they effectually *protect it*, they render its surface favourable to the adhesion of weeds, barnacles, &c., and sometimes to such an extent as to interfere with the passage of the ship through the water: and upon these grounds Sir Humphry's valuable suggestion has been neglected. When vessels are laid up in dock, the protectors are in successful use.

Sheave. The wheel in a pulley. In ships' blocks it is usually of brass or lignum vitæ, not unfrequently in combination, a square coak or bush of brass being inserted in the centre of a wheel of lignum vitæ. *Sheave-hole* is the hole through a block or spar in which a sheave is fixed.

Shechinah (Heb. shâkan, *to dwell*). The Jewish name for the Divine presence, which is represented as resting, in the shape of a cloud, over the 'propitiatory,' or 'mercy-seat,' as it is rendered in our translation (Lev. xvi. 2). The Jews reckon it among the five particulars which were present in the first temple, and wanting in the second. On this account God is so often said in Scripture to 'dwell between the cherubim;' i. e. between the images of cherubim on the mercy-seat. (1 Sam. iv. 4; Psalm lxxx. 1, &c. See, amongst other authorities, the special dissertations of Lowman and Skinner *On the Shechinah.*)

Sheep. [OVIS.]

Sheepshank. A very useful knot for shortening a rope in the middle, without cutting it or loosening its ends. It is of service in preventing two blocks coming together, or in shortening the backstays when a mast is struck. This knot (shown at fig. 5, art. KNOTS) is formed by doubling the rope in three parts, and taking a hitch over the bight at each end with the other rope.

Sheer (A.-Sax. scyr, Ger. schier). The curve which the line of ports, or of the deck, presents to the eye when viewing the side of the ship. When these lines are straight, or the extremities do not rise, as is most usual, the ship is said to have a straight *sheer.*

Sheer Battens. In Shipbuilding, long battens by which the position of the wales or bends is marked on the timbers preparatory to those planks being bolted on.

Sheer Plan. In Naval Architecture, the longitudinal section of a ship, taken through the keel, at right angles to the horizon. It shows the position of every point in the vessel in regard to its distance fore or aft of the midship point, and to its height above the keel.

Sheer Strake. In Shipbuilding, a thick strake of planking immediately under the gunwale.

Sheers. Apparatus for raising heavy weights to a considerable height, as hoisting masts into a ship, or boilers into a steam-vessel. The easiest-formed sheers are made of two spars lashed together near the top with a block suspended from the point of intersection. The resemblance borne by such spars to an open pair of shears is said to have suggested the name. In permanent sheers, employed in dockyards, the upper ends of the spars are cut off, the tops joined by an iron cap and bolts, the bases firmly set in masonry, and the appa-

ratus is lowered or raised by chains working to the top of a massive mast, rising vertically from between the feet of the spars. In some instances a pair of sheers is placed on each side of the centre spar, the whole being built on a stone causeway, between two basins.

A sheer hulk is an old hull fitted with sheers. It has the advantage of locomotion, but the weight of modern boilers and masts is so great as to have caused the sheer hulk to become nearly obsolete. Its place has in some degree been taken by the DERRICK.

SHEERS. In Artillery, two spars from thirty to forty feet long, lashed together at one end. Their other ends are planted in the ground, the lashed ends being raised by tackle, and fixed by guy ropes. To the lashed end is attached a tackle; and the whole arrangement is used for mounting and dismounting guns from towers, &c., in the same manner as a DERRICK.

Sheet (Span. escota). The rope attached to the after or leeward clew or corner of a sail, to extend it to the wind. In the square sails above the courses, the ropes attached to both clews are called *sheets*: in all other cases the weathermost one is called a *tack*.

Sheet Anchor. The largest and most powerful anchor carried by a ship.

Sheik (Arab. *elder* or *eldest*). A title of dignity properly belonging to the chiefs of the Arabian tribes or clans. The heads of monasteries are also in some instances termed sheiks among the Mohammedans. It is also the title of the higher order of religious persons who preach in the mosques. The mufti of Constantinople bears the title of Sheikh-ul-Islam.

Shekel. The name of a weight and coin in use among the Jews. The weight of the shekel was about half an ounce in English avoirdupois weight, the value of the coin being 2*s.* 7*d.* There were two standards of the shekel: the shekel of the *sanctuary*, which was used in calculating the offerings of the temple, and all sums connected with the sacred law; and the *royal* or *profane* shekel, used for all civil payments. Various opinions are entertained respecting the relative value of these two standards; but nothing certain can be averred on the subject. Wener and Michaelis (without, however, any sufficient reason, as it appears) are of opinion that the shekel used in commercial transactions differed from both of these. (Wener, *Biblisches Realwörterbuch*, art. 'Sekel.')

Sheldrake. The common name of the species of duck called *Anas tadorna*, which is the type of the subgenus *Tadorna* of Ray and modern ornithologists. This elegant species frequents many parts of our coast, and remains throughout the year. The female commonly selects a rabbit-hole in which to deposit her eggs, which are sometimes as many as sixteen in number. The sheldrake feeds on small fish, marine insects, and sea-weed.

Shelf (A.-Sax. scylf). On Shipboard, a longitudinal timber running around the inner side of the ribs, and bolted to them as well as to the stem and sternpost. The shelves impart great longitudinal strengthening to the ship, and at the same time serve to sustain the decks.

Shell (A.-Sax. scyl). The hardening principle of shell is generally carbonate of lime nearly pure. The animal principle, in the porcellaneous shells, is a small quantity of soluble gelatine; in the mother-of-pearl shells, it is albuminous. The latter, therefore, when steeped in dilute muriatic acid, leave a membranous or cartilaginous residue; but the former are entirely soluble. For the form, structure, and mode of growth of shell, see CONCHOLOGY.

SHELL. In Artillery, a hollow projectile. A *common shell* contains a charge of powder, which is ignited at the required time by means of a fuse, and so bursts the shell, the fragments being very destructive. The fuse of a common shell is generally so arranged as to burst the shell upon its striking the object. [MARTIN'S SHELL; SEGMENT SHELL; SHRAPNEL SHELL.]

Shell Lac. [LAC.]

Shell Marl. A deposit of clay and other substances, mixed with shells, which collects at the bottom of lakes.

Shelley's Case, The Rule in. In Law, an ancient doctrine of real property law, still of great practical importance. It may be shortly stated as follows: When a person by any gift or conveyance takes an estate of freehold, and in the same gift or conveyance an estate is limited to his heirs, the words *the heirs* are words of *limitation* of the estate of the ancestor, i. e. they are considered as defining the estate or interest taken by the ancestor, and not as giving any estate or interest to the heir individually. Thus, for instance, if an estate be given to A for life, and after his death to his heirs, A will take an absolute fee simple as if the gift had been simply to him and his heirs, and the person who may be the heir of A will take nothing unless by descent or gift from A.

Shepardite. A Mineralogical synonym of Schreibersite.

Shepherd Kings. Legendary kings of Egypt, sometimes called Hycsos. According to Bunsen (*Egypt's Place in Universal History*), the conquest of Egypt by Hycsos or Amalekite invaders took place 2547 B.C., and the dynasties then established held the native princes as their tributaries for about 900 years; the rise of the eighteenth dynasty in 1625 B.C. being accompanied by the expulsion or withdrawal of the Hycsos and the bondage of the Israelites. For the value of this chronology, see SESOSTRIS. (Sir G. C. Lewis, *Astronomy of the Ancients*, ch. vi.; *Edinburgh Review*, July 1862, p. 101.)

Sherbet (a word borrowed from the Persian). A favourite beverage in the East bearing some resemblance to our lemonade, made of water, lemon juice, and sugar, with the addition of

some other ingredients, such as rose water, to give it a delightful perfume.

Sheriff (originally shire-reeve, from the Saxon, meaning the reeve or governor of the shire). The title of that functionary who acted at first only as the deputy of the earl, hence styled in Lat. *vice-comes*, but who has long been the chief civil officer in each county, where he is styled bailiff of the crown, and where he is specially intrusted with the execution of the laws and the preservation of the peace. For this purpose he has at his disposal the whole civil force of the county—in old legal language, the *posse comitatus*. The most ordinary and important functions of the sheriff, which he universally exercises by a deputy, called under-sheriff, for whose conduct he is responsible, consist in the execution of writs issuing from the superior courts, or awarded by the judges on their consent, to take effect within the county. The sheriff himself only executes in person such parts of his office as are either purely honorary, such as attendance upon the judges on circuit (for whose lodging he is also bound to provide); or as are of some dignity and public importance, such as the presiding over elections and the holding of county meetings, which it is in his power to call at any time.

Sheriffs were originally chosen by the freeholders of the county, except in some few counties where the office was hereditary, as it was in Westmoreland, till the death in 1849 of the last earl of Thanet, without issue (see stat. 13 & 14 Vict. c. 30). The system of popular election was abolished in the reign of Richard II., and sheriffs have long been appointed by the crown upon presentation of the judges, in a manner partly regulated by law, partly by custom; but sheriffs may also be nominated by the crown without recommendation of the judges, and are then familiarly styled *pocket sheriffs*. The city of London has, by charter, the right of appointing sheriffs of London and Middlesex. Those appointed in either way are bound under a penalty of 500*l.* to serve the office, except in specified cases of exemption or disability. The description given of the office in England applies to Ireland without variation, except as to the time of its origin.

Sheriff Depute. In Scotland, the principal sheriff of a county. He is named by the crown, must be an advocate of three years' standing, and receives a salary. He is entitled to name sheriff substitutes; executes writs, returns juries, &c.; decides on claims for enrollment in the county lists of parliamentary voters, and exercises a certain criminal jurisdiction. He also holds civil courts for the recovery of small debts, and a court of record, the jurisdiction of which extends to all personal actions, and possessory actions for the recovery of real property.

Sherry. A Spanish wine made from the grapes of Xeres in Andalusia. Genuine sherry is a rich dry wine, containing from 20 to 23 per cent. of alcohol: there are many varieties, and it is extensively imitated and adulterated. [WINE.]

Shew-bread. In the Old Testament. The name given to the twelve loaves of bread, one for each of the twelve tribes of Israel, which were appointed to be placed every Sabbath 'on the pure table before the Lord,' for the sustenance of the priests. They appear to be the same with the 'shew-bread' in 1 Sam. xxi., where the act of David in taking these loaves for the nourishment of himself and his followers is related.

Shiah. A Mohammedan sect who consider Ali, the fourth caliph, as the rightful successor of Mohammed, and regard his three predecessors, Abubekr, Omar, and Othman, as usurpers. The Persians belong to this division—the Mohammedans who hold that Abubekr and his two next successors were legitimate caliphs being called Sonnites.

Shibboleth (Heb. *a flood*). The name given to a test by which the Jews sought to distinguish true persons or things from false. The following account is given of the origin of this term: After the battle gained by Jephtha over the Ephraimites (Judges xii.), the Gileadites commanded by the former secured all the passes of the river; and on an Ephraimite attempting to cross, they asked him if he was of Ephraim. If he said no, they bade him pronounce the word *Shibboleth*, which the Ephraimites, from inability to give the aspirate, called *Sibboleth*; and by this means he was detected, and instantly thrown into the river. In modern times this word has been adopted into the language of politics, in which it signifies those political opinions on which all the members of a party are agreed, or the watchword by which it is intended to unite them.

Shield (A.-Sax. scyld, Ger. schild). A piece of defensive armour, very extensively used before the invention of gunpowder, and still employed by many nations among which military art has made imperfect progress. The ancient Greek shield, as described in the Homeric poems, was large and massive, sufficient to cover the man from the face to the knee, composed of leather, inlaid in some instances with metal. That of the Roman legionary was four feet high and two and a half broad, formed of wood covered with leather, and strongly guarded with bosses of iron or bronze. The ancient Britons and other nations of antiquity wore round, light, basket-like shields, often of wickerwork; more resembling the parma or lighter shield of the Romans. The Norman shield, as used in England down to the time of Henry II., was 'of the form called kite or pear-shape,' flatter at first, afterwards approaching to the semi-cylindrical. Heraldic devices were first borne on it, so far as is distinctly ascertained, in the reign of Henry II. (*Pictorial Hist. of England*, i. 640.) In that of Edward IV. the shield had become triangular: the point of the triangle was rounded off about the end of the fourteenth century. Afterwards the shape of the shield, as worn by knights, became more

and more fantastic. In actual service it fell gradually into disuse, as sword and buckler fight, the favourite pastime as well as warlike practice of former days, became obsolete after the rapier and dagger had been introduced in the reign of Elizabeth. The Highlanders carried the target with the broad sword to a much later period. (Hewitt's *Ancient Armour and Weapons in Europe.*)

SHIELDS. In Botany, little coloured cups or lines with a hard disc surrounded by a rim, and containing the fructification of lichens.

Shilling (A.-Sax. scilling, Dan. skilling). An English silver coin equal to twelve pence, or the twentieth part of a pound sterling. Among the Anglo-Saxons, the value of the shilling was only five pence; it afterwards underwent many alterations, containing sometimes sixteen pence, and often twenty pence. The period when it obtained its present value is assigned to the reign of Edward I. Many other countries besides England have a coin of this name; of these, perhaps, the Hamburg schilling is the best known. Its value is 1*d.* English.

Shiloh (Heb.). A name mentioned in the prophecy of Jacob, Genesis xlix. 10, and by some interpreters supposed to designate the Messiah; but the real meaning of the passage seems to be still a subject of controversy.

Shingle (Ger. schindel, from schinden; Lat. scindo, *to cleave*). The coarse gravel, or accumulation of small stones, found on the shores of rivers or the sea; in the latter case the term *sea-beach* is applied.

Shingles (a corruption of the French word *ceingle*, from the Lat. cingulum, *a belt*). This eruptive disorder (known to nosologists by the title of *Herpes zoster*) is generally ushered in with febrile symptoms, followed by an itching or tingling sensation of some part of the body, occasioned by patches of little red pimples, forming in the course of twenty-four hours small transparent vesicles; these succeed each other till they at length form a kind of belt round some part of the trunk or abdomen: they often form small ulcerations and scabs, continuing their progress for three or four weeks. This disorder is not contagious, and generally very slight; but in irritable habits the itching occasions want of rest and fever, and it is sometimes attended by a deep-seated pain of the affected part. The cause of shingles is generally obscure, though it may sometimes be referred to indigestion and suppressed perspiration: young persons are most subject to it. Gentle aperients and diaphoretics, strict attention to the diet, and occasional anodynes, are the only internal remedies generally required; and externally a little cold cream or fresh spermaceti ointment, or the occasional application of a very weak Goulard's lotion, is all that is necessary. [HERPES.]

SHINGLES. In Architecture, small slabs of wood, or quartered oaken boards, used instead of slates or tiles for covering churches or spires. They are sawn to a certain scantling, or rather cleft to about an inch thick at one end, and shaped like wedges, four or five inches broad and eight or nine inches long.

Ship (Ger. schiff, Gr. σκάφος, *a skiff*, from σκάπτω; Ger. schaffen; hence Eng. skipper). A general term for all large vessels, formerly restricted to such as had three complete masts; i.e. lower, top, top-gallant, and royal masts; but in modern days, when the application of steam and innumerable experiments in rigging have upset any universal principle of rig, the only limitation of the term *ship* is practically by the size of the vessel. The ship, as a whole, may be treated conveniently under four great heads; the hull, the masts and rigging, the crew, the cargo. As regards the hull, the principles for designing its shape are shown under NAVAL ARCHITECTURE; the execution of the details are described in SHIPBUILDING; the sailing gear will be found under MASTS and RIGGING. The general functions of the *personnel* are stated under their respective titles, while under various minor headings the minutiæ of a ship's equipment are fully particularised. It remains in the present article to afford some insight into the internal arrangements of the vessel.

After the hull has been completed, the ballast, which is necessary in most ships to keep them upright when under sail, is spread over the bottom of the hold, chiefly amidships, on each side of the ship's centre of gravity. In ships of war and yachts, pigs of iron compose the ballast; in merchant vessels any insufficiency in the cargo for the same purpose is met by filling with gravel or some local substitute, which can be discharged as more cargo is shipped. On the ballast are laid loose pieces of wood, called *dunnage*, on which rest the iron tanks, or casks, containing the water to drink. The hold in large ships is divided by partitions into the fore, main, and after holds. At the fore extremity, in men-of-war, are the gunner's, boatswain's, and carpenter's store rooms, containing arms, supplies of rope, bolts, pump gear, and other materials of the fittings, or for repairs. In this part also is the fore powder magazine, when there are two. In the fore hold are stowed water, wood for firing, and, separated by a strong partition, coals. In the main hold are stowed water, stores, chain cables, &c. In the after hold are the provisions; and in the *spirit room*, the spirits: here also is the powder magazine. In the narrow and shallow after extremity is stowed the bread or biscuit. The spare sails are kept in a space called the *sail room*, over the fore hold. The hemp cables are kept in the cable tiers, on a deck over the main hold. These decks immediately over the holds constitute the fore and after *cock pits*. In large ships, the whole deck is called the *orlop* deck. On the *lower* deck, which is next above the former, the men mess and sleep. In frigates and smaller vessels, this deck is the next below the upper deck; in two-deckers the main deck intervenes; in

three-deckers the main and middle decks. All these decks from the lower deck upwards are gun-decks. The above description applies to sailing vessels only; in steamers the presence of the engine room, the screw-alley, the large bunkers for coal, and other requirements, involve great and varying alterations in the internal arrangements.

In merchant ships the arrangements depend, of course, on the size of the vessel and the nature of the cargo. In all these vessels, however, the place allotted to the crew is in the fore part, and is called the *fore peak*.

Ship, Armed. In the English usages of war, a private vessel occasionally taken into the service of government in time of war, armed and equipped like a regular ship of war, and commanded by an officer of the navy.

Ship of the Line. Formerly one of the line of battle; i.e. a ship of two or more gun-decks. It is difficult to say what class of vessels in modern warfare would represent ships of the line; it is highly improbable that a battle will ever again be fought in the line order; and the French iron-sided vessels, the Magenta and Solferino, are the only specimens in existence of armoured ships of two gun-decks. The line-of-battle ship may be considered to exist only until the few remaining old ships shall be worn out.

Ship Money. The celebrated tax imposed by Charles I. without authority of parliament, which proved one of the proximate causes of the discontents that ended in the great rebellion. This device was first put in practice in 1634. It was by a writ, directed to the sheriff of every county, to provide a ship for the king's service; accompanied by written instructions, appointing a sum of money to be levied instead. This writ was framed by Attorney-General Noy. The tax was paid for about four years without opposition; when the question of its legality was raised by the refusal of Hampden to pay his share. It was argued before the judges in the Exchequer Chamber, of whom a great majority gave judgment for the crown. The Act 'whereby all the proceedings in the business of ship money were adjudged void, and disannulled, and the judgments, enrollments, and entries thereupon vacated and cancelled,' was one of the first proceedings of the Long Parliament.

It appears that, in the early ages of English history, the maritime, and perhaps some of the inland, counties were taxed specially for the supply of the king's navy, or as it was technically called *warda maris*. This regulation was only part of the general obligation laid on all tenants, however quit they were of other services, to defend the realm in case of invasion; and it might perhaps have been contested that the demand of an aid for such an emergency was exceptional, and not comprised within the rule of the great charter. But the revival of the tax at Noy's instance was a very different affair. It was levied on all counties alike, it was neither intended for, nor devoted to, the maintenance of a navy, and it was thoroughly understood to be a device for taxing the nation without its consent, in the interest of the court, and with a view to coercing the national liberties.

Ship Pendulum. A pendulum used in the navy to ascertain the *heel* of a vessel, so that allowance may be made, in laying a gun, for the inclination of the deck.

Ships, Registry of. In Commercial Navigation, the registration or enrollment of ships at the custom-house, so as to entitle them to be classed among, and to enjoy the privileges of, British-built ships.

The registry of ships appears to have been first introduced into this country by the Navigation Act (12 Ch. II. c. 18, A.D. 1660), and was provided for by a series of subsequent statutory regulations, now embodied in the Merchant Shipping Act 1854 and amending Acts.

The great and perhaps the only original object of the registration of ships, was to facilitate the exclusion of foreign ships from those departments in which they were prohibited from engaging by the navigation laws, by affording a ready means of distinguishing such as were really British. It has also been considered advantageous to individuals, by preventing the fraudulent assignment of property in ships; but Lord Tenterden has observed, in reference to this supposed advantage, that 'the instances in which fair and honest transactions are rendered unavailable, through a negligent want of compliance with the forms directed by these and other statutes requiring a public register of conveyances, made the expediency of all such regulations, considered with reference to private benefit only, a matter of question and controversy.' (*Law of Shipping*, part i. c. ii.)

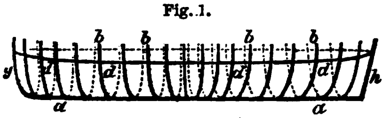
Shipbuilding. The application, in practice, of the theoretical design developed by the naval architect. The principles which should regulate the choice of a ship's form and dimensions are laid down in the article NAVAL ARCHITECTURE. The shipwright has three detailed plans delivered to him—the sheer plan, the half-breadth plan, and the body plan. From these plans he has to work, and to produce a structure corresponding exactly in shape, size, and strength, to that delineated by the naval architect. Whatever the material of which the ship is to be constructed, the external form will be the same, though the internal strengthening differs in each case. Building in wood is conducted in quite a different manner from building in iron, and therefore it will be necessary to consider them separately. Wooden vessels are built for all purposes; ships of thin iron-plate for the ordinary carriage of passengers and freight; while armour-plated vessels are almost invulnerable ships intended for warfare with heavy modern artillery. These three constructions need separate description. As the oldest, as yet the

commonest, and the most complicated, the wooden ship shall first be dealt with.

A ship may be described as a hollow box, in shape approaching an elongated rectangle; though for reasons of speed the solid angles are reduced to curved surfaces. It is made to bear heavy burdens, so heavy that if water were to come in in any large quantity the structure would sink. Yet it is at the mercy of an element of gigantic power and fearful violence. Immense strength and solidarity are therefore requisite to keep the water out. Could the form be circular, or even square, this might be comparatively easy, but speed is an essential concurrently with carrying power. Every effort towards locomotion tends to produce disruption in the structure. The length must many times exceed the breadth; fracture sideways becomes imminent. The length involves frequent suspension on two waves, or balancing on one; *separation lengthwise* is to be dreaded. Is motion sought from the wind? A vast spread of canvas, acted on by the storm, tends to submerge the prow, which the hull's buoyancy counteracts by pressure in another, but not an opposite, direction. Under this conflict of force every timber strains. Is steam the motive power? Motion is obtained by rapid and strong blows upon the water. Every blow makes the whole ship vibrate, and loosens that caulking by which alone the timbers can be watertight. These difficulties will show that the shipbuilder has *by skill to* render vastly strong a form in which weakness is a necessary constituent. A long narrow box is obviously a weak form. It is only by much internal bracing that it can be rendered strong; and this internal bracing must be so contrived that it shall interfere as little as possible with the stowage room and the facility of communication inboard.

Figs. 1 and 2 are intended to show in an elementary manner the combination by which

Fig. 1.



strength is secured. The *keel a* is a massive beam, forming as it were the backbone of the ship. Across it are laid the flat and lower ends of the ribs or timbers *b*, which support the sides. On the floor formed by these cross-pieces is laid the *keelson c*, an inner beam similar to the keel. The keelson is firmly bolted through the cross-pieces to the keel, thus holding the ribs at their bases the relative distances apart. Within the ship, on the inside of the ribs, a strong timber (*d*) called the *shelf* is bolted from stem to stern. This retains the ribs in a parallel position, and at the same time supports the *deck e*. The deck, being slightly arched to prevent it from sinking in the middle under heavy burdens, has a tendency to force the vessel's sides outwards. This is prevented by the employment of knees, *f*, which are brackets—now most commonly of iron, but formerly of wood grown for the purpose. These knees hold the ribs to the cross-beam on which the deck rests. The beam thus has double functions. Through the knees it holds the sides together; and by its rigidity it prevents the ship being crushed inwards by the violence of the waves. From the respective ends of the keel rise the *stem g* and *stern-post h*. At these points the ship's *beam* or width is the thickness of the post only. The pairs of ribs gradually become wider in their compass, till the widest part of the ship is reached. The ribs or timbers near the stem and stern are set at angles less than right angles to the keel, as shown in fig. 3, in which the spectator is supposed to look down from above. The parts of the vessel in which these ribs are thus obliquely set constitute the *cant bodies*. The ribs being bolted at the proper distance or *room and space* apart, the intervening space is occupied by *fillings in*, i.e. by timbers, somewhat less thick, jammed tightly between to a point above the watermark. This gives solidity to the structure. After the filling in, the *planking* is bolted on to the ribs within and without, being *rabbeted* into the keel below and into the stem and stern-post at the ends. It may now be useful to survey the elements of strength which have been arrived at. The keel, keelson, shelves, and planking, bind stem to stern, and give strength in the direction of the length. At bottom, the bolts through keel and keelson, and, higher up, the knees acting on the beams, maintain the width. There remains weakness in the direction of the depth, for each rib of necessity consists of several pieces, joined one above the other. The planking does not offer much resistance to a longitudinal separation. Strength in this particular is obtained by *diagonal trussing* within, either in wood or, preferably, iron-plate. It consists of bands bolted each to several ribs at an angle of about 45°.

Fig. 2.

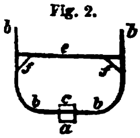


Fig. 3.

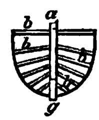


Having thus described in general terms the system on which a wooden vessel is constructed, it is unnecessary in the present article to enter into a minute description of the component parts, as each will be found described under its name. It is proper, however, to observe that in all parallel work, as the floors, the planking, &c., care is taken so to distribute the joints that they shall be a minimum cause of weakness. The greater timbers, as the keel, keelson, and ribs, cannot be obtained in one length. Their parts are then joined by scarfs, coaks, dowels, or chocks.

Iron Shipbuilding.—Although the relative durability of wood and iron as materials for shipbuilding is still a disputed point, and must so remain for many future years, it has been settled definitely that, while in actual use, iron possesses many advantages over wood; size for

size, the iron ship is far lighter; weight for weight, she has greater strength. From the ease with which wrought iron can be rolled into any shape, the curves of the vessel's form are obtained without the cumbrous complications of timber necessary in wooden building.

Following the former simile of the oblong box, the iron vessel may be looked upon as a tubular girder closed at both ends. The nomenclature of the parts is the same as in the wooden ship; but there, except in outward form, the resemblance ends. The structure is, or should be, mutually supporting throughout; the keel therefore ceases to be of the same vital consequence as in wood, and is retained rather in aid of sailing qualities than to give strength. It is usually composed of boiler-plates strongly riveted together. Rising from it, and riveted to it on either side, are the ribs, which are usually *made* girders. These are covered (to represent the planking) with large sheets of boiler-plate, riveted together at the edges, of a thickness varying from $\frac{5}{16}$ to $\frac{15}{16}$ of an inch. In large and fine ships, an inner skin of iron is laid within the girder-ribs. Where this arrangement is adopted, there is a series of air-compartments (separated from each other by the ribs) all round the vessel, which aid flotation in the ordinary way, and in the event of accident offer the obstacle of a second skin to the entrance of water. The ribs are held together and apart by beams of I iron. Over these, thin iron plates are fastened, and above these plates wooden planks, which form the several decks. It is becoming a recognised datum that in an iron ship the strength of the deck is as important as that of the bottom; the deck being the upper, as the bottom is the lower, transverse strength of the girder formed by the whole ship. An additional security is afforded by *watertight bulkheads*, which are diaphragms of iron stretched across the ship at intervals from deck to keel, and provided with watertight doors of communication. The bulkheads divide the vessel into completely separate compartments, a few of which suffice to float it, when from any mishap the others become filled with water. Many vessels have owed their safety during ocean voyages to their watertight compartments. The greatest drawback in the case of iron vessels is the rapidity with which the bottom fouls from the adhesion of marine animals and plants. The fouling speedily destroys speed. Many compositions for coating the bottom to prevent fouling have been tried, but without permanent success. Vitreous plates have answered well. In the best modern vessels the following plan has been adopted: thin wooden planking is bolted by iron screws to the ship's bottom; on this another coat of planking is fastened by copper screws, care being taken that the iron and copper do not communicate. Outside the second line of planking the ordinary copper sheathing is made fast. By this process galvanic action between the copper and iron is precluded. There are numerous details in iron shipbuilding, as the arrangement of the girders, the beams, ties, &c., which vary continually, according to the principles or fancy of the naval architect, the purpose of the vessel, and the strength requisite for the seas which she is to navigate.

Ships of Iron and Wood.—Among modern shipbuilders iron has been frequently introduced in the internal arrangements of wooden hulls, as in the tie-beams, the inner planking, &c. Its use is advantageous, from the saving of space and weight effected without diminution of strength. Several builders have also affected a great saving in these respects by using iron girders for the ribs and covering them without with wooden planking.

Armour-plated Vessels.—Under the article Iron Armour Plate, a brief sketch has been given of the gradual introduction of iron armour as a defence in ships of war against the ponderous artillery of the present day. The conditions of strength as regards the armour have been detailed in that article: it is only necessary now to advert to the several builds which have been adopted or, perhaps more correctly, tried. It must, however, be premised that the ship and her armour are quite distinct: the armour being merely a defensive wrapper hung on, and contributing not in the least to the strength of the vessel as a sea-boat. The earliest specimens, of which the French 'Gloire' and British 'Warrior' are types, were simply large frigates of the most massive construction, clad in armour at the sides, the armour consisting of 4½ inches of iron on 18 inches of oak or teak. Many such vessels have been built; the hulls of some being of wood, those of others of iron. On a balance of advantages the preference is given to iron. The armour usually covers only the part of the broadside where the guns are, the bow and stern being without armour, except for a depth of perhaps four feet above and below the waterline. Watertight bulkheads are provided to secure safety if the bow or stern be pierced. When the ship is to act as a ram, an additional spur is often riveted over the edge and point of the ordinary stem to form a more powerful beak. After a charge this beak may be carried away, but the ship's stem ought to remain intact.

But the best armour, if struck very often by heavy steel projectiles, will be destroyed. The larger the surface which a ship presents to the enemy, the greater is her chance of destruction; it therefore occurred early to competitive inventors—among the foremost of whom were Timby and Ericsson, of the United States, and Captain Cowper Coles, of the British navy—to reduce the hull of the vessel to a mere platform, scarcely above the level of the water, and to carry the guns in a tower or towers. The Confederate Americans produced the Merrimac and Tennessee, two rams of this class, containing their armament in a raised fort, with sloping sides, which stood in the midst of

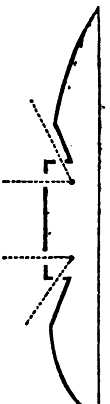
the deck; this fort was a fixture. The Federal Americans opposed it by a class of vessels, called 'Monitors,' from the name of the first so built, which mounted one or two enormous guns in a *revolving* turret, wholly above the deck. These offered a small mark to the hostile artillery; the turret was turned with ease by the steam engine, which also provided ventilation. The guns could be turned out of fire while loading, and could range in any direction when loaded. On the whole, they were considered a great improvement, and admirably adapted for river or harbour defence; but they were bad sea-boats, and the original Monitor went down head-first in a gale. It is fair, however, to say that in June 1866, the Miantonomoh, an American Monitor of improved build and heavy armament, crossed the Atlantic without difficulty, the Monadnock having previously successfully weathered the Horn.

Concurrently with the rise of the Monitors, Captain Coles has urged upon the British government the adoption of *turret ships*, which, like the Monitors, have revolving turrets, sunk, however, below the deck, with the exception of just sufficient height for the discharge of the guns. They differ from the American model in being sea-going masted vessels. The Royal Sovereign was altered from a wooden line-of-battle ship to a turret ship; but her former build prevented the full adoption of Captain Coles' principles. Her sides are plated with five-and-a-half inch iron, her deck with a less thickness. The turrets, of which she has four, are of five-inch iron, increased to ten inches near the embrasures; at all points there is a thick wood backing to the iron. Notwithstanding her defects, the Royal Sovereign has been pronounced admirably seaworthy, and her commanding officer has declared that, taken all for all, she is the most formidable vessel afloat. In June 1866, one of her turrets was experimented on with heavy shot at short range. At the close of the trial it was found to revolve with the same ease as at the beginning. A fundamental difference between the American and the British turrets, besides their respective heights above the deck, is that the former revolves, by the aid of the engine, on a central pivot based on the keel, while the latter is easily moved by a hand-winch on rollers under its periphery. It is impossible to doubt the superiority of the British plan, as regards both handiness and distribution of weight. The question of the comparative advantage of broadside and turret armoured vessels has been debated with vigour and acrimony for five years, and numerous scientific committees have reported on the subject. The general conclusion appears to be, that the turret vessel has the advantage for all purposes except fast cruisers, which require for various reasons sides and decks of the ordinary height. The advantages claimed for the turret are:—

1. That it is the best mode of carrying very heavy guns: (*a*) because their weight acts at less leverage and less destructively to the ship; (*b*) because there is a steadier platform from which to fire.
2. That it gives the best range: (*a*) because it is higher above the water than in a broadside; (*b*) because the direction in which it can be trained is only limited by the obstructions on the deck.
3. That the gunners and gun are safer: because during loading the port can in most cases be turned out of fire.
4. That it allows of greater rapidity of fire: because the gun can be kept always directed to the mark aimed at.
5. That it throws greater weight of metal on one side than is otherwise possible.
6. That it gives advantage of position, inasmuch as the turret vessel can keep her head in any direction most convenient.
7. That it allows of correct aiming concurrently with narrow portholes.

As the best specimens in the British navy of these rival classes, may be mentioned, for broadside ironclads, the Bellerophon, which has a powerful broadside; the Pallas, which has guns capable of being trained fore and aft, as well as to the broadside, her side being constructed, as in the annexed diagram, on the level of the portholes; and the Minotaur, a stupendous five-masted frigate, ironclad throughout. For turret vessels, the Royal Sovereign is a fine ship, but of wood; the Wyvern and Scorpion are smaller vessels, of iron, and very efficient; the Waterwitch, of 800 tons, is intended as a sort of turret gunboat, propelled by the ejection of water.

Fig. 4.



Approximate half-breadth plan of Pallas on the level of the portholes.

In foreign navies, the same models as in the British navy have been more or less followed, the American chiefly trusting to Monitors, the French to broadside ships, and among them having two two-deckers, the only specimens (and those not encouraging) of such ships among ironclads.

Shire (from A.-Sax. scyran, *to divide*; whence the verb *to sheer*). A territorial division. In modern language, *shire* is synonymous with *county*; but some smaller districts in the north of England retain the provincial appellation of shires: as Richmondshire, in the North Riding of Yorkshire; Hallamshire, or the manor of Hallam, in the West Riding, which is nearly coextensive with the parish of Sheffield. [COUNTY.]

Shire Clerk. An officer appointed by the sheriff to assist in keeping the county court.

Shire Mote. In Ancient English Law, the *shire meeting*, i.e. sheriff's court.

Shirt of Need. In the ages of chivalry, a garment, called by the Germans *nothhemd*, which was supposed to render the wearer proof against all wounds.

Shiva. [SIVA.]

Shoddy. A kind of woollen cloth, made from an inferior species of material, such as old stockings, flannel, and other soft goods. Its origin dates back as far as 1813, but it was long regarded as a dishonest production. The old goods are torn up into their original fibres by cylindrical machines armed with teeth, and reworked up. The price of ordinary shoddy varies from ¾*d.* to 5*d.* per lb., and the white from 2*d.* to 10*d.* Some goods, such as pea-jackets and low-coloured blankets, are made with only one part of pure wool to six parts of shoddy. [MUNGO.]

Shoe (Ger. schuh). A covering for the foot, usually made of leather. Among the Jews these coverings were made not only of leather, but of linen, wood, and, for soldiers, sometimes of brass and iron. The Roman shoe, or *calceus*, covered the whole foot, and was tied above with strings, being thus distinguished from the sandal or *solea*. The fashion of long points is the most singular feature in the history of mediæval shoes. These long-pointed shoes were called *crackowes*, and were tied by chains to the knee. An Act of Parliament in 1463 forbade the use and manufacture of such shoes; but the prohibition was ineffectual, and recourse was had to the excommunication of those who wore shoes with points exceeding two inches in length.

Shoemakers' Black. *Atramentum sutorium.* A name given by Pliny to sulphate of iron, or green vitriol, from the circumstance of its being used to rub over tanned leather, to which it communicates a black dye.

Shooting Stars. The article METEORS, LUMINOUS, contains a general résumé of our present knowledge of the phenomena among which shooting stars are included. In this place, therefore, we need only deal somewhat with the early history, and some of the more interesting details.

The apparent magnitudes of shooting stars are widely different. The greater part of them may be classed of the 3rd, 4th, 5th, and 6th magnitudes; but some occur which surpass stars of the 1st magnitude, and even exceed Jupiter and Venus in brilliancy. In some of them the globular form can be easily recognised; and, in fact, it is impossible, from their appearances, to make any distinction between the larger shooting stars and the smaller individuals of the class of meteors to which the name of FIRE-BALLS or *bolides* is usually appropriated.

Some of the shooting stars leave a luminous train behind them, which marks their path through the sky with a milk-white light. These trains for the most part disappear in a few seconds; but sometimes they continue longer, and even for several minutes. In the case of actual fire-balls, Dr. Olbers observed trains which continued from six to seven minutes; and Brandes, in one instance, estimated that fifteen minutes elapsed between the extinction of the fire-ball and the disappearance of the luminous train. The trains in general assume the form of a cylinder, the interior of which is void of luminous matter; and not unfrequently, before their disappearance, they take a curved form. The most probable explanation was held to be, that they were caused by finely divided solid and phosphorescent matter left behind by the meteor, and bent by currents of air. This explanation of the latter phenomenon has been placed almost beyond all doubt by the observations of M. Coulvier Gravier.

The older philosophers had formed various theories to explain these remarkable phenomena. By some they were supposed to be the products of an oily sulphurous vapour existing in the atmosphere, which being disposed in thin layers, and becoming inflamed by some means, would exhibit the appearance of a clear brilliant spark passing rapidly from one point to another. About the middle of the last century, when the effects and phenomena of electricity began to be better understood, Beccaria and Vassali, among others, regarded the shooting stars as merely electrical sparks; an hypothesis which was soon shown to be untenable. At a later period, when the inflammable nature of the gases became known, Lavoisier, Volta, Herbert, Toaldo, Gren, and others, referred these meteors to hydrogen gas, which, by reason of its inferior density, they supposed must be accumulated in the higher regions of the atmosphere. Dalton, however, showed that such accumulation cannot take place, inasmuch as all the gases which constitute the atmosphere must be equally diffused through its whole extent, according to the law of Mariotte. Deluc maintained that certain phosphoric exhalations generated in the earth, and becoming inflamed in the sky, formed the true essence of the shooting stars.

In this state the subject remained when Chladni published his celebrated work on the causes of the masses of iron and other similar substances found in Siberia by Pallas, in which he clearly established, by comparing the circumstances of a great multitude of observations, that fire-balls are meteors having their origin beyond our atmosphere; that, in fact, they are masses of nebulous matter moving in space with planetary velocities, which, when they come in the way of the earth in its revolution about the sun, and enter the atmosphere, are inflamed by its resistance and friction, and become luminous, sometimes scattering masses of stone and iron on the ground. Halley, Wallis, Pringle, Maskelyne, and others, had previously assigned a cosmical origin to these meteors, but without suspecting that masses of stone and iron fell from them. The close resemblance which the greater part of the shooting stars present to fire-balls, at once induced Chladni to consider these phenomena also as cosmical; that is to say, as small masses

of matter not having their origin in our atmosphere, but entering it from without, and which are either entirely consumed in it, or become extinguished when they have passed beyond it.

These conclusions, however, required to be confirmed by a more accurate investigation of the phenomena; for as yet no exact determination had been made of the actual average heights of the shooting stars above the earth, or of their orbits, velocities, or magnitudes. In the year 1798 this important but difficult enquiry was undertaken by Professors Brandes of Leipsig, and Benzenberg of Düsseldorf (both at that time students in Göttingen). Having selected a base line (about nine miles in length), they placed themselves at its extremities on appointed nights, and observed all the shooting stars which appeared, tracing their courses through the heavens on a celestial map, and noting the instants of their appearances and extinctions by chronometers previously compared. The differences of the paths traced on the maps afforded data for the determination of the parallaxes, and consequently the heights and the lengths of the orbits. On six evenings, between September and November, the whole number of shooting stars seen by both observers was 402; of these 22 were identified as having been observed by each in such a manner that the altitude of the meteor above the ground at the instant of extinction could be computed. The least of the altitudes was about 6 English miles. Of the whole there were 7 under 45 miles; 9 between 45 and 90; 6 above 90; and the highest was above 140 miles. There were only two observed so completely as to afford data for determining the velocity. The first gave 25 miles, and the second from 17 to 21 miles in a second. The most remarkable result was, that one of them certainly was observed not to *fall*, but to move in a direction away from the earth.

By these observations a precise idea was first obtained of the altitudes, distances, and velocities of these singular meteors. A similar but more extended plan of observation was organised by Brandes, in 1823, and carried into effect at Breslau and the neighbouring towns, by a considerable number of persons observing at the same time on concerted nights. Between April and October about 1,800 shooting stars were noted at the different places; out of which number 62 were found which had been observed simultaneously at more than one station in such a manner that their respective altitudes could be determined, and 36 others of which the observations furnished data for estimating the entire orbits. Of these 98, the heights (at the time of extinction) of 4 were computed to be under 15 English miles; of 15 between 15 and 30 miles; of 22 between 30 and 45; of 33 between 45 and 70; of 13 between 70 and 90; and of 11 above 90 miles. Of these last two had an altitude of about 140 miles, one of 220 miles, one of 280, and there was one of which the height was estimated to exceed 460 miles.

Of the 36 computed orbits, in 26 instances the motion was downwards, in one case horizontal, and in the remaining 9 more or less upwards. The velocities were between 18 and 36 miles in a second. The trajectories were frequently not straight lines, but curved sometimes in the horizontal and sometimes in the vertical direction, and sometimes they were of a serpentine form. The predominating direction of the motion of the meteors from north-east to south-west, contrary to that of the earth in its orbit, was very remarkable, and is important in reference to the theory of their physical origin.

A similar set of observations was made in Belgium in 1824, under the direction of M. Quetelet, the results of which are published in the *Annuaire de Bruxelles* for 1837. M. Quetelet was chiefly solicitous to determine the velocity of the meteors. He obtained six corresponding observations from which this element could be deduced, and the results varied from ten to twenty-five English miles in a second. The mean of the six results gave a velocity of nearly seventeen miles per second, a little less than that of the earth in its orbit.

Another set of corresponding observations was made in Switzerland on August 10, 1838; a circumstantial account of which is given by M. Wartmann in Quetelet's *Correspondance Mathématique* for July 1839. M. Wartmann and five other observers, provided with celestial charts, stationed themselves at the observatory of Geneva; and the corresponding observations were made at Planchettes, a village about sixty miles to the north-east of that city. In the space of seven and a half hours, the number of meteors noted by the six observers at Geneva was 381; and during five and a half hours, the number observed at Planchettes by two observers was 104. All the circumstances of the phenomena—the place of the apparition and disappearance of each meteor, the time during which it continued visible, its brightness relatively to the fixed stars, whether accompanied with a train, &c.—were carefully noted, and the trajectories projected on a large planisphere. The extent of the trajectories described by the meteors was very different, varying from 8° to 70° of angular space. The velocities appeared also to differ considerably; but the average velocity was supposed by M. Wartmann to be 25° per second. It was found, from the comparison of the simultaneous observations, that the average height above the ground was about 550 miles; and hence the relative velocity was computed to be about 240 miles in a second. But as the greater number moved in a direction opposite to that of the earth in its orbit, the relative velocity must be diminished by the earth's velocity (about 19 miles in a second). This still leaves upwards of 220 miles per second for the absolute velocity of the meteor, which is more than eleven times the orbital velocity of the earth, seven and a half times that of the planet Mercury, and probably greater than that of the comets at their perihelia.

Such are the principal facts which were early established respecting the heights, velocities, and orbits of the shooting stars; and it is from these, and others lately made which confirm them, that we have been enabled to form any probable conjectures respecting their origin.

The early theories, as already stated, ascribed an atmospheric origin both to shooting stars and fire-balls; but, although there is little doubt that shooting stars do not become visible until they are immersed in our atmosphere, yet the supposition of the atmospheric origin of these meteors is on other grounds altogether untenable.

Another hypothesis respecting their origin was, that they are bodies projected to our earth from volcanoes in the moon. Dr. Olbers was the first, perhaps, who showed the possibility of this hypothesis. On computing the forces necessary to overcome the moon's attraction, he found that a body projected from the moon with a velocity of about 8,500 feet in a second would not fall back on the lunar surface, but recede from it indefinitely; and that in order to reach the earth it is only necessary that the projectile should have the velocity of 8,300 feet, which is quite conceivable, being only about four or five times that of a cannon-ball. The hypothesis of the lunar origin of meteoric stones was adopted by Laplace, Berzelius, Benzenberg, and others; but the observed velocities of the shooting stars have rendered this origin extremely improbable with respect to them. In order to enter our atmosphere with a velocity of 20 miles in a second, it may be shown that if they come from the moon they must have been projected from the lunar surface with a velocity of about 120,000 feet in a second, which may be regarded as altogether impossible.

It thus appears that those shooting stars and fire-balls which have the planetary velocity of from 20 to 40 miles in a second, cannot with any probability be regarded as having their origin in the moon. Whether any individual bodies moving with a smaller velocity may have a lunar origin, is a question which cannot be decisively answered. 'To me,' says Dr. Olbers, 'it does not appear at all probable; and I regard the moon, in its present circumstances, as an extremely peaceable neighbour, which, from its want of water and atmosphere, is no longer capable of any strong explosions.'

Another hypothesis, suggested by Chladni, has now for some time met with gradually increasing favour. It consists in supposing that, independently of the great planets, there exist in the planetary regions myriads of small bodies which circulate about the sun, generally in groups of zones; and that some of these zones intersect the ecliptic, and are consequently encountered by the earth in its annual revolution.

Speaking of this hypothesis, which is now accepted on all hands, Mr. Joule says: 'Its likelihood will be rendered evident if we suppose a meteoric stone, of the size of a six-inch cube, to enter our atmosphere at the rate of eighteen miles per second of time, the atmosphere being $\frac{1}{160}$ of its density at the earth's surface. The resistance offered to the motion of the stone will, in this case, be at least 51,600 lbs.; and if the stone traverse twenty miles with this amount of resistance, sufficient heat will thereby be developed to give 1° Fahrenheit to 6,967,980 lbs. of water. Of course by far the largest portion of this heat will be given to the displaced air, every particle of which will sustain the shock, whilst only the surface of the stone will be in violent collision with the atmosphere. Hence the stone may be considered as placed in a blast of intensely heated air, the heat being communicated from the surface to the centre by conduction. Only a small portion of the heat evolved will therefore be received by the stone; but if we estimate it at only $\frac{1}{100}$, it will still be equal to 1° Fahrenheit per 69,679 lbs. of water, a quantity quite equal to the melting and dissipation of any materials of which it may be composed.

The dissolution of the stone will also be accelerated in most cases by its breaking into pieces, in consequence of the unequal resistance experienced by different parts of its surface, especially after its cohesion has been partially overcome by heat.

It appears that the varied phenomena of meteoric stones and shooting stars may all be explained in the above manner; and that the different velocities of the meteorolites, varying from four to forty miles per second, according to the direction of their motions with respect to the earth, along with their various sizes, will suffice to show why some of these bodies are destroyed the instant they arrive in our atmosphere, and why others, with diminished velocity, arrive at the earth's surface.

The presumptions in favour of the cosmical origin of the shooting stars are founded chiefly on their periodical recurrence at certain epochs of the year, and the extraordinary displays of the phenomena in various years on the nights of the 12th or 13th of November. We shall here merely state the principal circumstances accompanying those of 1799, which put the notion of a *lunar* origin entirely out of the question.

On the morning of the 12th of November, 1799, before sunrise, Humboldt and Bonpland, then on the coast of Mexico, were witnesses to a remarkable exhibition of shooting stars and fire-balls. They filled the part of the heavens extending from due east to about 30° towards the north and south. They rose from the horizon between the east and east-north-east points, described arcs of unequal magnitude, and fell towards the south; some of them rose to the height of 40°, all above 25° or 30°. Many of them appeared to explode, but the larger number disappeared without emitting sparks: some had a nucleus apparently equal to Jupiter. This most remarkable spectacle was seen at the same time in Cumana, on the

borders of Brazil, in French Guiana, in the channel of Bahama, on the continent of North America, in Labrador, and in Greenland; and even at Carlsruhe, Halle, and other places in Germany, many shooting stars were seen on the same day. At Nain and Hoffenthal in Labrador, and at Neuhernhut and Lichtenau in Greenland, the meteors seem to have approached the nearest to the earth. At Nain they fell towards all points of the horizon; and some of them had a diameter which the spectators estimated at half an ell. (Humboldt's *Recueil des Voyages, &c.* vol. ii.)

The second great meteoric epoch is the 10th of August, first pointed out by M. Quetelet; and although no displays similar to those of the November period have been witnessed on this night, there are more instances of the recurrence of the phenomena. In the three years 1838, 1839, 1840, shooting stars were observed in great numbers both on the 9th and 10th; but they appear in general to be unusually abundant during the two first weeks of August. The other periods which have been remarked are the 18th of October, the 23rd or 24th of April, the 6th and 7th of December, the nights from the 15th to the 20th of June, and the 2nd of January.

Halley first suggested the idea that the shooting stars may be observed as signals for determining differences of longitude by simultaneous observations; and Maskelyne in 1783 published a paper on the subject, in which he calls the attention of astronomers to the phenomena, and distinctly points out this application. The idea was revived by Benzenberg in 1802; but so long as they were regarded merely as casual phenomena, it could scarcely be hoped that they would be of much use in this respect to practical astronomy. As soon, however, as their periodicity became probable, the phenomena acquired a new interest; and some recent attempts to determine longitudes in this manner have proved that the method is not to be disregarded. In fact, most of our most recent knowledge of the star-showers has been acquired by systematic observation of them at places some distance apart, telegraphically connected. See an interesting paper on this subject by Dr. Olbers, in Schumacher's *Jahrbuch* for 1837; also the *Annuaire du Bureau des Longitudes* for 1836; *Mém. de l'Acad. de Bruxelles* for 1838; Schumacher's *Astronomische Nachrichten*, vols. xvi. and xvii.; and general papers communicated during 1863, 1864, and 1865, by Mr. Newton to *Silliman's Journal*, and by Mr. Herschel to the *Monthly Notices of the Astronomical Society*.

Shore. In Architecture, a piece of timber or other material placed in such a direction as to prop up a wall or other heavy body.

Shorea (after Sir J. Shore, governor-general of Bengal). This tropical Asiatic genus belongs to the order *Dipteraceæ*, and consists of large resinous trees, with entire or wavy-edged leaves, and axillary and terminal panicles of sweet-smelling yellow flowers. *S. robusta*, the Saul or Sál, is a native of India, extending from the provinces of Bengal and Behar to the foot of the Himalayas within the limits of the tropics. It is a magnificent and most important timber-tree, frequently attaining a height of upwards of a hundred feet. The wood is of a light-brown colour, close-grained, strong and durable, and is extensively employed in India, both by the natives and by Europeans, for shipbuilding, engineering, and other purposes where great strength and toughness are requisite. It is stronger, and at the same time much heavier than Indian teak. An oil is obtained from the seeds. Part of the resin known as Dammar is likewise obtained from this and other species of *Shorea*.

Shores (Dutch schoor). Strong props, used in shipbuilding, to keep the vessel steady on the slip. They are placed under the wales of the ship's bottom. *Breast-shores* are similar props used when a completed vessel is docked.

Short Page. In Printing, a page short of its full quantity of matter, such as those at the ends of chapters, or at the end of a book.

Shorthand Writing. [STENOGRAPHY.]

Shortstuff. In Shipbuilding, thin planks fastened over the ribs on the inside between the portholes.

Shot (A.-Sax. scyt). Any solid PROJECTILE.

Shot Lockers. Long pieces of wood pierced with holes like cups, in which the shot are placed, along the sides and round the hatchways.

Shoulder (A.-Sax. sculdre, Ger. schulter). In Fortification, the angle of a bastion included between the face and flank.

Shoulder Blade. The *scapula*, or pleurapophysial element of the pectoral arch.

Shoulder-of-Mutton Sail. A triangular sail used in small vessels as an auxiliary to prevent leeway. It is mounted on a temporary mast at the stern, its base being extended on a beam, and its apex against the mast. No gaff is employed.

Shoveller. The name of a species of duck, remarkable for the length and terminal expansion of the shovel-like bill; whence the name of *Spathulea*, proposed for the subgenus of which it is the type. It is the *Anas clypeata* of Linnæus.

Shrapnel Shells. In Artillery, a shell invented by General Shrapnel of the Royal Artillery. The projectile originally consisted of a thin iron shell filled with balls, sufficient powder being inserted with the balls to cause, when ignited by the fuse, the bursting of the shell; it was designed to act as case or grape at longer range than was attainable by those projectiles. Hence it was also called *spherical case shot*. The essence of the shell's construction is that the bursting charge should be so small as merely to open the shell, allowing the bullets to continue in flight with unimpeded velocity. *Improved Shrapnel shells* had the bursting charge separated from the balls by being placed in a cylinder in the middle of the shell. In the *diaphragm Shrapnel shell* the

powder is separated by an iron diaphragm from the bullets, all space between which is filled up with coal-dust. Shrapnel shells should burst about fifty yards short of the object, and should not be fired at very long ranges, or the bullets will not have sufficient velocity. .

Shrew. A small insectivorous mammal, some species of which are aquatic. [SOREX.]

Shrike. A name for the *Butcher birds*, or species of *Lanius*.

Shrine (Ger. schrein; Lat. scrinium, *a desk or cabinet*; whence also *screen*). Properly, the receptacle of the remains or relics of a saint. Shrines are of two sorts: portable, used in processions, called in Latin *feretra*; and fixed in churches. The appropriate place for shrines, in the churches of the middle ages, was generally in the eastern part, in the space behind the high altar. Such is the situation of the celebrated shrine of the three kings of Cologne; and such was that of the shrines at St. Albans, Canterbury, Durham, and Westminster, before the Reformation. (*Archæologia*, vol. i.)

Shrouds (A.-Sax. scrud). The large ropes supporting a mast laterally; they take the names of their respective masts, as *main-shrouds, fore-topmast-shrouds, mizen-topgallant shrouds*, &c.

Shrove Tuesday. The Tuesday after Quinquagesima Sunday, and immediately preceding Ash Wednesday; so called from the Anglo-Sax. shriven, *to confess*, because on that day confession was made preparatory to the fast of Lent.

Shrub (A.-Sax. scrob, Ger. schroff, *rough*). In Botany, a small low dwarfish tree, which, instead of one single stem, frequently puts forth from the same root several sets or stems.

SHRUB. The name given to a species of sweet wine or liqueur, of which rum forms the chief ingredient.

Shuttle (Icelandic skutul). An instrument used by weavers, which guides the thread it contains, so as to make it form the woofs of stuffs, cloths, linen, and other fabrics, by throwing the shuttle alternately from left to right and from right to left across between the threads of the warp, which are stretched out lengthwise on the loom. In the middle of the shuttle is a kind of cavity, called its eye or chamber, in which is enclosed the *spoul*, which is part of the thread destined for the woof.

Shwan Pan. The calculating instrument of the Chinese. It is similar in shape and construction to the Roman abacus, and is used in the same manner. [ABACUS.]

Si. In Music, the French and Italian name for the seventh sound, added by Le Maire, a Frenchman, at the latter end of the seventeenth century, to the six ancient notes, ut, re, mi, fa, sol, la, of Guido. It corresponds to our B.

Sialagogue (Gr. σίαλον, *saliva*; ἀγωγός, *a leader*). Medicines which increase the flow of saliva.

Sibbens. A disease endemic in some of the western parts of Scotland, somewhat resembling the yaws, and propagated by direct application of the contagious matter.

Siberite. A synonym of Rubellite or Red Tourmaline, the finest specimens of which have been found in Siberia.

Sibyl (Gr. Σίβυλλα). The name given to certain prophetic women said to have lived in Greece and Italy. Some authors recount as many as ten of them. The most celebrated were the Sibyl of Cumæ, fabled to have been consulted by Æneas, and the prophetess who is said to have offered her books to Tarquin the Proud. (*Mém. de l'Acad. des Inscr.* vol. xxiii.)

Sibylline Books. Documents supposed to contain the fate of the Roman empire. Nine of them are said to have been offered by an old woman, called Amalthæa, to Tarquin the Proud; but Tarquin refusing to give the price which she asked, she went away, and burnt three of them. Returning with the remainder, she offered them to the king on the same terms as before; and on his second refusal departed again, and returned with three, which she still offered at the same price as the original nine. The king, struck with her conduct, at last acceded to her offer, and intrusted the care of the books to certain priests (the quindecemviri). The story runs that they were preserved in a stone chest beneath the temple of Jupiter Capitolinus, being consulted in times of public danger or calamity, and that they were destroyed by the fire that consumed the Capitol in the Marsic war. After this calamity, ambassadors were sent to collect such fragments of Sibylline prophecies as they could pick up in various countries; and from the verses thus collected Augustus formed two new books, which were deposited in two gilt cases in the temple of the Palatine Apollo. Sibylline verses are often quoted by Christian writers, as containing prophecies of Christianity; but these were composed during the second century of the Christian era.

Sicilian Earth. A name sometimes given to fossil bezoar, which appears to be of a similar character to Armenian Bole.

Sicilian Vespers. In Modern History, the name commonly given to the great massacre of the French in Sicily, in A.D. 1282. They were the soldiers and subjects of Charles of Anjou, who had made himself master of the island after the defeat and death of Conradin. The insurrection broke out on the evening of Easter Tuesday. Its consequence was the expulsion of Charles; and the islanders placed themselves under the protection of the king of Arragon.

Sick-bay. On Shipboard, a portion of the main-deck partitioned off for invalids. It is usually in the bow. The partitions are easily removed, and in time of action, in a man-of-war, the sick-bay is transferred to the cockpit.

Sida (Gr. σίδη). An extensive genus of *Malvaceæ*, many of the species of which are used medicinally. The root of *S. acuta* is esteemed by the Hindus as a valuable stomachic, and is administered in ague, dysentery,

and as a remedy for snake-bites, while the leaves are used as a poultice, as likewise are those of *S. retusa*, *S. stipulata*, and *S. mauritiana*. Others are used in cases of rheumatism, and as an application in cases of the stings of wasps and other insects. The wood of these trees is extremely light; that of *S. micrantha* is used to make rocket-sticks in Brazil, where large quantities are employed on fête-days at the doors of the churches. The Chinese cultivate *S. tiliæfolia* for the sake of the fibre of its bark, which they prefer to hemp.

Side Keelsons. In large ships, keelsons parallel to, and somewhat smaller than the principal keelson, and distant about six feet from it. They extend from fifteen to twenty-five feet fore and aft of the main-mast, and are bolted through to the outside planking. The object is to give additional support to the ship's frame in the part adjoining the principal mast, and consequently the point of greatest strain.

Side Lever. The part of a certain species of marine engine which communicates the motion from the side rods to the cross tail, and which answers to the working beam in land engines. [STEAM ENGINE.]

Side-saddle Flower. One of the names of the curious pitcher-bearing genus of plants, called *Sarracenia* by botanists.

Sidereal System. [STAR.]

Siderite (Gr. σίδηρος, *iron*). Sparry Iron-ore, or native carbonate of iron. The term Siderite has also been applied to a vitreous variety of Quartz of an indigo or Berlin blue colour, from Golling near Salzburg.

Siderocalcite (a word coined from the Gr. σίδηρος, and Lat. calx, *lime*). The name given by Kirwan to the *Brown Spar* of Werner.

Sideroschistolite (Gr. σίδηρος; σχιστός, *cleavable*; and λίθος, *stone*). A hydrated silicate of iron, found in small six-sided black prisms at Conghonas do Campo in Brazil.

Sideroscope (Gr. σίδηρος; σκοπέω, *I view*). An instrument for detecting minute degrees of magnetism in substances usually supposed to be non-magnetic—the name having reference to the hypothesis that the traces of magnetism so detected are due to the presence of atoms of iron. The apparatus proposed by Lebaillif, in which the object is accomplished by means of a very delicate combination of magnetic needles, is described by Pouillet, *Élémens de Physique*, and by Sir D. Brewster, 'Treatise on Magnetism' in the *Encyclopædia Britannica*.

Sideroxylon (Gr. σίδηρος, and ξύλον, *wood*). A genus of Sapotaceous trees, often of large size, distributed over both hemispheres, but rarely extending beyond the tropics. Its name is given in allusion to the very hard wood afforded by the various species. The woods of many widely different trees, however, are likewise called Ironwood, almost every country producing a hard wood to which that name is applied.

The fruits of *S. dulcificum* have, as the specific name denotes, an exceedingly sweet taste, and are one of the kinds known to the English residents in Western tropical Africa (where the plant is indigenous) by the name of Miraculous-berry, being eaten in order to counteract the acidity of any article of food or drink, their sweet flavour being retained by the palate for a considerable length of time. They are rather more than half the size of olives, and somewhat of the same shape. Among the natives they form an article of trade.

Siege (Fr. siége; Ital. seggia, Lat. sedes, *a seat*, from the setting down of an army before the beleaguered fortress). A Military term, denoting the carrying on of offensive works and operations in the attack of fortresses.

The nature of sieges has, at all times, depended upon the character of the defensive works, and the arms and projectiles in use. In the days of slings, bows, and simple walls, the attack was conducted under great disadvantages. The more concentrated the garrison, the more strength it possessed. The attack could be made only within a short distance of the walls, and always in a direction parallel to the front attacked. Escalade was the first means of attack attempted, and when it failed, wooden towers, higher than the walls, were brought against the latter; the battering ram and the mine were employed to effect a breach.

The adoption of gunpowder and cannon greatly simplified the attack, for the walls, which had hitherto sufficed for defence, were easily breached by the heavy projectiles hurled against them. It became necessary, therefore, to protect the walls, and devise new modes of defence. [FORTIFICATION.] These, again, demanded a new mode of attack, the besieger bringing an overpowering fire on such of the works of the fortress as could be seen, and under its cover advancing close to the fortress, where he raised high mounds of earth, on the top of which he placed batteries to sweep the interior of the defences. Under cover of this fire, he either assaulted the place or advanced to a nearer position from which the walls could be breached. The attack thus conducted was very tedious, owing to the enormous labour of raising the mounds of earth for the *cavalier batteries*.

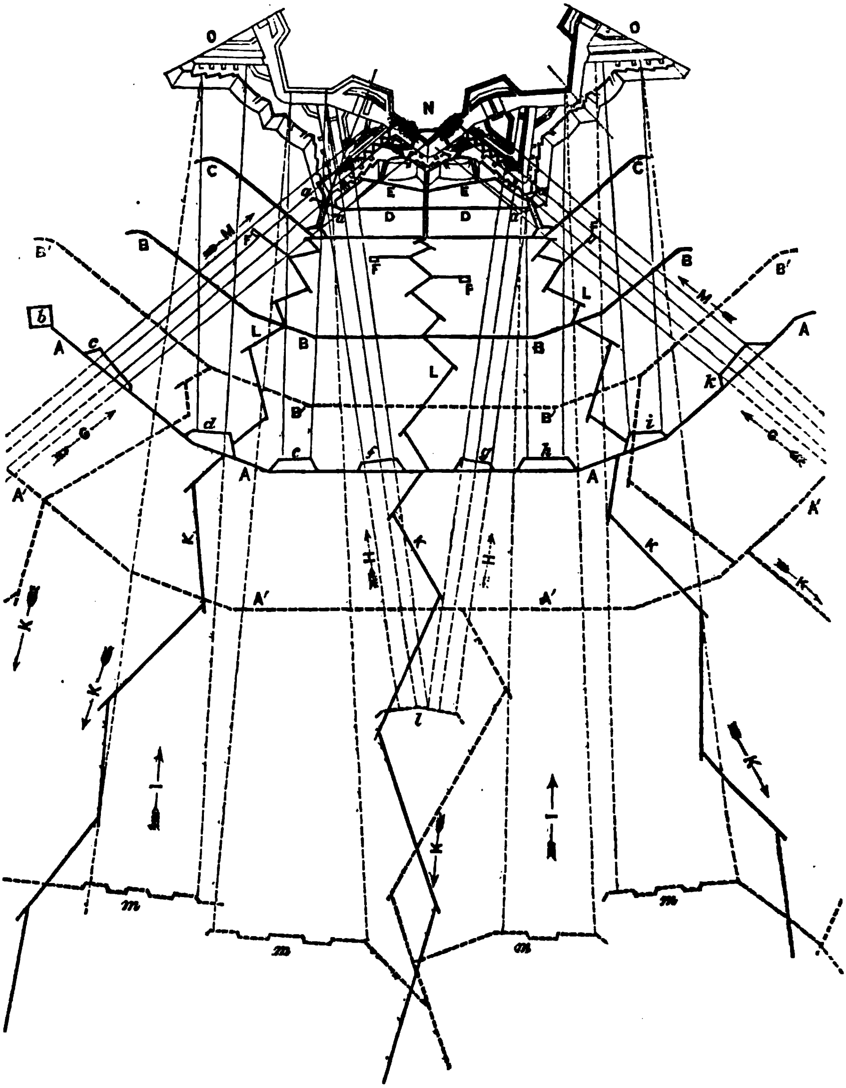
The genius of Vauban, however, by the invention of *ricochet fire*, and by modifying the ordinary siege works of the period, and combining them into a regular system of attack, shortened the duration of sieges, and gave them a certainty which they did not possess before.

The following sketch of a siege is based upon the practice of Vauban and other generals, and is supposed to be conducted against two ravelins and a bastion between them, of the modern French system, and with smooth-bore arms only, as no regular siege has been carried on since the introduction of rifled arms. The attacks on the small and feebly armed forts in America have been on too small a scale, and too irregular, to afford much information on regular sieges, and neither the Prussian nor Italian armies have undertaken the siege of

any Austrian fortress in the campaign of 1866.

The army advancing into the theatre of war for the reduction of a fortress, may be divided into two grand divisions, one for the actual siege, and the other called the *army of observation* or *covering army*, for operating in the field to prevent the interruption of the siege.

The besieging army may be subdivided into the investing corps and the attacking corps,



A' A' and A A. First parallels. A' A' extend to right and to left about 300 yards beyond margin. B B' and B B. Second parallels. C C. Third parallel. D D. Fourth parallel. E E. Fifth parallel. F F. Demi-parallels. G. Range 1,400 yards from batteries similar to *l*. H H. Range 1,400 yards. I I. Range 2,000 yards. K. Communications to Dépôts, Camps, &c. L L. Zigzags or approaches. M M. Range 600 yards. N. Attacked bastion with breaches. O. Similar works all round to complete Fortress. *a a.* Trench cavaliers. *b.* Redoubt. *c.* Enfilade battery, 12 guns. *d.* Counter battery, 12 guns. *e.* Counter battery, 14 guns. *f.* Enfilade battery, 7 guns. *g.* Enfilade battery, 7 guns. *h* Counter battery, 16 guns. *i.* Counter battery, 14 guns. *k.* Enfilade battery, 12 guns. *l.* Enfilade batteries. *m.* Small detached counter battery.

N.B.—The continued lines represent an attack with smooth-bored guns; the dotted lines an attack with rifled guns.

this latter furnishing the working parties and the guards of the trenches, to protect them from sorties. The investment [INVESTMENT OF A FORTRESS] is established suddenly and secretly, and is maintained rigorously throughout the whole siege, otherwise the fortress might be relieved, and the siege either prolonged or rendered hopeless. While the investment is being established, officers of the staff and engineers are employed in making and verifying plans of the fortress and adjacent ground, and in collecting every information bearing upon the proposed attack. This is called *making the reconnaissance*, and in doing so great care must be taken not to let the enemy know where it is proposed to attack the fortress, but, on the contrary, to endeavour to convey a false impression, this mistaken idea being often further carried out by the prosecution of a false attack for a considerable period.

The front most susceptible of attack having been selected, a project of attack is designed, which, however, can rarely be carried out in its integrity. The artillery park and the engineer dépôt are then placed conveniently, and out of sight and range of the fortress.

On the night in which ground is broken or the trenches opened, the *first parallel* or trench, to serve as a covered road and to protect the guards, is traced and constructed parallel to the works of the fortress, at a distance from them of from 400 to 800 yards, and extending on flank far enough to cover the most exposed batteries. During the same night trenches of communication are carried from the dépôts to the parallel, traced in *zigzags*, so that the enemy cannot see along their interior. All the parallels, communications, and approaches, are about three to four feet deep, and ten feet wide.

During the next few nights the batteries are constructed and armed, and in all possible cases enfilade batteries are employed to fire *en ricochet*. Three or four guns so placed, and sending their shot bounding along the face of the enemy's works, will dismount or disable all the guns on the face enfiladed. When it is impossible to have enfilade batteries, direct or counter batteries are constructed, replying with one or two guns to every gun mounted on the face to be silenced. When these batteries have in a great measure silenced the artillery fire of the fortress, a *second parallel* is constructed about half-way between the first parallel and the fortress, and communications made between the parallels by zigzags.

When the artillery fire of the place has been completely silenced, the approaches are pushed on by sapping, a very slow process, the advance depending on the rate at which the sapper, at the head of the sap, can work, rolling on before him the covering sap roller, and placing the gabions to be filled with earth. When the heads of these approaches are too far advanced from the parallel for proper support, short trenches called *demi-parallels* are pushed out right and left, and guards of the trenches placed in them. The approaches are again pushed on to within about 120 yards of the covered way, where the *third parallel* is constructed, connecting the heads of the attacks. The next object to be attained is the *crowning of the covered way* of the ravelins; i.e. the formation of a trench or lodgment along the edge of the glacis, that position being reached either by systematic approach, or by the hazardous operation of assault, in which a storming party drives the defenders out of the covered way, a working party following with the necessary tools and materials to form the lodgment outside the covered way.

In the advance by systematic approach, saps are driven direct upon the salients of the covered way to about forty yards from the salients, where raised musketry parapets or *trench cavaliers* are constructed to enfilade the covered way. A *fourth parallel* connects the two inner cavaliers. The saps are again pushed on to within twenty feet of the salients, where they branch out right and left, forming the lodgment on the glacis or crowning of the covered way. A *fifth parallel* connects the inner ends of these lodgments. Batteries are then formed in these lodgments to breach the ravelins and silence the flanking fire of their ditches. A *great gallery of descent*, for the passage of the storming parties, is driven underground from the lodgment into the ditch (opposite the breach) across which a sap is driven; the breach is captured and crowned with a lodgment; and saps made across the salient of the ravelin, from which guns and muskets keep down the fire of the place.

The redoubt of the ravelin is breached by mines, and when this work falls the covered way in front of the bastion may be crowned, without fear of these lodgments being seen into from the redoubt. Batteries are formed in these lodgments to oppose the flanking fire of the main ditch to be crossed. Saps are pushed on in the redoubts of the ravelins until the *coupures* of the ravelins are taken in reverse, when, the enemy abandoning them, they are taken possession of, and from them the redoubts in the covered way are taken in reverse, and these being abandoned are occupied and furnish sites for the principal breaching batteries, others being likewise constructed outside the redoubts. While these batteries are breaching the main escarp, saps are driven to the edge of the main ditch, the walls of which are mined, access being thus given to the main ditch, across which saps are driven to the breaches, which on being captured are crowned, and thus the salient of the bastion is taken possession of. The place may then be said to have fallen; for if the besieged have constructed any retrenchments inside, they will soon be reduced by similar operations or by assault.

These works, if carried on without interruption, would occupy about forty nights.

As to the future of sieges, the balance of professional opinion is decidedly in favour of the defence, under the assumptions that iron in the form of cupolas, shields, and plates is available, as well as large rifled guns carrying elongated

shells with large bursting charges. There can be no doubt but that great delay will be caused, for the siege works must be commenced much farther off, and the besiegers' first batteries will be repeatedly blown to pieces with large shells during their attempted construction.

If the fortress can preserve a few guns in cupolas or behind shields, it will be impossible to sap, at least by day, unless the sap be made nearly twice as deep as heretofore, adding thereby immensely to the labour and causing delays.

Mining may be resorted to, but even with the aid of machinery it must always be a slow and precarious method.

The circumstances under which a strong fortress, amply provided for defence, could be successfully besieged, would appear to be:—

1. Extensive and uninterrupted railway or maritime communication.

2. A lavish supply of large rifled ordnance.

3. An army large enough to supply the extensive working parties which in future will be necessary.

As to the attack of fortresses of the polygonal or German system, it would appear that their reduction will present greater difficulties and delays than in the other systems, for they will offer none of their principal faces for enfilade; they will bring a more powerful fire on the field of attack, which fire must be met with counter batteries, and the well-preserved powerful flanking fire for the main ditch will be very difficult to subdue at the critical part of the attack.

One grand feature of future sieges will undoubtedly be the placing of guns in a large number of small batteries, instead of crowding the guns into a few large batteries. The advantage also which the cover of night afforded to the attacker will in a great measure be neutralised by means of the powerful light which modern science will throw on the field of attack, to disclose the besiegers' operations.

Finally, if it be conceded that sieges, in future, must be of considerably longer duration than formerly, it would follow that many fortresses, although not absolutely impregnable, will virtually become so, from the impossibility of devoting the necessary time to their reduction in ordinary campaigns.

Siege Train. The combination of artillery, both men and material, formed for the conduct of a siege.

Siegenite. A name for Cobalt Pyrites, after Siegen, one of its localities. [LINNÆITE.]

Sienna and Raw Sienna Earth. [TERRA DI SIENNA.]

Sierra (Lat. serra, *a saw*). A Spanish term, signifying a chain of hills, and prefixed to the names of several places in Spain, and other parts discovered or colonised by the Spaniards.

Siesta (Span.). The name given to the practice indulged in by the Spaniards, and the inhabitants of hot climates generally, of resting two or three hours in the middle of the day, when the heat is too oppressive to admit of their going from home.

Sifrit. In Mythology. [SIGURDR.]

Sigaultian Operation. The division of the *symphysis pubis*, for the purpose of increasing the capacity of the pelvis in cases of impracticable labour. It was first performed by a French surgeon of the name of Sigault, but is now discarded.

Sight. [VISION.]

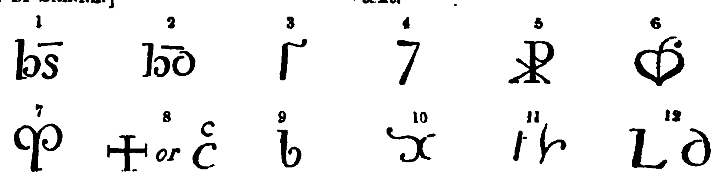
Sights for Ordnance. Pieces of wood or metal attached to a gun, in order to *lay* the gun accurately, by bringing them in line with the object aimed at. The hind sight is always capable of being raised so as to vary the angle of elevation of the gun to the exact extent required. [GUNNERY.] Smooth-bored land-service cast-iron guns are provided with *Millar's sights*, consisting of a graduated tangent scale at the breech, and a dispart sight in front of the second reinforce. A wooden tangent scale is also supplied, and used for elevations over the *clearance angle*.

The rifled guns in our service are provided with a *barrel-headed tangent sight* and a *trunnion sight* on each side of the gun. The *barrel-headed sight*, instead of rising in a vertical plane, as with a smooth-bored gun, rises at an angle to the left from the vertical, in order to allow for the *derivation* of the shot. [PROJECTILE.] The larger rifled guns have also centre-sights.

The radii to which the metal tangent scales are graduated are the distances from their heads to the dispart or trunnion sight, but the wooden tangent scales are graduated to the long radius, or the notch on the muzzle.

Sigillaria (Lat.). Fossil plants found in the coal formation. They are represented mainly by the stems, which have leaf-scars, like seal-impressions: whence the name of the genus.

Sigla. In Printing and in ancient MSS., notes, breviatures, letters used for words, characters or shorthand. Some specimens of the sigla of the sixth, seventh, and eighth centuries are here given. Some of them were invented by the writers themselves, or afterwards by others in illustration of the text.



1. H.S. i.e. Hic suppleas, or hæc supplenda.
2. H.D. i. e. Hoc deficit, or hæc deficiunt.
3. Paragraphus, a note of division.
4. Diple, to mark out a quotation from the Old Testament.
5. Crisimon, being composed of X and P, which stands for Christ. [LABARUM.]
6. Hederacei folii figura, an ivy leaf, the ancient mark of division.
7. Ancora superior. To denote a very remarkable passage.
8. Denotes the beginning of a lesson.
9. Signifies good.
10. Stands for something very kind, or benevolent.
11. Points out a fine or admirable passage.
12. L.D. *lepide dictum*. Finely said.

(See Octavius de Strada, Negitius, Frontinus, and Johannes Nicholaus.)

Sign (Lat. signum). In Algebra, a symbol indicating an operation to be performed, or a relation subsisting between two quantities. Of the former kind, those most commonly used are, + for addition, − for subtraction, × for multiplication, ÷ for division, $\sqrt{}$ for the square root, $\sqrt[3]{}$ for the cube root, $\sqrt[n]{}$ for the nth root, &c. The signs denoting relations are, = equal to, > greater than, < less than, &c.

SIGN. In Astronomy, a portion of the ecliptic or zodiac, containing thirty degrees, or a twelfth part of the complete circle. The first commences at the point of the equator through which the sun passes at the time of the vernal equinox; and they are counted onwards, proceeding from west to east, according to the annual course of the sun, all round the circle. The names of the twelve signs, in the order in which they follow each other, with the characters by which they are indicated on globes, and in the almanacks and books of astronomy, are as follows: *Aries* ♈, *Taurus* ♉, *Gemini* ♊, *Cancer* ♋, *Leo* ♌, *Virgo* ♍, *Libra* ♎, *Scorpio* ♏, *Sagittarius* ♐, *Capricornus* ♑, *Aquarius* ♒, *Pisces* ♓.

It is to be remarked, that the above are also the names of the twelve constellations of the zodiac; and in ancient times (above 200 years before our era), the places of the signs and the constellations were coincident; but owing to the motion of the earth's equator, by which the equinoctial points are carried backwards on the ecliptic about 50·6″ annually, the intersections of the ecliptic and equator, and consequently the commencement of the signs, now correspond to different stars, the first point of the sign Aries being at present near the beginning of the constellation Pisces. On this account care must be taken not to confound the signs of the zodiac, which are fixed in respect of the equinoxes, with the constellations, which are movable in respect of those points. [CONSTELLATION.]

The *ascending signs* are the six beginning with Capricornus, through which the sun passes while advancing from the winter to the summer solstice, and is, consequently, acquiring altitude with respect to inhabitants of the northern hemisphere. The other six, beginning with Cancer, are called the *descending signs*.

SIGN. A picture hung in front of inns; a remnant of a custom which formerly prevailed with regard to shops in general.

Sign, Botanical. [SYMBOLS, BOTANICAL.]

Sign Manual. The royal signature, superscribed at the top of bills of grants or letters patent; which are then sealed with the privy signet or great seal, as the case may be, to complete their validity. But there are some grants which pass through certain offices, as the Admiralty or Treasury, under the sign manual only.

Signal Light. [BLUE LIGHT.]

Signals. [TELEGRAPH.]

Signals, Naval. A system of symbols addressed to the eye—as flags, boards, lights, &c.—for establishing communications at distances too great for the voice. Guns are also used for the same purposes. The first signals seem to have been merely distinguishing flags for certain ships. In the system instituted by James II. for orders to the fleet, the purport depended on the part of the ship at which they were exhibited; a condition very detrimental to the use of signals at sea. A code composed of *numeral* flags and pendants, i.e. in which each combination of numbers had a verbal expression assigned to it, seems to have been the first step towards a general system, as before this plan each admiral instituted his own code. In 1815, Sir Home Popham's code was adopted. This added several *literal* or alphabetical flags and pendants, which greatly extended the means of communication, but necessarily rendered the signals indistinct, and their purports deceitful, in many cases, from the increased difficulty of distinguishing each flag from the rest. In 1826, in consequence of some plans having been submitted by admirals for a more efficient system, the code still partly in use, which was considered as an improvement on its predecessor, was adopted. In 1828, Admiral Raper published his code, which was one of those under consideration. The principle of this system was that the manner of combination of the flags and pendants of which the signal is composed, i.e. their order or arrangement, should point out the subject of the signal, or, as the author terms it, the *point of service* to which the signal relates; while the *numbers* of the individual symbols indicate the number of the signal in its class. The numbers are denoted, as usual, by the colours; but when these fail, from haze or distance, the number is supplied by *numeral distant signals*. From the distinctness attending the small number of symbols (the smallest possible for complete numeral signals), the precision obtained from classification by which the simplicity of each signal is proportioned to its importance, and the saving of the time often wasted in vain attempts to distinguish the precise disposition of the colours

of each flag, this system has been considered by some competent judges as the sole thoroughly efficient method.

In the merchant service, signals are of less extensive utility than in the royal navy, their chief employment being to express the names of vessels, latitude and longitude, and a few other such particulars. Attempts have been made by the principal maritime governments to establish a universal code of signals for the mercantile marine of all nations.

The colours of flags are rather a drawback to their usefulness, as at a distance signalmen find it hard to distinguish between blue, red, and black, or between yellow and white. Some modern systems have therefore been tried with only black and white in the flags. This, of course, diminishes the number of symbols. But flags, generally, are subject to the objection of indistinctness. On a still day they will not extend at all; on a windy day they may happen to extend in a direction end on to the observer, when of necessity they will be unintelligible. Solid figures, of canvas on iron frames, have been tried; but the cone, sphere, cylinder, and cube, are the only figures which presented the same appearance in every direction. The reduction in the number of symbols renders a *code* desirable. With many flags hung one above another it is easy to spell a word, and this is known as *word signalling*, but with few symbols—the nine numerals, 0, and two repeaters for instance—it saves much time if a combination of four symbols be taken arbitrarily to represent a word or common sentence. This is a code. The symbols named above are sufficient to communicate 14,000 words and phrases; and they constitute the basis of the code adopted by the Admiralty and the Board of Trade. In addition to other advantages over word-signalling, the code has the gain of being applicable to any signals—flag, telegraph, flashes, &c.—and the numbers, representing not spelling of words but the idea embodied in those words, are equally applicable in all languages. The next competition is between signalling and telegraphing; in the former the whole word or combination of numerals is exposed at once, while, in the second, one letter or numeral is shown at one motion. At first sight the former seems the quicker mode; but the preparatory arrangements take longer, more apparatus is requisite (at least twelve different signs being indispensable) than with the telegraph, where four signs, each of which can be shown affirmatively or negatively, answer all the purposes. The simplicity of the telegraph system will certainly make it general before long.

Having shown that word-signals must yield to codes, and that codes can be better communicated by telegraphing than signalling, it is only necessary to show the various apparatus used for the latter. The oldest of the modern telegraphs is the *arm* telegraph, still used on railways; here a post with two revolving arms can make any signal. It is, however, only visible at a point in front or nearly in front. The great improvement was Redl's cones, consisting of four black cones on a mast. Each cone is constructed like an umbrella, and, by means of a spring, its normal position is closed tight upon the mast. By a cord from each cone, the operator can open it at will, and keep it in an open position as he pleases. The cones represent four positions—open, positive; shut, negative. By combinations of these, all the symbols for telegraphing are obtained. The signs can be changed with the utmost rapidity; the mast is light, and easily removed from one point to another; it forms a ready communication from ship to shore, between portions of armies, or indeed in any situation, as the signals appear the same in every direction. For day telegraphing these cones have now been universally adopted in the British service. Several ingenious officers—and notably Captains Bolton and Colomb—have developed the system of the cones to any signs whatever which admit of four positions and a positive or negative aspect. Thus, two men's arms extended or by their sides; one man raising an arm, with or without a handkerchief, four times in quick succession; four notes on a horn or steam-whistle—long notes for positive, short notes for negative—constitute a telegraph ready for use. Many experiments have been made to try the most efficient symbols for distant telegraphy. The results have given the preference for day signalling to jets of steam, long or short, and for night purposes to the flashes of a strong light. For this latter purpose the light is covered by a shade and exposed $1\frac{1}{2}$ seconds for a positive signal and half a second for negatives. Four puffs of steam or flashes of light constitute a symbol, and four symbols one phrase or word, as shown by the code. It is needless to point out that these time-signals are precisely on the principle of Morse's electric telegraph.

'Steam-jet,' 'Flashing,' 'Sound,' or 'Electric Telegraph Time-signals,' representing the symbol 3,591, to which an arbitrary meaning is attached.

Signature (Lat. signatura). In Music, the flats and sharps placed after the clef, at the beginning of the staff, which affect, throughout the movement, all notes of the same letter.

SIGNATURE. In Printing, a letter of the alphabet placed at the bottom of the first page of each sheet of a work, to denote, alphabetically, the order of the sheets.

It is customary to commence with B on the first sheet of the body of the work, and to go regularly through the alphabet, with the exception of the letters J, V, and W, which are never used as signatures, and which had,

in fact, no existence in the alphabet at the time of the invention of printing; 𝕴 expressing both I and J; 𝖀, both U and V; and 𝖂, the double letter W. If the work extend to more sheets in number than there are letters in the alphabet, the succeeding sheets go on with a second alphabet, which commences with A, and both the letters are usually given; in this manner, A A, or A a, and sometimes, to avoid the repetition, thus, 2 A. If a third alphabet be necessary, it is always, at the present day, placed with the number before it, as 3 A. The printer's first alphabet consists of twenty-two letters, and the second and succeeding ones of twenty-three.

As a guide to the bookbinder, there are other signatures used in a sheet besides the first. In a sheet of octavo it was till recently usual for the first page to have B, the third B 2, the fifth B 3, and the seventh B 4: in a sheet of twelves they were carried to B 6, B 5 being the first page of the offcut; and however numerous the pages may be in a sheet with one signature, when they were all inserted, they were continued to the last odd page before the middle of the sheet, but never carried beyond the middle. In general they were all omitted except the first two, to show the first fold of the paper, and the first on the offcut. Small capitals are more frequently used for signatures than large capitals, as disfiguring the foot of the page in a slighter manner. Sometimes figures are used instead of letters, but not often; the *Gentleman's Magazine* is an instance.

Signatures, Doctrine of. A belief held by some ancient physicians and pharmaceutists that every natural substance which possesses medicinal virtue, indicates, by an obvious external character, the disease for which it is a remedy, or the object for which it should be employed. Hence, it was assumed that poppies must relieve diseases of the head, from the form of their seed-vessels; turmeric, being yellow, must cure jaundice; *cassia fistula*, intestinal disorders; groomwell (or lithospermum), gravelly disorders, from the polish and hardness of its seeds; and so on. Upon this principle it is probable that red cloth was held in estimation as an application to cutaneous eruptions, and that John of Gaddesden in the fourteenth century ordered the son of Edward I., who was attacked with smallpox, to be wrapped in scarlet cloth and lie in a room with scarlet hangings.

Signet, The Privy. One of the royal seals in England, used in sealing private letters and grants under the sign manual. It is in the custody of the Secretary of State for the Home Department. [Seal; Secretary.] The signet in Scotland is the seal by which the royal letters and writs for the purpose of justice are now authenticated. Hence, the title of clerks to the signet, or writers to the signet; whose business is nearly the same with that of attorneys in England. They were anciently clerks in the office of the Secretary of State, by whom writs were prepared; and when the signet became employed in judicial proceedings, they obtained a monopoly of the privileges of acting as agents or attorneys before the Court of Session.

Significant Digits of a Number. Those digits which remain after striking off all the ciphers on the right or left. Thus the signifi-

cant digits of 12300 are 1, 2, 3, and those of the decimal number ·00301 are 301. It is in logarithms that this distinction is usefully made. The logarithms of all numbers whose significant digits are the same have the same *mantissa* or decimal part, and differ only in their *characteristics*. The number of places, to the left or right of the unit's place, of the first (extreme left) significant digit gives, respectively, the positive or negative characteristic of the logarithm. [LOGARITHMS.]

Signor (Span. señor; Lat. senior, *elder*). The Italian term equivalent to the English *Lord*, *Sir*, or *Mr.*, the French *Monsieur*, and the German *Herr*. *Signoria* was anciently the appellation of the chief council of Venice, Genoa, and Lucca.

Sigurdr. In Northern Mythology, the great hero of the VOLSUNGA SAGA, which was afterwards expanded in the EDDA and finally remodelled in the lay of the NIBELUNGEN.

Sigurdr, in the tale of the Volsungs, is the son of Sigmund, born after his father's death. Sigmund, the son of Volsung, a descendant of ODIN, had gained possession of the sword Gram, which Odin in disguise had driven to the hilt in an oak trunk, and left for the man who was strong enough to draw it out. With this sword Sigmund overcomes every enemy, until, in a battle between him and the sons of King Hunding, Odin reappears in his old disguise and presents a spear on which the sword Gram is broken in twain. Sigmund then dies on the battle-field, and his wife Hjordis gives birth to Sigurdr, in the house of Hialprek, king of Denmark. This child, the favourite hero of Teutonic song, grows up into a manhood as majestic as that of PHŒBUS and Achilleus. [ILIAD.] His golden locks flow down over his shoulders, and gleam like the rays of the sun; his eye is bright and piercing, and his countenance full of splendour. He is the foster child of Regin (the smith of King Hialprek), who urges him on to slay the dragon Fafnir [PYTHON], who lay on the glistening heath, coiled round a heap of gold. But Sigurdr, bent first on avenging his father's death, asks Regin to forge him a new sword. The weapon snaps in his hand; and Sigurdr then obtains from his mother the broken bits of Gram, out of which Regin forges a new blade, the force of which nothing could withstand. Having slain the sons of King Hunding, Sigurdr attacks and slays Fafnir, thus becoming master of the golden treasure, and with it of a ring on which Andvari the dwarf had laid a curse, by which it should become the bane of every man who owned it. By eating Fafnir's heart, Sigurdr is also endowed with a marvellous wisdom, which enables him to understand the song of birds. Riding away with his spoil, he came to a lonely heath, in the midst of which a fierce flame surrounded a house, in which lay a fair maiden Brenhyldr, the daughter of Atli, in a sleep never to be broken until there came some one brave enough to ride through the flame. At the touch of Sigurdr, she wakes up, and Sigurdr, having plighted to her his troth, rides on to the house of Giuki the Niflung [NEPHELÊ], who determines that Sigurdr shall marry his daughter Gudrun. So Grimhildr, Giuki's wife, gave him a potion which caused him to forget Brenhyldr, and Gudrun becomes the wife of Sigurdr.

Meanwhile, Brenhyldr still waited the return of Sigurdr to rescue her from her captivity. Gunnar, the brother of Gudrun, having resolved to marry Brenhyldr, tries in vain to ride through the fire, and therefore Grimhildr by her magic arts made Sigurdr change shapes and arms with Gunnar, and so deliver Brenhyldr. On the bridal bed Sigurdr places his sword Gram between himself and Brenhyldr, to whom in the morning he gives the ring of Andvari, receiving from her another in return. Sigurdr then resuming his shape, hands Brenhyldr over to Gunnar; but no sooner has he done this than the power of the magic potion passes away, and he sees too late that he has betrayed his first love. At length, from Gudrun, Brenhyldr learns that she was rescued from the flame not by Gunnar, as she thought, but by Sigurdr; and, her love for the hero giving place to indignation at his treachery, she urges on Gunnar and his brothers to slay him. But they had sworn, as the gods had sworn in the case of Baldr, not to hurt Sigurdr. Hence, that which they would not do themselves, they incite their half-brother Guttorm to do for them. Thus was Sigurdr slain as he lay sleeping; but his death revives all the love of Brenhyldr, and lying down by the side of Sigurdr, with his good sword Gram between them, she dies heart-broken on his funeral pile. Then Gudrun, wandering away, becomes the wife of Atli (the brother of Brenhyldr), who claims the treasures won by Sigurdr from the dragon, but which the Niflungs had taken when Sigurdr was slain. Unable to gain them by force, Atli invites Gunnar and his brethren to a feast, and then ensnares them. Gunnar is thrown into a pit of serpents, one of which flies at his heart and stings him to death. Gudrun then, in revenge for the death of her brothers, first slays her children by Atli, and then kills her husband Atli himself. Weary of her life, she casts herself into the sea; but the sea will not let her die, and bears her to the land of king Jonakr, by whom she becomes the mother of three sons, who are all dark haired like the Niflungs, and a daughter, Swanhild, whom Hermanric seeks for his wife, sending his son Randver to woo her. Randver, instead of doing his father's bidding, seeks her for himself, and for this misdeed is put to death. Afterwards, seeing Swanhild washing her golden hair, Hermanric rides his horse over her, as the cause of all his troubles, and tramples her to death. Gudrun then bids her sons avenge their sister, and they slay Hermanric in his sleep, as Sigurdr had been slain by Guttorm. For this crime they are put to death; and, soon after, the weary life of Gudrun comes to an end.

This Teutonic myth has a double value, (1) as

throwing light on the mythology of other races, and (2) as enabling us to form a judgment on the quasi-historical character which some myths have assumed.

(1) It will probably be disputed by none, that if in two tales full of startling events two or three incidents should be found common to both, a certain connection may be inferred between the stories; and it may be assumed either that they are the work of the same writer, or if of two writers, that one borrowed from the other, or that both obtained their materials from one common source. If the number of these common incidents be multiplied, the presumption of a connection between the stories is indefinitely strengthened; and in proportion to the improbability that one writer borrowed from the other, the conclusion that they worked on a common stock of materials gathers force. But, if it be found that these common incidents have the same sequence, that the motives assigned to the actors in these tales, as well as their characteristic features, are in each case the same, it seems impossible to doubt that the tales have a common substratum; and as the idea that the authors of the Volsung tale borrowed their materials from the *Iliad* or the *Odyssey*, or that the Greek epic poets borrowed from those of Persia and India, is too wild to be entertained by any who have studied the conditions under which traditions are diffused, it follows that legends exhibiting the same features in common point to one and the same source, from which the tales have been carried in different directions, to receive in their distant homes a new local colouring, with modifications which must be the result of new geographical features and new conditions of soil and climate.

Some points of resemblance between the myth of Sigurdr with the myths of non-Teutonic peoples have been already pointed out. But the correspondence may be traced in almost every detail. If Odin leaves a sword which is to become the property of him who is able to draw it from the oak trunk, so Ægeus hides his weapons beneath a stone, which must be lifted by THESEUS before he can become possessed of his father's arms. The portrait of Sigurdr is also the portrait of Phœbus Apollo, of Achilleus and ODYSSEUS, of PHAETHON, Patroclus, and TELEMACHUS. From Hjordis, his mother, Sigurdr obtains the sword Gram, reforged by Regin the blacksmith, brother of the Danish king; from Thetis, Achilleus receives the armour which the smith HEPHÆSTUS had made, in place of that which Hector had stripped from the body of Patroclus. The vengeance taken by Sigurdr on the sons of king Hunding is the revenge taken by Achilleus on the Trojans for the death of his friend. His slaughter of Fafnir is the slaughter of Python by Phœbus, of the Minotaur by THESEUS, of the Libyan dragon by PERSEUS, of the Sphinx by Œdipus, of the snakes which HERACLES strangles at the outset of his career. The power granted to Sigurdr of understanding the voices of birds is granted also to Iamos, and Melampus is taught the same wisdom by serpents. If Brenhyldr sinks into a death-like sleep, after being wounded with a thorn by Odin, so is Isfendiyar, in the Persian epic, slain with a thorn by Rustem. Brenhyldr the maiden is PERSEPHONE, the Korê or Girl; like Persephonê, she is taken away from the world of the bright gods, and guarded in a dismal land, from which one hero alone can deliver her, as Andromeda can be rescued from the dragon only by the invincible Perseus. Brenhyldr, again, is the first love of Sigurdr; to her he plights his faith in the spring time of his life, and scarcely have they met before they must part. So was it with Iolê and Heracles, with Œnônê and PARIS, with Odysseus and Penelopê, with Brisêis and Achilleus. In these legends the relation of Gudrun to Brenhyldr is that of Deianeira to Heracles, of Helen to Paris once called Alexandros; and in each case the desertion is followed by vengeance. The 'wrongs and woes' of Helen roused the wrath of the Achæan chieftains; and the death of Paris answers to that of Sigurdr. In each case the deserted maiden reappears, forgiving and tender at the close. Œnônê cannot heal Paris, but like Brenhyldr she lies down on the fiery couch by his side; and Iolê stands by the funeral pile of Heracles on the rugged heights of Œta.

The remainder of the tale only repeats the story of Sigurdr in a modified form; and the same substantial repetition is seen in the tale of Ragnar Lodbrog, Aslauga, and Thora. In the traditional history, this Lodbrog, or Lothebrok, is said to have been murdered by Biorn, the huntsman of Edmund, king of the East Angles. With the historical character of this statement we are not here concerned; but it is significant that Ragnar wins his first wife Thora by delivering her from a dragon as Sigurdr rescued Brenhyldr. Ragnar Lodbrog is, again, a son of Sigurdr. After Thora's death, he woos Kraka, whom he is on the point of deserting for the daughter of Osten, when Kraka reveals herself as the child of Sigurdr and Brenhyldr (Thorpe's *Northern Mythology*, i. 108, 113); and thus the tale of Sigurdr and Brenhyldr is reproduced in that of Randver and Swanhild, as well as in that of Ragnar and Aslauga.

If a comparison of Teutonic with Greek and Aryan mythology supplies the key which unlocks the secret of this astonishing parallelism, the discovery may be welcomed as setting at rest many very perplexing questions and some disagreeable doubts. But the parallelism would nevertheless remain a fact, even if we were altogether unable to explain it. For the light thrown on the subject by comparative mythologists, the reader is referred to the articles MYTHOLOGY; LANGUAGE; POLYONYMY; SYNONYMY. It may suffice here to remark that Sigurdr, in his brilliant life and early death, in his desertion of his firstborn, in his physical features, in his matchless bravery and his invincible weapons, in the struggle which follows his marriage with Gudrun, and in the forgiveness of Brenhyldr when his offence has been atoned by his death, reproduces with singular

exactness the chief features in the myths of Apollo, Heracles, Meleagros, Bellerophon, Achilleus, Odysseus, Paris, Perseus, Theseus, Rustem, Kephalos, and other heroes. And, finally, it may be noted that the myth of the marriage of Gudrun with Atli exhibits in her jealousy and the slaughter of her children the closest parallelism to the myth of MEDEIA and Jason.

2. But the myth of Sigurdr, in its later developements, is (if possible) even more important, as showing the slender value which can be assigned to a legend, on the ground that it mentions names which we may know to be historical. Charlemagne is as much an historical personage as William III. or Sir Isaac Newton; and it may be asserted, that the myths which have gathered round his name preserve, amid many perversions, a certain groundwork of real history. But without the testimony of witnesses known to be contemporary, we could not distinguish between that which is and that which is not historical. Speaking of a battle fought against the Basques, Eginhard mentions among the slain, 'Hruodlandus Britannici limitis præfectus.' This is, probably, the Roland of chivalrous mythology, who fell at Roncesvalles. Knowing, thus, from other sources, that Charlemagne had an officer named Hruodland or Roland, we are, perhaps, able to say that the tales relating to Roland have gathered round a person of whom we know the name, but nothing more. But as soon as we leave the sure ground of historical testimony, the test is found to be delusive. The story of the Nibelungen Lay is essentially the same as that of the Volsung tale; but the names, still preserving a resemblance to those in the earlier saga, are in the later poem the names of persons whom we know to be historical. Thus, Gunnar becomes Gunther, a Burgundian king of the fifth century, who was conquered by the Huns of Attila. Hence, Atli, the brother of Brenhyldr, and the second husband of Gudrun, is changed into Attila; while Sigurdr has been identified with Siegbert, king of Austrasia, 'who was actually married to the famous Brunehault, who actually defeated the Huns, and was actually murdered by Fredegond, the mistress of his brother Chilperic.' 'This coincidence between myth and history,' remarks Professor Max Müller, 'is so great, that it has induced some euhemeristic critics to derive the whole legend of the Nibelung from Austrasian history, and to make the murder of Siegbert by Brunehault the basis of the murder of Sifrit or Sigurdr by Brenhyldr. Fortunately, it is easier to answer these German than the old Greek euhemerists, for we find, in contemporary history, that Jornandes, who wrote his history at least twenty years before the death of the Austrasian Siegbert, knew already the daughter of the mythic Sigurdr, Swanhild, who was born, according to the Edda, after the murder of her father, and afterwards killed by Jörmunrekr [Hermanric], whom the poem has again historicised in Hermanicus, a Gothic king of the fourth century.' (*Comparative Mythology*, 68.)

Now, here we have to note that we know the names of Gundicar, Siegbert, Dietrich of Bern, (=Theodoric who lived at Verona), Brunehault, Hermanicus, and others mentioned in the lay, to be the names of historical persons, only because we find them in authentic contemporary narratives; but from the *Nibelungen Lied* we do not learn even their names. If we had not obtained the knowledge from other sources, we could not have known from the poem that Siegbert ever lived, and could no more have been justified in saying that he was murdered, than we are now justified in saying that the coast of Kent witnessed the landing of Brute, the Trojan, on the shores of England. Hence, so far as the lay is concerned, Attila, Brunehault, and all the rest are mere names; while of the men themselves we know absolutely nothing.

If we apply this canon to the epics of the Homeric age, we find ourselves confronted with names of places, some of which tell their own tale as belonging to the regions of cloud and mist, while others are indubitably names of places known to us in history. But beyond this they make certain statements about places, which manifestly hold good at the present day. Tiryns and Mykênæ still exist, and their huge walls attest the past greatness of their rulers. When, therefore, the poems speak of these places as powerful cities, they state what is historically true; but we learn the fact not from the poems, but from the actual remains of these towns, whose greatness precedes the dawn of contemporary history. Hence, when the poet tells us that the name of the prince who ruled at Mykênæ was Agamemnon, he may be stating what is not less historically true than his statement that Tiryns had great walls; but so far as the *Iliad* is concerned, Agamemnon remains to us a mere name, while of the events of his life, or of the fortunes of his companions, we know absolutely nothing. They may have fought at Troy; but as we cannot deny the possibility of this fact, so neither can we affirm its reality. That some powerful chiefs must have ruled in Mykênæ, we know; that the name of one of these chiefs was Agamemnon, we can neither maintain nor deny; that he may have done some of the things attributed to him is at once within the limits of possibility and beyond the limits of human knowledge, in the absence of contemporary historical testimony. But it is quite certain that much of what is told of him and his allies could never have taken place; and a comparison of Greek and Hindu myths seems to force on us the conclusion that many, if not most, of the names of the Achæan chieftains are derived from a source common to the Homeric poems and the Vedic hymns. The coincidence of Argynnis and Arjunî, of Brisêis and Vrisaya, of Paris and Pani, of Helen and Saramâ, of Ixion and Akshivan, of Achilleus and Ahalya,

of Daphne and Dahanâ, of Phoroneus and Bhuranyu, with many others, cannot possibly be the result of accident, or of conscious borrowing on the part of the Homeric poets from poets who dwelt between the Ganges and the Indus.

The conclusion is, that we are not justified in denying that men and women, bearing the names which occur in the Homeric or other poems, may have lived in the places to which they are assigned, and may have done some of the acts ascribed to them, and at the same time that we have no warrant (in the absence of historical testimony) for maintaining that they did so act, or that they ever lived at all.

Silenaceæ. One of the names proposed for the *Caryophyllaceæ*.

Silentiary (Lat. silentiarius, from silentium, *silence*). Among the Romans, the title of office of a class of slaves attached to wealthy houses. In the court of the emperors, there was a body of officers attached to the household styled *silentiaries*. Thence the title came to functionaries of higher authority, and was borne by cabinet secretaries in the so-called Lower Empire, and in the courts of Charlemagne and other western potentates who derived their code of ceremonial from Byzantium. Members of the privy council seem to have been sometimes called by this name under the Plantagenets in England.

Silenus (Gr. Σιληνός). In Greek Mythology, the foster-father and attendant of Bacchus, and likewise leader of the satyrs. He was represented as a robust old man in a state of intoxication, and riding on an ass, with a can in his hand. He was invested with prophetic powers, and hence became the symbol of wisdom hidden beneath a rough exterior.

Silex (Lat.) or **Silica.** This important substance constitutes the characteristic ingredient of a great variety of silicious minerals; among which rock-crystal, quartz, chalcedony, and flint may be considered as silica nearly pure. It also predominates in many of the rocky masses which constitute the crust of our globe, such as granite, the varieties of sandstone, and quartz rock. Although silica has none of the ordinary or more obvious acid properties, yet, as it combines in definite proportion with many salifiable bases, and expels carbonic acid when fused with the carbonated alkalies, it is termed *silicic acid*, and its various compounds have been denominated *silicates*. When pure and colourless rock-crystal is heated red hot, and quenched in water, it becomes opaque and friable; and if in this state it be reduced to powder, it presents one form of pure silica. If in this state (in which it is perfectly insoluble in water) it be fused with three parts of carbonate of potash, it forms a glass which is soluble in water, and from this solution (formerly called *liquor of flints*) the concentrated acids throw down the silica in the form of a *gelatinous hydrate*; but if the solution be diluted, and the acid gradually added, the alkali may be neutralised without deposition of the silica; when, however, the solution is evaporated to dryness, the silica remains as insoluble as before. This solubility of hydrated or gelatinous silica, which, when dry, is perfectly insoluble, may serve to explain the occurence of silica in water, and its deposition in chalcedonic incrustations. But silica presents another remarkable character; i.e. that if we reverse the above proportions, and fuse together a mixture of one part of carbonate of potash and three of powdered rock-crystal or calcined flint, we then obtain a transparent and fusible compound, nearly insoluble in water, namely *glass*.

Plate glass and *window glass*, or, as it is commonly called, *crown glass*, are silicates of soda and lime; and *flint glass*, of which our common glass utensils are made, is a silicate of potash and lead. [GLASS.]

Silica, in its ordinary or *anhydrous* state, is insoluble in all acids except the *hydrofluoric*, which immediately acts upon it, and forms a gaseous compound, the *terfluoride of silicon*. Silica was long considered as an elementary form of matter; but Sir H. Davy found that when the vapour of potassium was brought into contact with pure silica heated to whiteness, silicate of potassa was formed, and a dark-coloured matter separated, which was afterwards found to be the base of silica, and to which the terms *silicium* and *silicon* have been applied. [SILICON.]

Silhouette (Fr.). In the Fine Arts, a name given to the representation of an object filled in of a black colour, and in which the inner parts are sometimes indicated by lines of a lighter colour, and shadows or extreme depths by the aid of a heightening of gum or other shining medium. This sort of drawing derives its name from its inventor, Étienne de Silhouette, the French minister of finance in 1759. Representations of this sort may be well enough taken from the shadow of a person thrown on a piece of paper placed against a flat surface or wall. The likeness may be still better taken, if on a reduced scale, by means of the instrument called a PANTAGRAPH.

The invention of what is called a *silhouette* is, however, ascribed to a remote period, being said to have been the method by which the daughter of Dibutades, a Greek potter at Corinth, drew the outline of the shadow of her lover's profile cast by her lamp on a wall; and has been placed at the time of the renewal of the Olympic games, shortly before the expulsion of the Bacchiads from Corinth, about 776 B.C. The father, it is said, cut out the plaster within the outline, took an impression from the space in clay and baked the squeeze with the rest of his pottery. The legend states that this original specimen of the plastic art was still preserved at Corinth when the city was sacked by Mummius 146 B.C. The Etruscan vases furnish to an amazing extent, and in boundless variety, some of the most beautifully drawn and elegant silhouettes that have ever been executed. [PAINTING.]

Silicates (Lat. silex, *a flint*). Compounds of silica (silicic acid) with certain bases; thus we have silicates of lime, magnesia, oxide of iron, &c., amongst minerals; and silicate of *lead* is an important ingredient in flint glass.

Silicificse. Substances petrified or mineralised by silica.

Silicious Sinter. A name given to the light cellular Quartz or opaline silica, which is deposited by the waters of hot springs, such as those of the Geysers in Iceland.

Silicite (Lat. silex, *flint*). The name given by Thomson to a yellowish-white Labradorite from Antrim in Ireland.

Silicon, Silicium. The peculiar non-metallic element which in combination with oxygen constitutes silica. Assuming silica to be a compound of 2 atoms of silicon and 4 of oxygen (Si_2O_4), silicon will be represented by the equivalent 14, and silica, consisting of 28 silicon and 32 oxygen, by 60. Silicon is obtained by the action of potassium or sodium on chloride of silicon or on silico-fluoride of potassium, at high temperatures, and exists in two conditions, amorphous and crystalline. Amorphous silicon is a brown powder, insoluble in and heavier than water, not acted on by sulphuric or nitric acids, but soluble in hydrofluoric acid and in caustic potash; when heated in oxygen it burns into silica. The preparation and properties of silicon have been described by Caron and Deville. (*Ann. de Chim. et Phys.* lxvii. 3me sér.) Like carbon, silicon occurs in the amorphous, graphitoidal, and crystalline forms. It also forms compounds with hydrogen, bromine, fluorine, and sulphur.

Silicula (Lat. dim. of siliqua, *a pod*). In Botany, a fruit exactly similar to that called a siliqua, except that it is shorter, and contains fewer seeds. It is never more than four times as long as broad, and usually much shorter.

Siliqua (Lat.). In Botany, a one or two-celled, many-seeded, linear fruit, dehiscent by two valves separating from a replum. The seeds are attached to two placentæ adhering to the replum, and opposite to the lobes of the stigma.

Silk (A.-Sax. seolc). A fine glossy thread or filament spun by various species of caterpillars or larvæ of the *Phalæna* genus. Of these, the *Phalæna atlas* produces the greatest quantity; but the *Phalæna bombyx* is that which is commonly employed for this purpose in Europe. The silkworm in its caterpillar state, which may be considered as the first stage of its existence, after acquiring its full growth (about three inches in length), proceeds to enclose itself in an oval-shaped ball, or cocoon, which is formed by an exceedingly slender and long filament of fine yellow silk, emitted from the stomach of the insect preparatory to its assuming the shape of the chrysalis or moth. In this latter stage, after emancipating itself from its silken prison, it seeks its mate, which has undergone a similar transformation; and in two or three days afterwards, the female having deposited her eggs (from 300 to 500 in number), both insects terminate their existence.

Many insects, however, besides the genus *Phalæna*, supply silk. Of these, one of the most important is the Ailanthus silkworm, the introduction of which into England has been strongly recommended. Some kinds of spiders also produce silk, but not in such quantities or in such a shape as to have any economical significance.

Raw silk is produced by the operation of winding off, at the same time, several of the balls or cocoons (which are immersed in hot water, to soften the natural gum on the filament) on a common reel, thereby forming one smooth even thread. When the skein is dry, it is taken from the reel and made up into hanks; but before it is fit for weaving, and in order to enable it to undergo the process of dyeing, without furring up or separating the fibres, it is converted into one of three forms—viz. *singles*, *tram*, or *organsine*.

Singles (a collective noun) is formed of *one* of the reeled threads, being twisted, in order to give it strength and firmness.

Tram is formed of two or more threads twisted together. In this state it is commonly used in weaving, as the *shoot* or *weft*.

Thrown silk is formed of two, three, or more singles, according to the substance required, being twisted together in a contrary direction to that in which the singles of which it is composed are twisted. This process is termed *organsining*; and the silk so twisted, *organsine*. The art of throwing was originally confined to Italy, where it was kept a secret for a long period. Stowe says it was known in this country since the 5th of Queen Elizabeth, 'when it was gained from the strangers;' and in that year (1562), the silk throwsters of the metropolis were united into a fellowship. They were incorporated in the year 1629; but the art continued to be very imperfect in England until 1719. [Post.]

1. *Historical Sketch of the Manufacture.*—The art of rearing silkworms, of unravelling the threads spun by them, and manufacturing the latter into articles of dress and ornament, seems to have been first practised by the Chinese. Virgil is the earliest of the Roman writers who has been supposed to allude to the production of silk in China, and the terms employed by him show how little was then known at Rome as to the real nature of the article:—

> Velleraque ut foliis depectant tenuia Seres.
>
> *Georg.* book ii. lin. 121.

But it may be doubted whether Virgil, in this line, refers to cotton rather than silk. Pliny, however, has distinctly described the formation of silk by the *bombyx*. (*Hist. Nat.* lib. xi. c. 17.) It is uncertain when it first began to be introduced at Rome: but it was most probably in the age of Pompey and Julius Cæsar, the latter of whom displayed a profusion of silks in some of the magnificent theatrical spectacles with which he sought at once to conciliate and amuse the people. Owing principally, no doubt, to the great distance of China from Rome, and to the difficulties in the

way of the intercourse with that country which was carried on by land in caravans whose route lay through the Persian empire, and partly, perhaps, to the high price of silk in China, its cost, when it arrived at Rome, was very great; so much so, that a given weight of silk was sometimes sold for an equal weight of gold! At first it was used only by a few ladies eminent for their rank and opulence. In the beginning of the reign of Tiberius, a law was passed—*ne vestis serica viros fœdaret*—that no man should disgrace himself by wearing a silken garment. (Tacit. *Annal.* lib. ii. c. 33.) But the profligate Heliogabalus despised this law, and was the first of the Roman emperors who wore a dress composed wholly of silk (*holosericum*). The example once set, the custom of wearing silk soon became general among the wealthy citizens of Rome, and throughout the provinces. According as the demand for the article increased, efforts were made to import larger quantities; and the price seems to have progressively declined from the reign of Aurelian. That this must have been the case, is obvious from the statement of Ammianus Marcellinus, that silk was, in his time (anno 370), very generally worn, even by the lowest classes. (Lib. xviii. c. 6.)

China continued to draw considerable sums from the Roman empire in return for silk, now become indispensable to the Western world, till the sixth century. About the year 550, two Persian monks, who had long resided in China, and made themselves acquainted with the mode of rearing the silkworm, encouraged by the gifts and promises of Justinian, succeeded in carrying the eggs of the insect to Constantinople. Under their direction they were hatched and fed; they lived and laboured in a foreign climate; a sufficient number of butterflies were saved to propagate the race, and mulberry-trees were planted to afford nourishment to the rising generations. A new and important branch of industry was thus established in Europe. Experience and reflection gradually corrected the errors of a new attempt; and the Sogdoite ambassadors acknowledged, in the succeeding reign, that the Romans were not inferior to the natives of China in the education of the insects, and the manufacture of silk. (Gibbon, *Decline and Fall*, vol. vii. p. 99.)

Greece, particularly the Peloponnesus, was early distinguished by the rearing of silkworms, and by the skill and success with which the inhabitants of Thebes, Corinth, and Argos carried on the manufacture. Until the twelfth century, Greece continued to be the only European country in which these arts were practised; but the forces of Roger, king of Sicily, having, in 1147, sacked Corinth, Athens, and Thebes, carried off large numbers of the inhabitants to Palermo, who introduced the culture of the worm and the manufacture of silk into Sicily. From this island the art spread into Italy; and Venice, Milan, Florence, Lucca, &c., were soon after distinguished for their success in raising silkworms, and for the extent and beauty of their manufactures of silk. (Gibbon, vol. x. p. 110; *Biographie Universelle*, art. 'Roger II.')

The manufacture of silk appears to have been introduced into Spain at a very early period by the Moors, particularly in Murcia, Cordova, and Granada. The last town, indeed, possessed a flourishing silk trade when it was taken by Ferdinand in the fifteenth century. The French having been supplied with workmen from Milan, commenced, in 1521, the silk manufacture; but it was not till 1564 that they began successfully to produce the silk itself, when Traucat, a working gardener at Nismes, formed the first nursery of white mulberry-trees, and with such success that in a few years he was enabled to propagate them over many of the southern provinces of France. Prior to this time, some French noblemen, on their return from the conquest of Naples, had introduced a few silkworms with the mulberry into Dauphiny; but the business had not prospered in their hands. The mulberry plantations were greatly encouraged by Henry IV.; and since then they have been the source of most beneficial employment to the French.

James I. was most solicitous to introduce the breeding of silkworms into England, and in a speech from the throne he earnestly recommended his subjects to plant mulberry-trees; but he totally failed in the project. This country does not seem to be well adapted to this species of husbandry, on account of the great prevalence of blighting east winds during the months of April and May, when the worms require a plentiful supply of mulberry-leaves. The manufacture of silk goods, however, made great progress during that king's peaceful reign. In 1629 it had become so considerable in London, that the silk throwsters of the city and suburbs were formed into a public corporation. So early as 1661 they employed 40,000 persons. The revocation of the edict of Nantes, in 1685, contributed in a remarkable manner to the increase of the English silk trade, by the influx of a large colony of skilful French weavers who settled in Spitalfields. The great silk-throwing mill mounted at Derby, in 1719, also served to promote the extension of this branch of manufacture; for soon afterwards, in the year 1730, the English silk goods bore a higher price in Italy than those made by the Italians, according to the testimony of Keysler. It would be impossible, within our limits, to give an account of the gradual progress of the silk manufacture from that period down to the present time. Upon this subject, the reader will find ample details in the *Commercial Dictionary*; meantime we may remark, that a great revolution was effected in the manufacture in 1825. Before that epoch the legislative enactments with respect to it were the most contradictory and impolitic that can well be imagined. The importation of foreign silks was prohibited under the severest penalties; but the advantage which this prohibition was believed, though most erroneously, to confer on the manufacturer,

would, under any circumstances, have been more than neutralised by the imposition of oppressive duties on the raw material. This vicious system was productive of a twofold mischief; for, by teaching the manufacturers to depend on custom-house regulations for protection against foreign competition, it made them indifferent about new discoveries and inventions, while, owing to the exorbitant duties on the raw material, and the want of improvement, the price of silks was maintained so high as to restrict the demand for them within comparatively narrow limits. In 1825, however, a new and more reasonable order of things was introduced. The duties on the raw material were greatly lowered; and at the same time foreign silk goods were allowed to be imported on payment of a duty of 30 per cent. ad valorem. This new system was vehemently opposed at its outset, and it was confidently predicted that it would occasion the ruin of the manufacture; but the result has shown the soundness of the principles on which it was bottomed. The manufacturers were now, for the first time, compelled to call all the resources of science and ingenuity to their aid; and the result has been that the manufacture has been more improved during the last thirty-five years than it had been in the whole previous century, and that it has continued progressively to increase. These duties were again modified by the Act 9 & 10 Vict. c. 23, by which foreign manufactured silks were charged at 15 per cent. ad valorem, or at an equivalent sum charged by weight. At the same time the duties on raw and thrown silk were repealed. In 1859, all duties on silk manufactures were abolished.

The total quantity of raw silk imported for home consumption in 1865 was nearly 8,000,000 lbs. But the annual importations vary exceedingly. Thus the quantity was more than 12,000,000lbs. in 1857, more than 10,000,000 lbs. in 1862; but only 5,655,401lbs. in 1864. The import of foreign manufactured silk has increased from 300,000lbs. the maximum, before the duty was repealed, to nearly 2,000,000lbs. in the year 1865. The price of the raw material has, however, undergone a considerable increase, the silk, raw and manufactured, imported into this country having been entered in 1865 at more than 17,600,000*l.* The number of persons engaged in the silk manufacture does not probably exceed 250,000. According to Mr. Fortune, the supply of silk derivable from China is all but inexhaustible, the increased demand for Chinese produce having hardly had any effect on the price of the raw material in the silk districts. The same, too, may be said of Japan; and if the attempts to naturalise various silk-producing insects, and especially the Ailanthus, in England, succeed, silken fabrics of various fineness and brilliancy will become plentiful and cheap.

Silk-cotton Tree. [BOMBAX.]

Silkworm. The larvæ of many species of Lepidopterous insects enclose themselves in a filamentary secretion called *silk*, but the name *silkworm* is given par excellence to that of the mulberry moth (*Bombyx mori*, Linn.), on account of the quality and abundance of the material of the case or *cocoon* in which the final metamorphosis takes place. The silkworm is a modified or domesticated variety of a species aboriginal, it would seem, to China.

Silk is a secretion of a pair of tubes called *sericteria*, which terminate in a prominent pore or *spinnaret* on the under lip of the caterpillar. Before their termination they receive the secretion of a smaller gland, which serves to glue together the two fine filaments from the sericteria: the apparently single thread being in reality double, and its quality being affected by the equality, or otherwise, of the secreting power of the two sericteria. When full-grown, the silkworm begins to spin, in some convenient spot affording points of attachment for the first-formed thread, which is drawn from one part to the other until the body of the larva becomes loosely enclosed by the thread. The work is then continued from one thread to another, the silkworm moving its head, and spinning, in a zigzag way, in all directions within reach, and shifting the body only to cover the part which was beneath it. The silken case so formed is called the *cocoon*. During the period of spinning the cocoon, which usually takes five days for its completion, the silkworm decreases in size and length; then casts its skin, becomes torpid, and assumes the form of the chrysalis. The main object of the silkworm breeder is to obtain cocoons of a large size, composed of a long, strong, very fine, even and lustrous thread. Different varieties of silkworm have thus been established, such as the *Sina*, *Syrie*, and *Novi* races in France.

Besides the silk from the *Bombyx mori*, stronger and coarser kinds are obtained, as in India, from the tussur moth (*Saturnia mylitta*), which feeds on the leaves of the *Terminalia catappa* and *Zizyphus jujuba*. The cloth woven from this silk is called *tussur cloth*, and is made chiefly at Midnapore. The *moonga silk* is from the *Bombyx saturnia*, which feeds upon the same trees as the tussur moth. The *Phalæna* (*Attacus*) *cynthia* produces the *eri* silk, woven into cloth at Assam: the larvæ feed on various leaves, but prefer those of the castor-oil plant (*Ricinus communis*). They have lately received attention under the name *Ailanthus silkworm*.

As in other instances of domesticated varieties, the silkworm is subject to diseases, of which that named the *muscardine* is the most disastrous to the sericiculturist. It has received great attention in Italy, from Dr. Bassi of Lodi, and in France from Andoin, Guerin-Méneville, Quatrefages, and others.

Sill (Sax. syl). In Architecture, the horizontal piece at the bottom of a framed case, such as that of a door or window. This word is also used to denote the bottom piece of a quarter partition. *Ground sills* are those timbers on the ground on which are placed the posts and superstructure of a timber building.

Sill of an Embrasure. In Fortification, the inner edge of the bottom or sole of an embrasure.

Sillimanite. An anhydrous silicate of alumina, found in a vein of gneiss at Chester near Saybrook, in Connecticut. It is of a dark grey colour passing into clove-brown, and either occurs in slender prisms, which are flattened and striated, or fibrous, columnar, or compact massive. Named after Professor Silliman.

Sillon (Fr.). In Fortification, a work raised in a ditch to defend it if too wide. It may be of any form, but must be lower than the works of the place, and higher than the covered way.

Silphium (Gr. σίλφιον). A genus of large-growing *Compositæ*, of which the most interesting species is the Compass-plant, *S. laciniatum*, the leaves of which *are said* to present their faces uniformly north and south, a statement which needs confirmation. The plant is also known as Pilot-weed, Polar-plant, Rosin-weed, and Turpentine-weed—the latter named from the abundant resin exuded by its stems, which grow to a height of three to six feet, as well as by the leaves, which are deeply pinnatifid. The tuberous roots of *S. læve*, a plant with smooth dock-like leaves, are eaten by the natives of the Columbia River valley. *S. perfoliatum* gets the name of Cup-plant, because the winged stalks of its opposite leaves are united together so as to form a cup with the stem in its centre.

Silphium is also the name given to a gum-resin supposed by some to be obtained from *Thapsia Silphion*, and by others from *Prangos pabularia*.

Silt. The name given to the sand, clay, and earth which accumulate in running waters.

Silurian. The name given by Sir Roderick Murchison to a series of rocks forming the upper subdivision of the sedimentary strata found below the old red sandstone, and formerly designated the *greywacke series*. These strata are well developed in that part of England and Wales formerly included in the ancient British kingdom of the *Silures*. [GEOLOGY.]

Siluridans (Lat. silurus; Gr. σίλουρος, *a sheath-fish*). The name of the family of fishes of which the genus *Silurus* is the type, and which includes the electric silurus (*Malapterurus electricus*). They are chiefly distinguished by the want of true scales, having merely a naked skin, or large osseous plates. A strong osseous spine forms the first ray of the dorsal and pectoral fins, except in the genus *Malapterurus*.

Silvanite. [SYLVANITE.]

Silvanus. A rural Italian deity; so called from Lat. silva, *a wood*. He also presided over boundaries.

Silvas (Span.; Lat. silva, *a wood*). A tract covered with forest vegetation, occupying at least a million of square miles in the tropical part of South America. A fifth part of this vast area is annually subject to inundation, and the exuberance of animal and vegetable life resulting from such conditions renders the whole district almost hopelessly unapproachable by civilised man. This tract is chiefly on the course of the Amazon, and the group of rivers connected with it.

Silver (Ger. silber). This metal, the *Luna* or *Diana* of the alchemists (☽), represented by the symbol Ag (argentum), and by the equivalent 108, is found *native*, and in a variety of combinations, the most common of which is the *sulphide*. *Native Silver* occurs massive; arborescent, capillary, and, sometimes, crystallised. It is seldom pure, but contains other metals, which affect its colour and ductility.

Silver is not unfrequently obtained in considerable quantities from *argentiferous sulphide of lead*, which is reduced in the usual way, the argentiferous lead being then fused in a shallow dish, placed in a reverberatory furnace, with a current of air constantly passing over its surface; in this way the lead is converted into oxide or *litharge*, and the silver is left in the metallic state.

The sulphides of silver are reduced by *amalgamation*. The ore, when washed and ground, is mixed with a portion of common salt, and roasted. During this operation arsenic and antimony are expelled, the copper and the iron are converted into oxides, chlorides, and sulphates, and sulphate of soda and chloride of silver are formed. The pulverised product is agitated with mercury, water, and filings or fragments of iron; in this operation the chloride of silver is decomposed, chloride of iron is formed which is washed away, and the silver and mercury combine into an amalgam, from which the excess of mercury is first squeezed out through leather bags, and the remainder driven off by distillation.

Pure Silver may be procured by dissolving standard silver in nitric acid, diluted with an equal measure of water. Immerse a plate of clean copper in the filtered solution, which occasions a precipitate of metallic silver; collect it upon a filter; wash it with a weak solution of ammonia, and then with water, and fuse it into a button.

Silver is of a more pure white than any other metal: it has considerable brilliancy, and takes a high polish. Its specific gravity varies between 10·4 and 10·6. It is so malleable and ductile, that it may be extended into leaves not exceeding a ten-thousandth of an inch in thickness, and drawn into wire infinitely finer than a human hair. Silver melts at a bright red heat, estimated at 1873° of Fahrenheit's scale, and when in fusion appears extremely brilliant. It resists the action of air at high temperatures for a long time, and does not oxidise; the *tarnish* of silver is occasioned by sulphuretted hydrogen. Pure water has no effect upon the metal; but if the water contains organic matter, it is sometimes slightly blackened. In the Voltaic arc it burns with a fine green light, and throws off abundant fumes. Exposed to an intense white-heat in the air, it evaporates, but in close vessels it is not sensibly volatile. If suddenly cooled, it crystallises during congelation, often shooting out like a cauliflower, and *spirting* particles of the metal out of the

crucible. This arises from the escape of oxygen, which the metal absorbs and retains whilst fluid, but suddenly gives off when it solidifies: this curious property of absorbing oxygen without combining with it, is prevented by the presence of a small quantity of copper.

There are three oxides of silver—a suboxide, Ag_2O; a protoxide, AgO; and a binoxide, AgO_2. But the protoxide only forms permanent and definite saline combinations. It is obtained by adding a dilute solution of potash to a solution of nitrate of silver. It is of a dark olive colour, and when heated to dull redness is reduced to the metallic state. It imparts a yellow colour to glass, and is employed in enamel and porcelain painting. Berthollet's *fulminating silver* is formed by the action of ammonia on this oxide. The best process for preparing it is to pour a small quantity of strong aqueous ammonia upon the oxide; a portion is dissolved, and a black powder remains, which is the detonating compound. It explodes with tremendous violence when rubbed or heated; nitrogen and water are evolved, and the silver is reduced. It is probably a nitride of silver, $=Ag_3N$. Fulminate of silver, which is the compound usually known as FULMINATING SILVER, has been already noticed.

When silver leaf is acted upon by gaseous chlorine in a humid state, it is gradually converted into a white chloride of silver; but this compound is usually procured by adding a solution of common salt to a solution of nitrate of silver. It falls in the form of a white curdy precipitate, which, by exposure to light, becomes violet-coloured, brown, and ultimately black, a property which has led to its employment in photography. Chloride of silver is so insoluble in water, that the minutest portion of any chloride in aqueous solution may be detected by it. It is insoluble in nitric and in cold sulphuric acid, but is abundantly soluble in solutions of ammonia, cyanide of potassium, and the alkaline hyposulphites.

Iodide and *Bromide* of silver are yellowish insoluble compounds, both of which have been found *native* in Mexico. They are principally important in reference to photography.

Nitric acid diluted with three parts of water, is the readiest solvent of silver: if the silver contains copper, the solution is bluish; or if gold, that metal remains undissolved in the form of a black powder. The solution of nitrate of silver is caustic, and tinges animal substances at first of a yellow $=A$, becoming, by exposure to light, purple or black. On evaporation, the solution yields anhydrous tabular crystals of a bitter metallic taste, which fuse when heated, and if cast into small cylinders, form the *lunar caustic* of pharmacy.

When some of the solutions of silver are reduced by certain essential oils, or by grape-sugar, a brilliant film of the metal may be so thrown down upon glass as to furnish a substitute for the amalgam of tin usually employed for mirrors. This coating is not to be depended upon for durability, but it has the advantage of being applicable to curved surfaces and the interior of spherical vessels.

Nitrate of silver is employed for writing upon linen, under the name of *indelible* or *marking ink*: and it is an ingredient in some of the liquids sold for changing the colour of hair. When taken internally, a discoloration of the skin often ensues, so that the surface of the body, and especially the parts exposed to light, acquire a leaden-grey colour.

Solution of nitrate of silver is a valuable test of the presence of chlorine, hydrochloric acid, and the soluble chlorides, with which it forms a white cloud when very dilute, but a flaky precipitate when more concentrated; the precipitate is soluble in ammonia, but insoluble in nitric acid.

Silver is dissolved by boiling sulphuric acid, and the resulting *sulphate of silver* is a difficultly soluble white salt. Upon the large scale, small portions of gold are separated from large quantities of silver, by heating the finely granulated alloy in sulphuric acid: the gold remains in the form of a black powder, and the sulphate of silver may be decomposed by the action of metallic copper, which precipitates metallic silver, and forms sulphate of copper.

Some of the *cyanides* of silver are used in the process of electro-plating.

Of the *alloys* of silver, the most important is that with *copper*; it constitutes plate and coin. By the addition of a small proportion of copper to silver, the metal is rendered harder and more sonorous, while its colour is scarcely impaired. When the two metals are in equal weights the compound is white: the maximum of hardness is obtained when the copper amounts to one-fifth of the silver. The *standard silver* of this country is composed of 92·5 silver + 7·5 copper; that of France of 90 silver + 10 copper; and in that of Prussia the alloy amounts to 25 per cent. The specific gravity of British standard silver is 10·3. The silver coins of the ancients, and many Oriental silver coins, are nearly pure; they only contain traces of copper and of gold. When silver alloyed by copper, such as standard silver, is exposed to a red heat in the air, it becomes black from the formation of a superficial film of oxide of copper; this may be removed by immersion in hot diluted sulphuric acid, and a film of pure silver then remains, of a beautiful whiteness; this is called *blanched*, *dead*, or *frosted silver*. The blanks for coin are treated in this way before they are struck, whence the whiteness of new coin, and the darker appearance of the projecting portions occasioned by wear, in consequence of the alloy showing itself beneath the pure surface; articles of plate are often deadened, *matted*, or *frosted* by boiling in bisulphate of potash (*sal enixum*), which acts in the same way as dilute sulphuric acid. *Lead* and silver form a very brittle dull-coloured alloy, from which the lead is easily separated by cupellation. When fused lead containing silver is suffered to cool slowly, the lead, which first concretes, forms granular crystals, and is nearly pure, while almost the

whole of the silver is contained in the liquid portion; in this way the separation of the two metals may to a certain extent be effected, especially upon the large scale. Silver amalgamates easily with *mercury*: when red-hot silver is thrown into heated mercury it dissolves, and when 8 parts of mercury and 1 of silver are thus combined, a granular crystalline soft amalgam is obtained. This amalgam is sometimes employed for *plating*; it is applied to the surface of copper, and the mercury being evaporated by heat, the remaining silver is burnished. The better kind of plating, however, is performed by the application of a plate of silver to the surface of the copper, which is afterwards extended by rolling. A mixture of chloride of silver, chalk, and pearlash, is employed for silvering brass: the metal is rendered very clean, and the above mixture, moistened with water, rubbed upon its surface. Plating by metallic precipitation from ammonio-chloride of silver is also frequently resorted to, but *electro-plating* with cyanide of silver now supersedes the other methods.

Assay of Silver.—The analysis of alloyed silver is in continual practice by refiners and assayers. It may be performed in the humid way by dissolving the alloy in nitric acid, precipitating with hydrochloric acid or chloride of sodium, and either reducing the chloride, or estimating the quantity of silver which it contains; every 100 parts of the carefully dried chloride indicating 75·33 of silver.

But a modification of this method is now generally resorted to, especially applicable in cases where the quality of the alloy is approximately known: it depends upon the precipitation of the silver by a *standard solution of common salt*, each 1,000 grains of which contain a sufficient quantity of salt to precipitate 10 grains of silver; so that, supposing the silver and the salt to be pure, 10 grains of silver dissolved in nitric acid, would be entirely precipitated by 1,000 grains of the standard solution. This process of humid assaying was introduced into the French Mint by Gay-Lussac, who has described it in detail. A description of this method by Mulder will also be found in the *Chemical News*, 1861, vol. ii. pp. 137-204.

Assayers generally determine the value of silver bars by the process of *cupellation*. Of the useful metals, three resist the action of air at high temperatures—namely, silver, gold, and platinum; the others, under the same circumstances, become oxidised; it might, therefore, be supposed, that alloys of the first three metals would suffer decomposition by mere exposure to heat and air, and that the oxidisable metal would burn into oxide. This, however, is not the case; for if the proportion of the latter be small, it is protected by the former; or, in other cases, a film of infusible oxide coats the fused globule, and prevents the further action of the air. These difficulties are overcome by adding to the alloy some easily oxidisable metal, the oxide of which is *fusible*. Lead is usually selected for this purpose. Supposing, therefore, that an *alloy of silver and copper* is to be *assayed* or analysed by *cupellation*, the following is the mode of proceeding: A clean piece of the metal (about 20 grains) is laminated, and accurately weighed. It is then wrapped in the requisite quantity of *pure* sheet lead, apportioned by weight to the *quality* of the alloy, and placed upon a small *cupel*, or porous shallow crucible, made of bone-earth. The whole is then placed within a *muffle*, heated to bright redness; the metals melt, and, by the action of the air which plays over the hot surface, the lead and copper are oxidised, and their fused oxides are absorbed by the cupel, and, if the operation has been skilfully conducted, a button of pure silver ultimately remains, the completion of the process being judged of by the cessation of the oxidation and motion upon the surface of the globule, and by the brilliant appearance assumed by the silver when the oxidation of its alloy ceases. The button of pure silver is then suffered to cool gradually, and its loss of weight will be equivalent to the weight of the alloy which has been separated by oxidation, a certain allowance being made for a small loss of silver, which always occurs, partly by evaporation, and partly by absorption in the cupel.

Silver Black. An earthy form of Silver Glance, of a dark bluish-black colour, found in several Saxon and Hungarian mines.

Silver Glance. A valuable ore of silver; composed of 87·1 per cent. of silver, and 12·9 sulphur. It is of a blackish-grey colour, but acquires a superficial iridescent tarnish on exposure; opaque, with a metallic lustre; flexible but difficultly frangible; malleable and sectile, yielding easily to the knife and cutting like lead. It is found in various cubical forms; also dendritic, stalactitic, and amorphous, in several Cornish mines.

Silver or Glass Speculum. A speculum of glass silvered in the manner described in art. SILVERING, and used in reflecting telescopes instead of a metallic reflector. [TELESCOPE.]

Silver Grain. The glittering plates observed in the wood of many Exogens, and caused by the division of the medullary plates.

Silvering. The art of fixing thin films of silver on various surfaces. Copper may be coated with silver by first amalgamating the latter with mercury, rubbing the compound over the cleaned copper, and then volatilising the mercury by heat. Glass surfaces may be silvered by covering with an alkaline solution of oxide of silver, and then adding a reducing agent such as milk-sugar; this process gives a very brilliant surface. Ordinary mirrors, or *looking-glasses* as they are generally termed, owe their reflecting powers to a surface of tin and mercury, and not to pure silver; hence the process may, in this case, be called *quicksilvering* rather than silvering, though the latter name is generally adopted. Quicksilvering consists in placing on a flat table a sheet of tin-foil, adding some mercury, and rubbing

it gently over the tin till amalgamation is effected, then sliding on the sheet of glass, and applying considerable pressure for two or three days; excess of quicksilver is thereby removed, and the residual amalgam adheres firmly to the glass.

Silvic Acid. A name applied to that portion of common resin or colophony which is most readily soluble in cold alcohol. Its combinations with salifiable bases have been termed *silvates*. It is crystallisable, and its alcoholic solution reddens litmus.

Silybum (Gr. σίλυβος, or σίλλυβος). A genus of thistle-like *Compositæ*, the most familiar of which is *S. Marianum*, the Milk Thistle, which grows to the height of three or four feet or more, with large spreading wavy spinous leaves, of which those next the root are pinnatifid, and variegated with green and milk-white. The specific name *Marianum* was given to this plant to preserve the legend that the white stain on the leaves was caused by the falling of a drop of the Virgin Mary's milk. It was formerly cultivated, the young leaves being used as a spring salad, the root boiled as a pot-herb, and the heads treated like the heads of the artichoke. It grows wild in waste places in many parts of England, and still retains its place in old-fashioned gardens.

Simaba. The native Guiana name of a plant representing a genus of *Simarubaceæ*, consisting of trees and shrubs, having the leaves alternate, and either simple or ternate or pinnate, and the flowers axillary.

S. Cedron, a small tree of New Granada, which bears a fruit about the size of a swan's egg, containing only one seed, possesses valuable remedial properties. The kernel of this seed, the Cedron of commerce, which looks like a blanched almond but is larger, appears to have been known to the inhabitants from time immemorial as a remedy for the bites of serpents. Its reputation is probably owing partly to its febrifugal powers in intermittent fever, it being successfully prescribed in that disease by the physicians of New Grenada, a country abounding in forests of quina-trees. The natives universally believe that it will neutralise the poison even of the most dangerous reptiles. On the latter account it is so much valued, that there are scarcely any persons in New Grenada or the adjacent states who have not a piece of this seed, which they always carry with them; and a single seed will sell for four shillings. The active principle on which the medicinal qualities of the Cedron depend has been separated by M. Lecoy, who has named it *cedrine*. Every part of the plant, but especially the seed, is, owing to its presence, intensely bitter.

Simaruba (its name in Guiana). A genus of *Simarubaceæ*, consisting of tropical American trees, one of which, *S. amara*, a native of the West Indies and Guiana, yields the drug known as Simaruba-bark, which is, strictly speaking, the rind of the root. It is employed as a bitter tonic in diarrhœa and dysentery, as well as in various forms of indigestion. In large doses it is said to act as an emetic purgative and diaphoretic. *S. versicolor*, a Brazilian species, has similar properties. The fruits and bark are used as anthelmintics, and an infusion of the latter is employed in cases of snake-bite. The plant is intensely bitter, and its powdered bark has been employed to kill vermin.

Simarubaceæ (Simaruba, one of the genera). A natural order of arborescent or shrubby Hypogynous Exogens, inhabiting the tropics, and belonging to the Rutal alliance. The species are exceedingly bitter. The wood of QUASSIA is well known. The *Simaruba versicolor* of St. Hilaire, called *Paraiba* in Brazil, possesses such excessive bitterness that no insects will attack it; and *Picræna excelsa*, another species of the order, is employed in medicine for the same property. The order is known by the alternate stipulate leaves, the few-seeded apocarpous fruit, the dry inconspicuous torus, and the exalbuminous seeds. The species are nearly all natives of tropical America, India, or Africa.

Simia (Lat. *an ape*, from simus, Gr. σιμός, *flat-nosed*). The generic name applied by Linnæus to all the Quadrumanous Mammals, except the Lemurs. The Linnæan *Simiæ* are divided into numerous subgenera, to none of which the name Simia is now applied, except by some modern naturalists to the orang-utan (*Simia satyrus*) and the mias Kassar (*S. morio*).

Similar (Lat. similis, *like*). In Geometry, similar figures are those which have the same *shape*. More accurately defined, similar rectilineal figures or polygons are such as have their angles respectively equal, and the sides about the equal angles proportional. Of these two conditions, triangles alone necessarily satisfy the one when they satisfy the other. Similar polyhedrons are those which are contained by the same number of similar faces, similarly situated with respect to each other, and having the same mutual inclinations. Generally, two figures are said to be similar when one can be moved so that like directed and co-initial radii vectores of the two are proportional. In this position the common origin of the radii vectores is termed a *centre of similitude*. Two similar figures can be brought into this position in innumerable ways, each way corresponding to a different centre of similitude, and when this can be effected by the mere *translation* of one figure without rotation, the figures are said to be *similar* and *similarly situated*. All circles are similar, as are also all spheres. The latter, too, are similarly situated, as are also the former, provided they are in the same plane. All ellipses are similar whose principal axes have the same ratio, and they are similarly situated when these axes are parallel. All parabolas are similar. The equations of two curves or two surfaces being given, it is easy, from the above definition, to discover the relations which must exist between their co-

efficients in order that the figures may be similar.

Simile (Lat. *like*). In Rhetoric, the same as COMPARISON.

Similiter (Lat. *in like manner*). In Law, the technical designation of the form by which either party, in pleading, accepted the issue tendered by his opponent. The one having concluded his plea, replication, &c. by *putting himself upon the country*, i. e. praying that the truth of the facts may be enquired of by a jury, the other added the similiter, which was in the form, 'And the said A. B. as to the plea &c. of the defendant (or plaintiff) above pleaded, and whereof he hath put himself upon the country, doth the like.' But this technicality was superseded by the Common Law Procedure Act, 1852. [PLEADING.]

Similitude (Lat. similitudo, from similis). In Geometry, the relation which similar figures bear to each other. The *centre of similitude* of two similar figures is a point such that like or oppositely directed radii vectores from it to the two figures are proportional. [SIMILAR.] In the case of two circles, there are two centres of similitude; one divides the line joining the centres of the circles externally, the other internally, into segments which are proportional to the conterminous radii; the former is called the *external*, and the latter the *internal centre of similitude*. If the circles lie wholly without each other, the centres of similitude are obviously the intersections of common tangents. If A and B be the centres of two circles, and S a centre of similitude, a line drawn through S so as to cut the circles in a, a_1 and b, b_1 respectively, will determine two pairs of parallel radii, say Aa, Bb and Aa_1, Bb_1. In such a case a and b as well as a_1 and b_1 are said to *correspond directly*, whilst a and b_1 as well as a_1 and b *correspond inversely*. Similarly a secant through any two points of one circle corresponds directly to the secant through the directly corresponding points of the other, and inversely to the secant through the inversely corresponding points. This being understood, it can be easily shown that two directly corresponding secants are always parallel, whilst two secants which correspond inversely intersect one another on the radical axis of the two circles. It is easy to see how this property becomes modified when the secants become tangents. The line joining the points of contact of a circle which touches two other circles always passes through a centre of similitude of the latter. The circle whose diameter is the segment between the two centres of similitude is sometimes called the *circle of similitude*. Viewed from any point on this circle, the two original circles appear equally large.

The six centres of similitude of three circles, taken in pairs, lie three by three on four lines, which are called *axes of similitude*. The line upon which the three external centres of similitude are situated, is distinguished as the *external axis of similitude*. In general, eight circles can be drawn to touch three given circles. Taken in pairs, these eight circles have the four axes of similitude for radical axes. The centres of any two circles which form a pair lie on the perpendicular let fall from the radical centre of the three given circles upon one of their axes of similitude. (Salmon's *Conics*, and Mulcahy's *Principles of Modern Geometry*, Dublin 1862.)

Simonians. The name given to the followers of Simon Magus, who is described as pretending to be the great virtue and power of God sent from heaven to earth. Their system was a medley of the philosophy of Plato, the mythological fables of the heathens, and of Christianity. The sum of their doctrines, as enjoined by their founder, was, that from the Divine Being flow various orders of eternal natures, subsisting in the plenitude of the Divine essence; that beyond these are different classes of intelligences, to the lowest of which belongs the human soul; that matter is the most remote production of the emanative power, which, on account of its distance from the fountain of light, possesses sluggish and malignant qualities, which are the cause of evil; that it is the great design of philosophy to deliver the soul from its imprisonment in matter, and that for this purpose God had sent us one of the first *æons* into the world. They believed also in the transmigration of souls, and denied the resurrection of the body.

Simonians, Saint. [SAINT SIMONIANS.]

Simony. In Law, an unlawful contract for the presenting a clergyman to a benefice. When such presentation is made corruptly, for money, gift, or reward, by stat. 31 Eliz. c. 6, such presentations are void, and the crown shall present for that turn; and by 12 Anne st. 2. c. 12, if anyone, for money or profit, procures in his own name the next presentation to any living ecclesiastical, and is presented thereupon, the contract is simoniacal. But the sale of an advowson is not simoniacal, whether the benefice be full or not, unless made with a corrupt view to the next presentation, though if the benefice be not full, the next presentation does not pass by a conveyance of the advowson. The term is derived from Simon Magus, but it is generally remarked that the practices against which our laws are directed bear no precise similarity to the offence ascribed to him in the Acts of the Apostles, and the purchase, *on behalf* of a particular clergyman, of the next presentation to a benefice, is a matter frequently arranged.

Simoom. A hot arid wind which blows in Arabia, Syria, and the adjacent countries, and chiefly about the time of the equinoxes. The simoom, which is identical with the *khamsin* of Syria, and the *samiel* of the Turks, and resembles in many respects the *sirocco* and *sorana* of other countries, derives its qualities from blowing over sandy deserts heated intensely by the sun. Sometimes it blows in squalls, bearing along with it quantities of burning sand and dust. In the desert it is greatly dreaded; and the only chance of safety which the traveller has

is to fall down with his face close to the ground, and to continue as long as possible without drawing breath. It is described by Bruce, Volney, Charind, Malcolm, and other travellers.

Simple Contract Debt. In Law, where the contract on which the debt arises is neither ascertained by matter of record (as by the judgment of a court of law) nor by deed or special instrument (as mortgages, bonds, &c.), but by oral evidence, bill of exchange, promissory note or other writing not under seal.

Simplicimanes (Lat. simplex, *simple*; manus, *a hand*). A name given by Latreille to a tribe of Caraboid beetles, comprehending those in which, in the male, the two anterior tarsi are dilated.

Simplicirostres (Lat. simplex; rostrum, *beak*). The name of the first group of *Natatores*, or swimming birds, in the system of Lilljeborg, including those in which the beak is without laminæ, and in which both parents sit on the eggs, take care of the young and carry food to them: the Penguins, Gulls, and Pelicans are examples of this group.

Simplicity (Lat. simplicitas, from simplex). In the Fine Arts, that quality in works of art through which the elements are arranged in the most natural order, and in which the ideas and images are so presented to us that the principal objects are not eclipsed by the accessories, and the details are in due subordination to the whole. Simplicity is the reverse of excess and exaggeration, and may be properly called a negative quality in art.

Simultaneous Equations. A name given to such equations as are satisfied by a common system of values ascribed to the variables or unknown terms which they involve. When the equations are independent, and equal in number to the number of variables they involve, such a common system of values or *roots* is always possible. All works on algebra explain methods of finding these roots. [ELIMINATION; RESULTANT.]

Simultaneous Differential Equations are such as can be satisfied, simultaneously, by a system of relations between the variables. The latter constitutes the *complete solution* when it involves the requisite number of arbitrary constants. The most important class of such differential equations is that in which as in the problems of physical astronomy, there is but one independent variable (e.g. the time) and the number of equations is equal to the number of dependent variables (e.g. co-ordinates of celestial bodies).

A system of n differential equations of the first order and degree connecting $n+1$ variables $x, x_1, \ldots x_n$ may always be made to assume the symmetrical form

$$\frac{dx}{X} = \frac{dx_1}{X_1} = \frac{dx_2}{X_2} \ldots = \frac{dx_n}{X_n}$$

where X, X_1, &c. are functions of the $n+1$ variables. The important problem of its complete solution has been shown by Lagrange and Jacobi (Crelle's *Journal*, t. ii.) to depend upon that of an ordinary differential equation of the n^{th} order between two of the variables; whence it follows that the complete solution in question consists of n equations connecting the $n+1$ variables with n arbitrary constants.

When X, X_1, X_2, &c., are linear functions of the variables, the above system is susceptible of integration by an elegant and symmetrical method, indeed more generally the complete solution of the system,

$$\frac{dx_1}{X_1+T_1} = \frac{dx_2}{X_2+T_2} = \ldots \frac{dx}{X_n+T_n} = \frac{dt}{T},$$

(where T, T_1 &c. . . . are any functions of the independent variable t, and X_1, X_2, &c. are linear and homogeneous functions of the dependent variables x_1, x_2 &c. . . . x_n) may always be made to depend upon that of a linear differential equation of the first order in two variables, and upon the solution of an algebraic equation of the n^{th} degree.

A system of simultaneous differential equations of an order higher than the first, may always be reduced to a system of the first order, by introducing new variables for each of the differential coefficients in the original system except those whose orders are the highest of their kind. The number of dependent variables, and therefore of equations, in the transformed system will be equal to the sum s of the indices of the several differential coefficients of highest order in the original system. The complete solution, therefore, will consist of s equations involving an equal number of dependent variables and each provided with an arbitrary constant. If from this system the $s-n$ introduced variables be eliminated, there will remain n equations connecting the original $n+1$ variables with s arbitrary constants, which system will constitute the complete solution required.

Simurg. [Roc.]

Sin Offering. In the Old Testament, the sacrifice of propitiation for the sin of the people, enjoined in Lev. iv. and considered different from the trespass offering (ibid. xiv.), thought to be appropriate to special cases of negligence only.

Sinapine. A peculiar organic base extracted from mustard seed (*Sinapis alba*). It is a white crystallisable inodorous substance, of a bitter taste, accompanied by the flavour of mustard. Its formula is $C_{32}H_{23}NO_{10}$.

Sinapis (Gr. σίναπι, *mustard*). A genus of Cruciferous herbs, containing several species of interest, the most important of which are those called Black and White Mustard.

The Black Mustard, *S. nigra*, yields the greater portion of the condiment so generally used in this country under the name of mustard. The plant is indigenous, and is largely cultivated in Yorkshire and Durham. The seeds are of reddish-brown colour, and mixed with those of *S. alba* they are crushed between rollers, and subsequently pounded and sifted twice or oftener. From the residue left on the sieve a

fixed oil is obtained by pressure. The powdered mustard is usually mixed with a considerable quantity of wheaten flour and a small quantity of turmeric powder—admixtures readily detected by the microscope. The chemical ingredients of mustard-seeds are somewhat complex. Among them is a peculiar acid called myronic acid, noticeable as containing a proportion of sulphur, and which, when mixed with water and a peculiar substance called *myrosine* (analogous to albumen), also found in mustard-seeds, yields Volatile Oil of Mustard, which has no separate existence in the seeds, but is formed artificially in the manner just stated. This oil is very acrid, and has been employed as a rubefacient. The fixed oil before mentioned as existing in the seed itself has little or no acridity, and has been used as a purgative and vermifuge.

In modern medicine mustard is most frequently employed in the well-known form of poultice, a safe and most valuable application where a speedy result is desired, but one which if allowed to remain on too long, especially in persons who are not sensitive to pain, may produce ulceration and gangrene. Internally, it is employed as an emetic in narcotic poisoning, &c. As a condiment it is valuable for its stimulant effects, which render it useful in cases of weak digestion, or as an adjunct to fatty and other indigestible articles of food.

The White Mustard, *S. alba*, also indigenous in this country, has seeds larger than those of the Black Mustard, and of a yellow colour externally. Chemically they differ in containing a crystalline substance known as *sulpho-sinapisin*. Moreover, their myrosine yields with water a pungent oil of a different character from the volatile oil of mustard previously mentioned. The seeds have similar properties to those of *S. nigra*. They have been recommended to be swallowed whole as stomachics and laxatives, a process by no means free from danger. The seed-leaves or cotyledons of this plant, together with those of *Lepidium sativum*, form the well-known agreeable salad known as mustard and cress. The facility and speed with which this salad may be grown at all seasons and in all places, together with its wholesome properties, are great advantages.

Various other species are cultivated for their leaves or for the oil derived from the seeds. Among them are, *S. chinensis*, *S. dichotoma*, *S. pekinensis*, *S. ramosa*, and *S. glauca*. The seeds of *S. arvensis*, the Common Charlock, yield a good burning oil, and in France its leaves are used as forage for cattle. The leaves of *S. cernua* are eaten in Japan, while the seeds furnish an oil. *S. juncea* is cultivated for its oil, called in India Soorsa; it is used for burning, and also for rubbing the body in illness. *S. nigra*, which grows some ten or twelve feet high in Palestine, is regarded by some as the Mustard of Scripture, in preference to *Salvadora*.

Sinapism. A mustard poultice.

Sinciput (Lat.). The anterior region of the upper part of the head, from the vertex to the eyes in Mammals, and from the vertex to the base of the beak in birds.

Sine (Lat. sinus). In Trigonometry, the ratio of the perpendicular to the hypothenuse of any right-angled triangle is termed the sine of the angle at the base. [TRIGONOMETRY.]

The *sine of an arc*, by means of which the sine of an angle used to be defined, is the half of the chord of the doubled arc; in other words the perpendicular let fall from one extremity of the arc upon the radius to the other extremity. Ptolemy, in the graphical constructions in the *Analemma*, makes use of the semichords instead of the chords; but the introduction of the sines into trigonometrical calculation was an important improvement, of which the credit appears to be due to the Arabian astronomer Albategnius. (Delambre, *Astronomie du Moyen Age*, p. 12.) The term *sine* has been variously derived; the Arabic name is *gib*, or *dgib*, signifying *a fold*, of which *sinus* is the Latin translation. (Hutton's *Mathematical Tables*.)

Sine Die (Lat. *without day*). In Legal and Parliamentary usage, an adjournment or prorogation *sine die* means without any specified day for resuming the subject or reassembling.

Sine quâ non (Lat. *without which not*). A phrase used to signify any indispensable condition.

Sinecure (Lat. sine curâ, *without care*). In Politics, an office without any duties attached to it. The term is properly ecclesiastical, and applied to a benefice without cure of souls; in which sense it is also still employed.

Singers of Germany. A general title, which may be regarded as including the MINNESINGERS as well as the Meister-singers of Germany. The latter became known in the fourteenth century, and are traced to the institutions of the twelfth century, called *singing schools*, for the promotion of popular music. They differed from the Minnesingers by confining themselves to didactic and moral subjects, and regulated their verse by minute and pedantic laws, without any other idea of excellence than that of conformity to rule. They are said to have originated at Mentz, and were incorporated by Charles IV. in 1378 under the name of Meistergenossenschaft. (Hallam, *Literary History*, part. i. ch. i.)

Singles. [SILK.]

Singular Roots of a Quantic. This term is applied to any system of values of the variables which reduce to zero each of the first derived functions of the quantic. (Salmon's *Higher Algebra*, p. 45.) The vanishing of the discriminant always indicates the existence of singular roots, which in the case of ternary and quaternary quantics are simply the co-ordinates of a double point on the corresponding curve or surface. [DISCRIMINANT.]

Singular Solutions. A singular solution of a differential equation of the first order, in two variables x and y, is a function of x and

y which satisfies that equation, but which is not deducible from the *general solution* or *complete primitive* by giving to the arbitrary constant which the latter involves a value absolutely independent of the variables. When the complete primitive is known, every singular solution may be deduced from it by giving to the constant c therein a value which will satisfy one or both of the conditions

$$\frac{dy}{dc} = 0, \frac{dx}{dc} = 0,$$

and conversely any solution thus obtained, and not obtainable from the primitive by giving c a constant value, is a singular solution. Geometrically a singular solution ordinarily represents the *envelope* of all the curves represented by the complete primitive, when the value of its arbitrary constant is changed. There are, however, other kinds of singular solutions whose relation to the primitive is of a more complicated character. An elaborate investigation of these will be found in Boole's *Differential Equations*, London 1859.

The singular solutions of a differential equation may also be detected without a previous knowledge of the complete primitive. To do so in the case above referred to, it is necessary to examine what relations will satisfy the differential equation, and at the same time render the partial differential coefficient of $\frac{dy}{dx}$ (taken according to y) or that of $\frac{dx}{dy}$ (taken according to x) infinite.

Singular solutions were examined, to some extent, as early as 1694 by Leibnitz, as also by Brook Taylor in 1715, by Clairaut in 1734, and by Euler in 1756. Laplace, however, in 1772 (*Mémoires de l'Académie des Sciences*) appears to have been the first to consider the general problem of the deduction of the singular solution from the differential equations; Lagrange (*Calcul des Fonctions*), Cauchy (*Moigno's Calcul Intégral*, Paris 1844), De Morgan (*Cambridge Phil. Trans.* vol. ix.), Boole, and others, have since written on the same subject.

Differential equations of higher order also often possess singular solutions, i.e. are satisfied by relations between the variables which are not deducible from the complete primitive except by supposing one or more of the arbitrary constants to be variable. The discovery of such solutions depends upon that of *singular integrals* of the differential equation under consideration, i.e. of differential equations of lower order which satisfy the given equation, and possess the above explained property of singularity.

A singular solution, as defined by Lagrange in his *Calcul des Fonctions*, of a partial differential equation of the first order, say

$$z = F(x, y, p, q),$$

where x and y are independent variables, and p and q denote the partial differential coefficients $\frac{dz}{dx}, \frac{dz}{dy}$, is found by eliminating the arbitrary constants a and b from its complete primitive, say $z = f(x, y, a, b)$, by means of the relations $\frac{df}{da} = 0$, and $\frac{df}{db} = 0$, or by eliminating p and q directly from the given differential equation by means of the relations $\frac{dz}{dp} = 0$, $\frac{dz}{dq} = 0$. Geometrically, the singular solution represents the envelope of the surface, whose equation is the complete primitive, when the parameters a and b, which the latter involves, are supposed to be *independent* of each other.

Singular Term. In Logic, a term which stands for one individual. A singular proposition is one which has for its subject either a singular term, or a common term limited to one individual by a singular sign. [PROPOSITION; TERM.]

Singularities of Curves and Surfaces. Certain distinguishing properties by means of which curves and surfaces may be classified. Multiple and stationary points, tangents, or tangent planes, &c., are examples of such singularities. Each of these is described in its appropriate place; here it may suffice to record certain important equations, connecting the ordinary singularities of plane curves, and known as Plücker's *equations*, they having been first established by that mathematician in his *Theorie der Algebraischen Curven*, Bonn 1839. If m denote the order, n the class, and δ, τ, κ, and ι respectively the number of double points, double tangents, stationary points, and stationary tangents of a curve, the equations in question are:—

$$n = m^2 - m - 2\delta - 3\kappa, \quad \iota = 3m^2 - 6m - 6\delta - 8\kappa$$
$$m = n^2 - n - 2\tau - 3\iota, \quad \kappa = 3n^2 - 6n - 6\tau - 8\iota;$$

which are equivalent, merely, to three independent equations, by means of which any three of the six numbers which they involve may be found, when the remaining three are known. The singularities here considered are called *ordinary*, because, without limiting the generality of a curve of given order or class by any special hypothesis, they may all present themselves.

In the *Cambridge and Dublin Mathematical Journal*, vol. v. Prof. Cayley has given the extension of Plücker's equations to non-plane curves.

Sinister (Lat. *left*). This word is commonly used in the sense of unlucky or unpropitious. Both in Greek and Roman divination the good omens were held to come from the east: and as the Greek augurs looked to the north, the west, or quarter of bad omens, was to their left. The Roman augur faced the south, and had the quarter of good omens on his left hand. Hence Virgil (in *Georg.* iv. 7), when he calls the propitious deities *laeva*, follows the Roman system of augury; but he

uses the word *sinister*, as the Greeks used ἀριστερός (*Odyss.* 20, 242) for things of evil omen. (*Ecl.* i. 18. &c.) [AUGURS; OMENS.]

Sinkanite. A name for the mineral Johnstonite, after one of its localities, Neu Sinka in Transylvania.

Sinking Fund. [FUND, SINKING.]

Sinopite. The Bole of Sinope. It is the *Sinopian Earth* of the ancients.

Sinople. A ferruginous Jasper, of a bright brick-red colour, found at Schemnitz in Hungary.

SINOPLE. In Heraldry, the Continental designation for the colour green; by English heralds called *vert*. The name is said to be derived, through the Crusaders, from the town of Sinope, in Asia Minor.

Sinter. A German word implying a *scale*. *Calcareous sinter* is a variety of carbonate of lime composed of successive concentric layers. *Silicious sinter* is a variety of Common Opal.

Sintoos. In Japan, the adherents of the Sinsyn (i.e. worship of the gods), the ancient religion of the country, in which the chief deity is the sun-goddess Ten-sio-dai-yin. This divinity is invoked through inferior deities called KAMI.

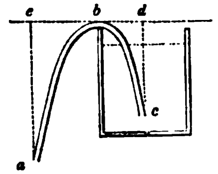
Sinuous (Lat. sinuosus, from sinus, *a curve*). In the Fine Arts, of a serpentine or undulating form.

Sinus (Lat.). In Zoology, depressions which exist in various bones or other hard parts are so called. The veins of the dura mater of the brain are also called *sinuses*.

Sinuses, Frontal. Large cavities, divided into two portions by a perpendicular osseous partition, and lined with a continuation of the pituitary membrane, secreting the lubricating mucus discharged into the nose. The extent of this frontal sinus is by no means dependent on or coincident with the degree of elevation of the supraciliary or superorbital ridges. In many recent crania of savage and barbarous men a considerable frontal elevation exists, in which no extraordinary expansion of the sinuses occurs; and Sir William Hamilton has demonstrated that it is erroneous to suppose that the extent of the sinus is indicated by a ridge, or crest, or blister, in the external bony plate. Such a protuberance has no certain or even probable relation to the extent, depth, or even existence of any vacuity beneath. In the Papuans and Australians, who approach nearest to the ape in their cranial conformation, no frontal sinus whatever exists, whilst a rather considerable frontal elevation is exhibited; in the chimpanzee in which a remarkable superorbital developement exists, no frontal sinuses have been discovered.

Sinusoid. The transcendental curve whose equation is $y = \sin x$. The curve undulates incessantly and symmetrically between two lines parallel to the abscissa axis and at the distance unity from the same. At intervals equal to π the curve crosses the abscissa axis at an angle of 45°.

Siphon or **Syphon** (Gr. σίφων, *a reed* or *tube*). In Hydraulics, a simple and well-known instrument, chiefly used for the purpose of drawing off liquids from casks. The siphon is simply a bent tube, $a\ b\ c$, having one end longer than the other. To use the siphon, the tube is in the first place filled with the liquid, and the open end a stopped by the hand, or by a cock, in which state the liquid will not flow from the other extremity. The end c is then immersed in the liquor, and the stop removed from a; upon which, if a be at a lower level than c, the liquid will immediately begin to flow out at a, and will continue to flow until the vessel is drained down to the level of c.



The principle of the siphon may be explained as follows: The lowest section of the liquid within the tube at the extremity c is subjected to two unequal pressures in opposite directions: first the pressure due to the liquid in the branch $b\ c$, which pressure is equal to the weight of a column whose length $c\ d$ is equal to the height of b above c, and tends to force the liquid out of the tube; secondly, the pressure of the external liquid at c, which is equal to the atmospheric pressure, or the weight of a column of liquor of about 34 feet in height, together with the weight of the column reaching from c to the surface of the liquid in the vessel, which, however, we may leave out of consideration. Hence, if the line cd be less than 34 feet (if the liquid be water), the last pressure will preponderate, and the liquid will be forced into the tube by a pressure equal to the weight of the atmosphere diminished by the weight of a column of the fluid equal to cd. In like manner, the pressure upon a section of the liquid at a is equal to the weight of the atmospheric column diminished by the weight of a column of the liquid equal in height to ae. If, therefore, ae be greater than cd, the pressure at c will be greater than the pressure at a, and the liquid will be forced through the tube.

From this explanation it is obvious that the limits within which the siphon can act are determined by the specific gravity of the liquid. Water cannot be raised by the siphon to a greater height than 34 feet, nor mercury to a greater height than 30 inches. It is also obvious that the comparative diameters of the two branches, and their oblique lengths, are of no importance, the action depending only on the difference of their perpendicular heights.

Sometimes the siphon is made with both branches equal, and turned up at the extremities; in which case, so long as the extremities are kept on the same level, it will continue always full and ready for use. This form of the instrument is called the *Wurtemberg*

siphon, from its having been first used in that country.

Siphon. In Zoology, the name of the membranous and calcareous tubes which traverse the septa and the interior of Polythalamous shells. The term is also applied to the tubular prolongation of the mantle in certain Univalve and Bivalve Molluscs; and by Latreille to the mouth of certain Suctorious, Crustaceous, and Apterous insects.

Siphonandraceæ (Siphonandra, one of the genera). A name proposed by Dr. Klotzsch for an order of Monopetalous Exogens, including *Vacunum*, *Andromeda*, &c. The group is not generally adopted.

Siphonapterans (Gr. σίφων, and ἄπτερος, *without wings*). A name given by Latreille to an order of insects, including those Apterous species which have a mouth in the form of a siphon.

Siphonia (Gr. σίφων). A genus of *Euphorbiaceæ*, and the source of the greater part of our supply of Caoutchouc. There are about half a dozen species. They are trees containing a milky juice in more or less abundance, though they do not all yield caoutchouc of good quality. One of them, *S. elastica*, is a

Siphonia elastica.

native of French Guiana, and the remainder of the Amazon and Rio Negro districts of Brazil. They are called Seringa-trees by the Brazilians, from the Portuguese word *seringa*, signifying a syringe or clyster-pipe, the caoutchouc having first been used for making those articles. The bulk of the caoutchouc at present exported from Pará, whence our chief supply is derived, is obtained from *S. brasiliensis*, which is common in the forests of that province; but that brought down to Pará from the Upper Amazon and Rio Negro is derived from *S. lutea* and *S. brevifolia*. These three species are all slender smooth-stemmed trees, averaging one hundred feet in height: the Pará species, however, yields the greatest abundance of caoutchouc. Europeans first became acquainted with caoutchouc in the early part of last century, and its botanical history was made known by M. de la Condamine in 1736, but it is only within the last forty or fifty years that it has become an important article in our manufactures and commerce. It exists in the tree, in the form of a thin white milk, and is obtained by making incisions in the trunk, from which it exudes and is collected in little earthen vessels, and afterwards converted into the black homogeneous elastic mass, familiar to us as Indian-rubber, by pouring the milk upon moulds, and immediately holding them over the dense smoke caused by burning the nuts of the Urucuri palms (*Attalea excelsa* and *Cocos coronata*) until it is sufficiently hard to bear another coating, when the process is repeated until the requisite thickness is obtained, and the mould is then removed. Formerly, these moulds were always in the form of shoes or bottles, and hence one of the kinds of caoutchouc is known commercially as *bottle-rubber*; but they are now frequently shaped something like battledores for folding linen, only thinner. In 1863, 65,649 cwt. of Caoutchouc were imported into the United Kingdom.

The raw seeds of these trees are poisonous to man and to quadrupeds, but macaws eat them greedily, and they are an excellent bait for fish; long boiling, however, deprives them of their poison, and renders them palatable.

Siphonifers (a word coined from Gr. σίφων, and Lat. fero, *I bear*). A name given by D'Orbigny and Ferussac to an order of Cephalopods, including all those species which have a siphon contained within a polythalamous shell.

Siphonobranchiates (Gr. σίφων, and βράγχια, *gills*). The name of an order of Gastropods, including those in which the branchial cavity terminates in a tube or siphon more or less prolonged, by which the respiratory current of water is received and expelled.

Siphonophores (Gr. σίφων, and φέρω, *I bear*). A name given by Escholtz to an order of Acalephes, to which he refers those species that have no central digestive cavity, but simply isolated tubes.

Siphonostomes (Gr. σίφων, and στόμα, *a mouth*). The name of a family of Crustaceans, comprehending those which have a siphon-shaped mouth for suction. By M. de Blainville the term is applied to those Gastropods which have the opening of the shell prolonged into a siphon.

Siphorhinians (Gr. σίφων, and ῥίς, ῥινός, *a nose*). A name applied to a tribe of swimming birds, including those which have the nostrils prominent and tubular.

Sipuncle. The name of a genus of worms which burrow in the sands of the sea-shore, and are classed with the *Echinoderms* by Cuvier, and with the *Entozoa* by M. de Blainville. They differ from the soft-bodied *Echinoderms* chiefly in the absence of ampulacral pores.

Sir. The term used in England, either out of respect or formality, in addressing any one. More particularly, it is the distinguishing appellation of knights and baronets, to whose Christian names it is prefixed. Since

the sixteenth century, the word *sire* has been used in prose only in addressing sovereign princes.

In the opinion of Professor Max Müller, the title *senior* (Lat. elder) was changed into *seigneur*, *seigneur* into *sieur*, and *sieur* soon dwindled down into *sir*. (*Lectures on the Science of Language*, first series, vi.) If, however, the word be the same as the German Herr, it is akin to the Latin herus, *a master*, the Greek ἥρως, *a hero*, a word which reappears in such names as HERA and HERACLES.

Siraballi. A valuable and fragrant timber of Demerara, supposed to be the produce of a species of *Oreodaphne*.

Siren. The generic name of certain Perennibranchiate reptiles which have only one pair of feet, and retain the external gills; they are peculiar to the southern provinces of the United States.

Sirens. [SEIRENS.]

Sirene. In Acoustics, an instrument for determining the velocity of aërial vibration, corresponding to the different pitches of musical sounds. 'In this elegant instrument the wind of a bellows is emitted through a small aperture, before which revolves a circular disc pierced with a certain number of holes, arranged in a circle concentric with the axis of rotation, exactly equidistant from each other, and of the same size, &c. The orifice through which the air passes is so situated that each of these holes, during the rotation of the disc, shall pass over it, and let through the air; but the disc is made to revolve so near the orifice that in the intervals between the holes it shall act as a cover, and intercept the air. If the holes be placed obliquely, the action of the current of air alone will set the disc in motion: if perpendicular to the surface, the disc must be moved by wheel-work, by means of which its velocity of rotation is easily regulated, and the number of impulses may be exactly counted. The sound produced is clear and sweet, like the human voice. If, instead of a single aperture for transmitting the air, there be several, so disposed in a circle of equal dimensions with that in which the holes of the disc are situated that each shall be opposite one corresponding hole when at rest, these will all form sounds of one pitch, and being heard together will reinforce each other. The sirene sounds equally when plunged in water and fed by a current of that fluid as in air; thus proving that it is the number of impulses only, and nothing depending on the nature of the medium in which the sound is excited, that influences our appreciation of its pitch.' (Sir J. Herschel's 'Treatise on Sound,' *Encyclopædia Metropolitana*.)

The sirene, as thus described, was invented by Baron Cagniard de la Tour. An instrument on the same principle, and for the same purpose, had formerly been devised by Professor Robison; but the construction was much less elegant and commodious. A current of air passing through a pipe was alternately intercepted and permitted to pass by the shutting and opening of a stop-cock.

Sirenia (Gr. Σειρήν). An order of Mammalia in which the teeth are of different kinds, the incisors preceded by milk-teeth, and molars with flattened or ridged crowns, adapted for vegetable food. The nostrils are two, situated at the upper part of the snout; the lips are beset with stiff bristles; the mammæ are pectoral. The Sirenia exist near coasts or ascend large rivers; browsing on fuci, water-plants, or the grass of the shore. The order which includes the dugongs (*Halicore*) and the manatees (*Manatus*) has existed since the miocene period.

Sirius (Gr. Σείριος, called also *Canicula*, or *Canis Candens*, the *Dog-star*). A star of the first magnitude in the constellation of *Canis Major*, or the Great Dog, and the brightest in the heavens. The Egyptians, observing that the Nile begins to swell at a particular rising of this star, paid it divine honours. [PYRAMID.]

Sirocco (Ital.). A soft relaxing wind, chiefly experienced in the south of Italy, Malta, and Sicily. It blows from the south-east or south; and having been heated over the sandy deserts of Libya, it becomes occasionally moist in its passage across the Mediterranean, and oppresses the inhabitants of the above-named countries with excessive languor and a sinking of the mental energies. The setting in of the sirocco is followed by a considerable rise of the thermometer, and is attended with a haze which obscures the atmosphere. [SIMOOM.]

Sirvente. In the Literature of the Middle Ages, a species of poem in common use among the TROUBADOURS, usually satirical, and divided into strophes of a peculiar construction.

Sismondine. A foliated variety of Chloritoid of a dark-green colour, found at St. Marcel, in Piedmont. Named after Professor Sismonda.

Sisserskite. A variety of Iridosmine, from Sisseresk, in the Ural.

Sister Keelson. The same as SIDE KEELSON.

Sistrum (Gr. σεῖστρον, from σείειν, *to shake*). A kind of timbrel, which the Egyptian priests of Isis used to shake with their hands at the festivals of that goddess.

Sisyphus (Gr. σίσυφος). In Mythology, a descendant of Æolus. By some he is said to have lived at Ephyra, in the Peloponnesus; while others allege that he was a robber, slain by Theseus. His punishment in Tartarus for his crimes committed on earth consisted in rolling a huge stone to the top of a high hill, which constantly recoiled, and thus rendered his labour incessant. The term Sisyphus is supposed to be a reduplicated form of σοφός, *wise* or *cunning*.

Sitology (Gr. σῖτος, *bread*, and λόγος). *Dietetics*, or the doctrine of aliments.

Sitta (Lat.; Gr. σίττη). The name of a bird in Aristotle, which Gesner determined to be the nuthatch. Linnæus retains the term for the genus of which the nuthatch (*Sitta europæa*, Linn.) is the type.

Sium (Gr. σίον, perhaps akin to Celt. siu, *water*). A genus of *Umbelliferæ*, consisting of strong-smelling weedy-looking plants, one of which is grown for culinary purposes, namely *S. Sisarum*, better known by its common name of Skirret. This plant, although usually treated as an annual, is a hardy perennial, a native of China, and has been cultivated in this country since 1548. The roots, for which this plant is cultivated, are composed of small fleshy tubers about the size of the little finger, joined together at the crown. When boiled and served with butter, they form a nice dish, declared by Worlidge, when writing in 1682, to be 'the sweetest, whitest, and most pleasant of roots.'

Siva. In Hindu Mythology, a title given to the Supreme Being, considered in the character of the avenger or destroyer. Sir William Jones has compared Siva to Jupiter; but he appears to share many of the attributes of Pluto. Under the name of Mahadeva, he is exhibited also as a type of reproduction: to destroy, according to the Vedantas of India, the Sufis of Persia, and even to many European schools of philosophy, being only to generate or reproduce under another form. [BRAHMA; MAHADEVA; VISHNU.]

Sivatherium. The name of an extinct genus of Ruminantia found in fossil remains in the tertiary strata of the Sivalik Sub-Himalayan range. It surpassed all known ruminants in size, and had four horns.

Six Clerks in Chancery. Officers who formerly received and filed proceedings, &c. The office was abolished by stat. 5 & 6 Vict. c. 103.

Six-points Circle. [CIRCLE, SIX-POINTS.]

Sixteenmo or **Sextodecimo.** In Printing, a sheet folded into sixteen leaves, or thirty-two pages, is thus termed. It is abbreviated 16mo.

Sizars. The lowest class of students at Cambridge. They have certain allowances made in their battels (college bills), through the benefactions of founders or other charitable persons. In college phraseology, a *size* is a portion of bread, meat, &c., allotted to a student; and hence the name *sizar*. [SERVITOR.]

Size (Span. sisa). A sort of varnish, paint, or glue, used by painters, and in many other trades. It is made of the shreds and parings of leather, parchment, or vellum, boiled in water and strained.

Skeet. On Shipboard, a scoop used for throwing water on the decks and lower sails.

Skeleton (Gr. τὸ σκελετόν, sc. σῶμα, *the dried body*). The desiccated support or framework of an animal body, which, usually consisting of different parts, may be joined together by the dried natural ligaments, is termed *a natural skeleton*; or may be articulated artificially, when it is termed *an artificial skeleton*. In the lowest organised animals, as the *Polygastria* and *Polypi*, the skeleton, when it exists, commonly consists of a single piece. In the *Polygastria* it is external, in the form of a case, and consists of pure silex. In the *Polypi* it is sometimes external, sometimes internal; and is composed of either pure carbonate of lime, or with a small additional proportion of phosphate of lime, these earths being combined with a greater or less proportion of gelatinous animal matter. In the *Isis* the skeleton consists of numerous separate calcareous joints, connected together by portions of uncalcified gelatine. In many of the Lithophytous *Polypes* innumerable minute spiculæ, of various but definite forms, are scattered through the fleshy investment of the main internal skeleton. In the *Echinoderms* the skeleton is external, as regards the viscera; but it is covered by an organised skin. It is remarkable chiefly for the great number of pieces of which it is composed, and the regular and beautiful forms in which they are combined. It likewise supports numerous tubercles or spines, and is composed of carbonate and phosphate of lime, with a gelatinous basis. In *Insects* the skeleton is partly internal, but chiefly external; and its hardening material is a peculiar animal principle, called *chitine*. In cabinets of dried insects it is the natural skeleton that is preserved. In *Crustacea* the skeleton, which bears the same relative position to the animal as in insects, is rendered denser and more brittle by being consolidated with the carbonate and phosphate of lime. In the *Mollusca* the skeleton is generally external, but sometimes internal; it is hardened by the carbonate of lime, with a very slight trace of the phosphate of lime, and constitutes the shell. The beauty, durability, and variety of form of this modification of the skeleton, have rendered the shells of the *Mollusca* at all times a favourite object of collectors, and the subject of a distinct branch of natural history, under the name of CONCHOLOGY. The skeleton of molluscs is either in one piece, as in the univalve molluscs, or in two pieces, as in most bivalves; or in many pieces, as in the multivalve chitons, and others. In the *Cephalopods*, besides the shell, which offers remarkable varieties of form and substance, there is likewise a rudiment of true internal skeleton in a cartilaginous condition. In the Vertebrate animals, there is always an internal skeleton destined to protect the central part of the nervous system, and to form the fulcrum and support of the locomotive members. In a few fishes it is cartilaginous; in the rest of the Vertebrates it is osseous, or consolidated by a large proportion of phosphate and a small proportion of carbonate of lime, and some other hardening salts. [BONE.] This is termed the *endo-skeleton*. In most fishes, in several reptiles, as the crocodilians, and in the armadillos amongst the Mammalia, osseous plates are developed in the substance of the skin; these are analogous to the skeleton of most of the Invertebrate animals, and form a more or less complete protecting case, called the *exo-skeleton*.

Sketch (Ger. skizze, Fr. esquisse). In

Painting, the first delineated idea of the artist's conception of a subject.

Sketching, Military. [FIELD SKETCHING.]

Skew Bridge. A species of bridge in which a road or railway instead of being carried over an opening at right angles with it, is carried over at some other angle, so as better to maintain the continuity of the appointed general track. In skew bridges built of stone, the joints should be spiral. There is an old skew arch at Oxford, built by William of Wykeham. Those who desire practical information about skew bridges may consult the works of Mr. Buck and Mr. Hart.

Skew Determinant. A determinant in which the conjugate constituents are equal in magnitude, but opposite in sign. Conjugate constituents, it will be remembered, are those which are symmetrically placed with respect to the principal diagonal, so that if, generally, $a_{i,k}$ denote the k^{th} constituent on the i^{th} line of a skew determinant of the n^{th} order, we shall have, for all *unequal* values of i and k, $a_{i,k}+a_{k,i}=0$.

Skew Helicoid, commonly called **Screw Surface.** [HELICOID.]

Skew Quadric. A skew surface of the second order. There are two such surfaces: the Hyperboloid of one sheet, and the Hyperbolic Paraboloid. [QUADRIC.]

Skew Surface. A ruled surface of which two successive generators do not in general intersect. The most familiar examples are the hyperboloid of one sheet and the hyperbolic paraboloid; the first generated by the motion of a line which rests on three straight lines [RULED SURFACE], and the other generated by a line which rests on two straight lines and remains parallel to a plane. [CONOID; HELICOID.] The tangent plane at any point of a skew surface contains the generator through that point, which generator is one of the inflexional tangents; conversely, every plane through a generator touches the surface at the point where this generator is intersected by the line joining the intersections of the plane with the next two generators; this latter line is the second inflexional tangent. The hyperboloid generated by a line resting on three consecutive generators of a skew surface [RULED SURFACE], touches the latter along the whole length of one of these generators. The tangent planes through a generator obviously correspond anharmonically with their respective points of contact. [HOMOGRAPHIC.] The points of contact a and a' of pairs of rectangular planes A and A′, through the same generator form a system in involution, the centre of which is the point o *nearest* to the next succeeding generator; for the two inflexional tangents at that point are perpendicular to one another, and the normal plane at o through the generator is parallel to the next generator, and consequently touches the surface at infinity. The point o, therefore, is on the *line of striction*, and the points a and a' on any generator at which a given plane, through the latter, is tangential and normal, respectively, are so distributed that $oa.oa'=$ const. Since the normal planes which pass through the generator correspond anharmonically to the points a at which they are normal, the normals themselves will generate a hyperbolic paraboloid, having the generator itself for a line of striction. The *order* of a skew surface being equal to the number of generators which meets any line, is also equal to its class, since every plane through the line and a generator is a tangent plane. The polar reciprocal of a skew surface, therefore, is another skew surface of the same order. Every plane through a generator of a skew surface of the n^{th} order meets the surface, of course, in a curve consisting of that generator, and a curve of the $(n-1)^{th}$ order; the latter meets the generator in $n-1$ points, one of which will obviously be the point of contact of the plane of the section, and will vary as that plane rotates around the generator; the other $n-2$ will remain fixed during this rotation, and, being points where the generator is met by other generators, will be points of a *double* or *nodal curve* on the skew surface. In general, therefore, we may say that a skew surface of the n^{th} order has, on its surface, a double curve, which is met by each generator in $n-2$ points. Every skew surface satisfies a partial differential equation of the third order, which may be obtained by expressing the condition that the tangent planes at three consecutive points of a generator all pass through the latter. The method of obtaining this equation is explained in all good text-books.

Skew Symmetrical Determinant. A skew determinant whose principal constituents vanish. If $a_{i,k}$ denote, generally, the k^{th} constituent of the i^{th} line of such a determinant S of the n^{th} order, then for *all* values of i and k we have the relation $a_{i,k}+a_{k,i}=0$, which of course implies the vanishing of every principal constituent such as $a_{i,i}$. Since the multiplication of every constituent of S by the factor -1 is equivalent, on the one hand, to the multiplication of the whole determinant by $(-1)^n$, and, on the other hand, in virtue of the above relation to the mere substitution of rows for columns we have the relation $S=(-1)^nS$ [DETERMINANTS]; from this it follows that every skew symmetrical determinant of *odd* order vanishes identically. By equally simple reasoning it can also be proved that every skew symmetrical determinant of *even* order is an exact square. Its root consisting of $(n-1)\ (n-3)\ .\ .\ .\ 3.1$ terms, with $\frac{n}{2}$ factors in each term, is called a PFAFFIAN. Thus

$$\begin{vmatrix} o, & a, & -b, & c \\ -a, & o, & f, & e \\ b, & -f, & o, & d \\ -c, & -e, & -d, & o \end{vmatrix} = (ad+be+cf)^2$$

Further, if $a'_{i,k}$ represent the coefficient of

$a_{i,k}$ in S; i.e. if $a'_{i,k}$ be a first minor of S, and therefore a constituent of the determinant S' of the reciprocal system, then $a'_{i,k} = (-1)^{n-1} a'_{k,i}$; so that S' is symmetrical when n, the order of S, is odd, and skew symmetrical when n is even.

Skewback. In Architecture, the sloping abutment, in brickwork and masonry, for the ends of the arched head of an aperture.

Skid (akin to Ger. scheiden, *to cleave*). A square piece of timber of some length. Also an iron shoe for checking the revolution of a wheel.

SKID. In a ship, any beam or timber used as a support for some heavy body to prevent its weight falling on a weak part of the vessel's structure.

Skid-beams. Timbers laid across the waist of a ship to support the larger boats, especially the launch.

Skiff (another form of the word SHIP). A small light boat, propelled by one man with a pair of sculls, but not of any special build.

Skimmia (Japanese skimmi). A genus of remarkably ornamental evergreen shrubs, with oblong entire leathery dotted leaves, and flowers in terminal panicles, succeeded by bright red drupe-like berries. *S. japonica* is a pretty dwarf-growing holly-like shrub, with dark shining entire leaves and clusters of bright red berries, which give the plant a very handsome appearance. It is now commonly cultivated. The genus is referred by the latest authorities to *Rutaceæ*, but it has considerable affinity with the Orange family.

Skin. The external covering of the body. It is divisible into three parts or membranes. The exterior is called the *scarfskin* or *cuticle*: it is an albuminous membrane. Immediately underneath it is a thin layer of soft or pulpy matter, called *rete mucosum* (mucous network), which is the seat of colour: it lies upon the *cutis*, or true skin, which is a gelatinous texture.

Skink (A.-Sax. scenc). A genus of Lizards in which the legs are dwarfed and in some species almost altogether suppressed, and the tail attains great length.

Skip (Fr. esquiver). In Music, a passage from one sound to another by more than a degree at one time.

Skipper (Dan. from skiff and ship). A name applied to the masters of merchant vessels.

Skirmish (Fr. escarmouche, Ital. scaramuccia). A desultory engagement between troops not in compact bodies.

Skirting. In Architecture, the narrow vertical board on the floor round the sides of an apartment.

Skögbolite. A name proposed for the Tantalite from Skögbole, and Härkäsaari in Finland.

Skolezite. [SCOLEZITE.]

Skolopsite. A silicate of alumina, lime, soda, and other bases, considered by Rammelsberg to be analogous to Sodalite, Nosean, &c. It forms a crystalline granular mixture with a dark-green Pyroxene, in the dolerite of the Kaiserstuhl in Breisgau.

Skorodite. [SCORODITE.]

Skorzite. A Mineralogical synonym of a variety of Epidote, from Skorza.

Skull (Dan. skal, Dutch scheel). The term applied by osteologists to the bony case formed of the coalesced arches of the four peripheral vertebræ of the spinal axis. It is formed of four segments; the occipital, being the epencephalic and the scapular arches; the parietal, being the mesencephalic and the hyoid arches; the frontal, being the prosencephalic and the mandibular; and the nasal, being the rhinencephalic and maxillary arches. This assemblage of vertebræ is connected with the spinal series by two condyles (the neural elements of the occipital bone) or exoccipitals, articulating with the atlas, or first cervical vertebra, which rotates upon the axis.

Skunk. A plantigrade carnivorous mammal (*Mephitis*) found in the New World, where eighteen species are known, eight of which are found in North America, and ten in South America. The genus is specially distinguished by its exceedingly large anal gland, which exhales a putrid and offensive odour, shed by the animal when annoyed or irritated. The scent is so powerful, that it endures for many years.

Skunkweed. The name of the curious stinking North American *Symplocarpus fœtidus*.

Skutterudite. The native arsenide of cobalt found at Skutterud, near Modum, in Norway. It occurs both crystallised and massive, of a colour between tin-white and lead-grey, with a metallic lustre and occasionally an iridescent tarnish.

Sky, Colour of. Various hypotheses have at different times been suggested to account for the blue colour of the sky. Some, with Newton at their head, attribute it to very fine aqueous particles of such thickness as to cause the interference of the yellow waves of white light, thus leaving unneutralised the complementary blue waves. [INTERFERENCE.] Clausius believes, that to procure such an effect the little particles of water must not be little globes, but hollow spheres or vesicles. Others attribute the phenomenon to the greenish blue colour which aqueous vapour, like liquid water, probably possesses; but the blue of water is very different in tint from that of the sky on a bright clear day; moreover, even when the air is very moist it would require the light to pass through a stratum of about 200 miles thick to produce by absorption the green-blue tint observed on looking at a white object through a stratum of water 15 feet thick. The peculiar greenish hue which the sky sometimes assumes in wet weather near the horizon may, however, be due to this cause. Hitherto the blue colour of the sky cannot be said to have received a satisfactory explanation.

Sky Rocket. [ROCKET.]

Sky Sail. A small sail set, on rare occa-

sions and in very light winds, above the royal, on a pole temporarily hoisted for the purpose.

Skylark. The name of a species of the genus ALAUDA; the *Alauda arvensis* of Linnæus.

Slab (Welsh yslab). The name given to large solid and massive slates obtained from the quarry for special purposes. A slab measuring twenty feet by ten and several of somewhat smaller size were exhibited at the International Exhibition in 1862, by the Llangollen Slate Company. They were among the finest and largest ever quarried. [SLATE.]

Slab Line. A small rope leading through a block under the lower yards, and thence to either foot of the sail for the purpose of *tricing* it up.

Slack. Small coal under the size of an egg.

Slag (Dan. slagg). The imperfect glassy or vitrifiable compounds which are produced during the reduction of metallic ores by various fluxes. In the neighbourhood of large smelting works, especially of iron and copper, the slags, which are abundantly produced, are sometimes used as building materials, and for making and mending roads. They often contain a considerable relative proportion of metal.

Slander (Fr. esclandre). In Law, a malicious defamation of a man by words spoken. It is not actionable unless it impute some crime punishable by law; or some contagious disease, which may have the effect of excluding from society the person slandered; or be uttered concerning him in his trade or business in such a way as to impair his means of livelihood; or, lastly, unless it be attended with special damage. A defendant cannot be proceeded against criminally for words spoken, unless they have a direct tendency to a breach of the peace, as by containing a challenge to fight; or are of a seditious or grossly immoral character; or are spoken of a magistrate in the execution of his duty.

Slate or **Clay Slate** (Swed. slita). In Geology, the name given to a very remarkable form of clay rock, frequently fossiliferous and not confined to one geological period. Consisting essentially of clay, the particles of slate are so mechanically arranged, that the rock splits with perfect facility into almost indefinitely thin layers in one direction only, and in all others either breaks with a jagged edge, or in well-defined joints at some distance from each other.

Mineralogically, slate is nothing more than a pure clay; nor does there seem any reason to suppose that any approach is made in it towards crystalline structure. As, however, no other rock shows this tendency to split indefinitely, the case is one of great interest.

Practically, slate is very valuable, owing to its peculiar facility of splitting, and the perfectly smooth natural face which it presents. Its hardness and compactness preserve it from all weathering by mere exposure, though, when ground down, it easily passes back into fine clay.

Slate is always, and properly, regarded as a metamorphic rock. It has certainly undergone much change, though it is not quite certain what the change may have been. In many parts of it crystals of iron pyrites, and sometimes strings and veins of copper pyrites, occur; gold is not unknown in it, and magnetic and other oxides of iron have been found in it. Crystalline garnets are also found occasionally, and curious nodular masses of minerals are segregated into irregular spaces formed in its substance.

The most reasonable explanation of the condition of slate is, that it has undergone enormous squeezing, and that as this squeezing has acted on a rock of which the particles readily adapt themselves without fracture to any required shape, they have been brought into this curious parallel arrangement. The condition of the fossils fully supports this view, as they are almost always squeezed and distorted. A careful examination of the microscopic structure also yields evidence of the same kind.

Slates are not very common. The British Islands are, however, so rich in different varieties, that all in this country are familiar with them. Cornwall, Wales, Scotland, and Ireland all afford quarries of great magnitude, the profits of working which are among the largest obtained in mineral works, in comparison with the amount of capital invested.

The quantity of slates used is very large: at least fifty thousand tons are consumed annually in London alone, although in that city, for local reasons, the houses are generally roofed with tiles. Slates are largely consumed by almost every town and village in the kingdom. More than two-thirds the quantity of slates raised are used for roofing. For this purpose the slates are cut into sizes varying from a few square inches to two square feet, though some are much larger. This is done with very simple tools and extreme rapidity. The rest is in slabs or thick slates, often very large. [SLAB.]

The use of slate and slabs has increased enormously of late years, and is still increasing. Slabs are now used largely in house fittings; as in strong rooms, powder magazines, larders, partitions, baths, stables, floors, drains, &c. For all these, and many like purposes, its perfect resistance to the atmosphere, to all chemical influences, and to the passage of heat, render it invaluable. It has been very largely used also for enamelling; the surface of enamelled slate being made to represent marble of all kinds with wonderful accuracy, and resisting almost all wear. Thus, for mantelpieces, billiard tables, ornamental slabs, and furniture, it has no equal, its cheapness being such as to drive other material out of the market.

The dimensions of the larger quarries, and the number of hands employed in them, render slate one of the most interesting and important of all mineral manufactures.

Many excellent slates are obtained abroad.

Those from the Ardennes, from Angers on the Loire, and from Nassau, are largely exported.

Slate Coal. Coal with a slaty structure, and an uneven and small-grained fracture. The rich caking coal of Newcastle is referred to this variety; as is also the greater part of the coal of the Coalbrook Dale coalfield in Shropshire.

Slate Spar. A massive variety of carbonate of lime, of a shining, white, pearly lustre, and often with a greasy feel; found at Wicklow, in Ireland; Strontian and Glen Tilt, in Scotland; Botallack, and other Cornish mines; at Polgooth mine in Devonshire, and at Coniston in Lancashire; also in Norway and Saxony.

Slave Trade. This term generally denotes the trade in slaves carried on by European nations between the western coasts of Africa and the American settlements.

The European slave trade is generally supposed to have been commenced by the Portuguese about the end of the fifteenth century. About 1508, the Spaniards began to import negroes into America, to supply the place of the Indians, whose numbers were rapidly diminishing under the severity of the toil to which they were exposed by their conquerors. Sir John Hawkins, one of Queen Elizabeth's most famous captains, seems to have been the first Englishman of note who embarked in this traffic, having been concerned in the sale of negroes to the Spaniards in the West Indies. In the same reign the African Company was first chartered, for the purpose of trade with Guinea. This company carried on a trade in negroes with the English settlements in America from the beginning of the seventeenth century to the year 1732. From this period that traffic was carried on chiefly by private traders. It was not until the latter end of the eighteenth century that the atrocities of this trade began to engage the attention of parliament. In 1788, an Act was passed to regulate it; and after twenty years' animated discussion it was at last totally abolished in 1807. The United States of America and Denmark had preceded us in this righteous act. (Clarkson's *History of the Abolition of the Slave Trade.*)

The slave trade is now prohibited by the laws of most European nations except Portugal; and by the law of that country it can be carried on only within certain geographical limits. Nevertheless, it is still followed to some extent by contraband dealers. According to some estimates, about 75,000 slaves are supposed to be annually carried from their homes in Africa to supply the American markets, including those who perish by the way. There can, however, be no doubt that this estimate is very greatly exaggerated; and it may be doubted whether, taking those exported from the east coast to Arabia, &c., into account, the average number of slaves carried from Africa during the ten years ending with 1850 can have been as high as 40,000 a year; since that time even this exportation has probably been materially reduced. The principal importing countries are Cuba, Porto Rico, and Brazil. Publications on the slave trade are so numerous, that it is difficult to make a selection for purposes of reference. Perhaps (after Clarkson's *History*) the student could not find the account of its progress better given than in successive numbers of the *Edinburgh Review*, especially vols. xxi. xxiii. xxiv. xxxvi. cix. cxv.

Slave Trading or **Slave Dealing.** In Law, slave trading, on the high seas, accompanied by a forcible carrying away of the slave, was made piracy, felony, and robbery, by 5 Geo. IV. c. 113, s. 9. And by s. 16 of the same statute a number of other acts relating to and in furtherance of dealing in slaves are made felonious. This is one of those offences of which British law takes cognisance if committed by British subjects in regions out of British dominion.

Slavery. In Moral Philosophy. This term, denoting a state of absolute bondage or total loss of liberty, owes its origin to the vast numbers of Slavonic captives with which Spain became filled during the wars of the Frank kings; and thus a national designation, meaning in its own tongue *glorious*, became the common title of servitude. (Freeman, *History and Conquests of the Saracens*, 195; Gibbon, *Roman Empire*, ch. lv.) But the condition of slavery has been found originally in all countries, and subsists to this day over the larger portion of the earth. The liberty of the ancient world, whether at Athens or elsewhere, was only the freedom of a class, and in the states which were most free implied, perhaps, most of all the existence of a class of men who were not free. [PRIMARY ASSEMBLIES; LIBERTY.] 'We lose a good deal of our sympathy with the spirit of freedom in Greece and Rome, when the importunate recollection occurs to us of the tasks which might be enjoined, and the punishments which might be inflicted, without control either of law or opinion, by the keenest patriot of the Comitia, or the Council of Five Thousand.' (Hallam, *Middle Ages*, ch. ii. part ii.)

According to Aristotle (*Polit.* i. 1), the distinction between despot and slave was as strictly a distinction of nature as that between male and female. Nothing can be clearer than the language in which he asserts that slaves and women are destitute of the natural capacity for government, this capacity being dependent altogether on intellectual foresight, in which they have no share. Hence the great body of slaves, and the great body of masters or despots, form each a distinct whole, set by nature one against the other, ἓν πρὸς ἕν. Hence the slave was merely an animated machine, κτῆμά τι ἔμψυχον, and such he must continue, as much as a woman must remain a woman. This distinction was, however, rather the theoretical than the practical foundation of Greek or other ancient slavery, and Aristotle is obliged to allow (*Polit.* i. 6. 1) that the word δουλεία, *slavery*, is susceptible of more than one meaning, and that war and other causes were constantly reducing into the ranks of slavery

those who had been born free, and who may have risen to the highest distinction as statesmen and philosophers. On this subject, which involves the most horrible aspect of all ancient civilisation, Aristotle can only multiply sophistical quibbles. It is a legal principle, he tells us, that things taken in war shall be in the power of the taker, and all men taken in war are things; and at all events, whatever be the justice of the principle, he finds some comfort in thinking that superiority of force, which is implied in the idea of victory, implies also a greater excellence or virtue (ἀρετή) in the conqueror than in the conquered. This theory acted necessarily with great force on the Greek and Roman feeling of patriotism. Underneath its apparently exalted character lurked an intense selfishness; the struggle was for something of which at any moment the citizen might be himself deprived, and of which he was quite ready to deprive others; and thus, in the words of Macaulay (*Essays*, Machiavelli), patriotism became with them a governing principle, or rather an ungovernable passion.

The Aristotelian argument, grounded on natural distinctions, is as an argument beneath contempt, and could have been maintained only by those who were obstinately bent on holding their position, whether logically tenable or not. The necessary result of a natural distinction is, that it is accepted as unalterable, and acquiesced in. Individual women may be found to express discontent at certain circumstances in their condition; but no course of action has ever been taken by bodies of women for the express purpose of abolishing the natural distinction which marks their sex. Natural distinctions, again, admit of no exception; all women know themselves to be women, and the occurrence of individuals who could not be classed in the natural order of men or women would upset the natural distinction. In both these points, the theory of Aristotle breaks down. The slaves have not universally acquiesced in their condition; and among slaves many have not exhibited the marks which Aristotle asserts to be essential to a slave. The whole history of the ancient world attests a general fear of the slaves on the part of their masters, and a constant readiness on the part of the slave to rebel against his masters. Whatever may have been the nature of the Spartan CRYPTEIA, we have undoubted historical evidence which proves that the Spartans could by a pretended gift of freedom entrap hundreds of men, whose bravery they dreaded, into a destruction, accomplished no one ever knew how. In Italy the discontent of the slaves broke out from time to time into formidable rebellions and wars; and the whole Roman law of slavery implied an utter distrust of the fancied natural distinction on which Aristotle grounded the justice of the system, for with him slavery was not an institution, but a necessary phase of human nature. The execution of the whole familia of Pedanius, 400 in number, by order of the senate in the time of Nero, because one slave, being refused his liberty, had slain his master, is but one example of a method of treatment which took for granted that the slaves did not and could not acquiesce in their position as an ordinance of nature.

There were other circumstances under which the theory of Aristotle became not only contemptible but ridiculous. The essence of his definition of slavery is that the foresight of the slave is simply that of the mole or the beaver. His masters have intellectual power (διάνοια); he has only a bodily instinct (προορᾶν σώματι); but as he has only this, it is as impossible for him to rise to anything higher, as it is for an elephant or a monkey to take part in the debates in the House of Commons. Yet, under pressure in time of war, Athenian masters were ready enough to enfranchise all slaves fit for bearing arms; and thus to let loose upon society beings who, according to the Aristotelian theory, were simply able-bodied bears or wolves. (Grote, *History of Greece*, part ii. ch. xc. vol. x. p. 694.)

If, again, the idea of a class of natural slaves is set aside by the appearance, among slaves, of individuals endowed with high intellectual powers, the idea of a class of natural rulers is also upset by the appearance, in oligarchic or aristocratic bodies, of persons of debased minds and slavish wills; and, whatever may be said of the latter, it becomes sheer injustice if the former be condemned to a life of slavery. Hence, Aristotle strove hard to prove that nature made the bodies of slaves different from the bodies of natural rulers, and doubtless shut his eyes to slavish bodies which he saw from time to time whether in the Macedonian court or in the houses of Athenian citizens.

At Athens, therefore, or in Rome, the treatment of the slave depended almost entirely on the will and disposition of the master; and the rules given in the so-called Aristotelian *Œconomics* (i. 5) are addressed simply to the self-interest of the owner, and not grounded on any legal, far less on any moral, rights of the slave. For a slavery more merciful in theory, and probably far less hateful in practice, we must look neither to Greeks nor Romans, but to the Jews, whose system, as depicted in the Pentateuch, contrasts most favourably with the slavery not only of the Turks, but with that more horrible form of bondage which prevailed in our West Indian colonies, and was maintained to a later time by the Southern States of the American Union. In his *Treatise on American Slavery*, Professor Goldwin Smith has shown that the Mosaic legislation recognised a common bond of interest between master and bondman, and threw over the latter the protection of the law; that it made no distinction between his testimony and that of the freeman; that it sanctioned his marriage, and recognised his family, while it united the slave and his master in every act of religious worship, and upheld the honourable character of manual labour. He has further shown that the American slave system cannot exist without a fugitive slave law, while the

Mosaic legislation bids the Jews rather to run the risk of war than to give up the runaway slave. In the Mosaic, and even in the Turkish system, the child follows the condition of the father; it was reserved for slave-owners calling themselves Christians to look on the faces of their children and receive in dollars the recompense for the sale of their own blood. The serfdom introduced by the German tribes differed from the slavery of the ancient world only, perhaps, in the obligation which tied the villein to the estate of his lord. (Hallam, *Middle Ages*, ch. ii. part ii.) [SERF; VILLEIN.]

In the civilisation of modern Europe, slavery, having passed through the phase of serfdom, has been gradually weakened and abolished. But 'the great change in the condition of the servile order arose chiefly from other causes, besides the influence of Christianity.' (Milman, *Latin Christianity*, book iii. ch. v.) Asserting that the influence of Christianity must have tended from the first to mitigate the horrors of slavery, Dean Milman thinks that in the later Roman empire it was rather the multiplication of slaves which slowly wrought its own remedy. It is quite certain that the Christian Church did not from the first enter the lists against the principle of slavery. 'The Churches themselves were slave-holders; there were special provisions to defend their slaves,' and, by some Teutonic codes, whoever concealed the slave of an ecclesiastic was condemned to a triple fine. The laws of Justinian not only recognise slavery as a permanent institution, but 'ascribe to the heathen sovereign Antoninus, the great change which had placed the life of the slave under the protection of the law. . . . But the abrogation of slavery was not contemplated even as a remote possibility. A general enfranchisement seems never to have dawned on the wisest and best of the Christian writers, notwithstanding the greater facilities for manumission and the sanctity, as it were, assigned to the act by Constantine, by placing it under the special superintendence of the clergy.' Even as so amended, the Christian slavery of Justinian was far inferior to the Jewish slavery of the Pentateuch. The testimony of the slave could be received against his master only in cases of high treason, and his union with his wife was still only concubinage, not marriage. 'Basil the Macedonian,' in the ninth century, 'first enacted that the priestly benediction should hallow the marriage of the slave; but the authority of the emperor was counteracted by the deep-rooted prejudices of centuries. It was the weakness of Rome, not her humanity or Christianity, which, by ceasing to supply the markets with hordes of conquered barbarians, diminished the trade' in slaves, and thus hastened the downfall of the institution.

It may further be remarked that the Aristotelian theory of natural distinctions might derive a plausible colour from the notions entertained by some as to the characteristics and destiny of the negro race. But the slaves of the Greeks and Romans (even if we take into no account those who were reduced to slavery by debt or the fortune of war) were of no such alien race, although they may have represented those earlier possessors of the soil who were conquered by the Dorians, Ionians, or Latins. The Jewish slavery was confined to that of bought slaves: no Hebrew could be permanently retained in bondage, and his servitude, as Mr. Goldwin Smith remarks, 'was, in fact, not slavery at all, in the proper sense of the term.' But it is obvious that the theory of a natural distinction like that of Aristotle cannot be maintained, if the supposed servile class has a capacity for amalgamation, and does in fact amalgamate with the ruling class. Among the Greek and Roman bondmen there were many born slaves, whose forefathers had been free citizens, deprived of their freedom for debt. In the English West India islands and in the Southern States of the American Union, a considerable proportion of the children of negro slave women were or are the children of white slave-owners. The idea of a natural distinction is thus summarily rejected even by those who may be most interested in maintaining it.

To slavery in Europe the deathblow was given by the refutation of notions based on an antipathy to labour as contemptible and degrading. The real idea of slavery is that of a large class condemned to servile toil, in order that a narrow class may be altogether idle. Such an idea is antagonistic with the whole spirit of modern European civilisation: and wherever this spirit finds its way, slavery must decline and eventually perish.

For the theories of Bodin and others on slavery, see Hallam, *Literary History*, part ii. ch. iv.; Lecky, *History of Rationalism*, ch. vi.

SLAVERY. In Political Economy. The practices of exacting compulsory labour, and of recognising the right on the part of some members of society to hold others to involuntary bondage, are found universally in the customs and laws of both ancient and modern communities. Labour is a condition of existence, but it is on the whole disliked, shortened, and as far as possible avoided, either by laying it on others than those who reap its advantages, or by employing natural forces in lieu of muscular exertion. Such natural forces can be used very scantily in the early stages of social developement; and slavery, the easier and more obvious means for avoiding labour, is thus generally practised in primitive, uncivilised, or imperfectly civilised communities. But we shall see that the adoption of this alternative as a means for economising or avoiding labour, is the most permanent among the hindrances to any real progress in those mechanical arts which tend to shorten human labour, and thus put the largest amount of conveniences at the least possible cost within the reach of the greatest number of persons. Though the origin of slavery is found in economical influences or motives, the retention of slavery is a permanent impediment to the developement of the best economical state.

Slavery existed in all ancient communities, and in several forms, side by side with great intellectual activity, and with unexampled skill in the fine arts. It is compatible with great progress in the sciences of law and government. But the mechanical arts are very scantily developed wherever slavery exists, even in its modified forms; and even when these arts have been partially discovered, their growth has been arrested, or their application dwarfed, by its pressure. The ancient world was almost entirely ignorant of the inductive sciences, though the passion for physical study and research was very keen, and the advantage of possessing these sciences as the means of economy within the state, and of protection from external aggression, was obvious. The cause of this imperfect growth is to be found in the prevalence of slavery.

Slavery arose historically, as far as can be traced, from war, from piracy—if indeed the two can be distinguished in early times—and from the penalties levied on offenders against persons and property. As, according to the original theory, the life as well as the fortunes of the vanquished are at the discretion of the conqueror, slavery was at its beginning a humane or merciful substitute for the exercise of these extreme rights, like the ransom which the captor exacted from his prisoners in the middle ages. So, again, the slave market of the ancient world was supplied (in default of captives taken in war) by descents on the coasts of foreign races, and probably also by the purchase of foreign captives, whom their captors disposed of to the Greek, Carthaginian, or Asiatic merchant. Sometimes, especially in the eastern world, the tribute of a conquered region was expressly defined by the supply of a certain number of male and female slaves. Again, in early systems of jurisprudence, laws are intended rather to protect individuals, and to recompense individual wrongs, than to vindicate or secure the well-being of society. The latter object of judicial procedure was too refined and abstract to be comprehended in these early ages. It would not have suited the notions of justice which prevailed in communities, among whom public ties were slight, and intense only under particular emergencies. And even when the doctrine of obligation to a central authority, and the vindication of injuries against the constitution or the vitality of society were recognised, the means adopted were rather a control over the acts, lives, and customs of men, than a system of punishments which remedied private wrongs only indirectly. Hence, when the judge took cognisance of injuries committed on private persons, his decision generally assumed the form of a fine, or, if the criminal was unable to pay the fine, an adjudication of his person to the injured parties as the fairest and fullest satisfaction which could be made. Such a means of compensation, known in ancient Rome, was exceedingly common among nations of Germanic origin, and in times of violence must have been a frequent cause of slavery.

Again, as debt was treated as a species of civil crime, and as persons in these states of society were permitted to pledge themselves and their families as security for loans contracted, defaulting debtors were, either by the terms of their contract, or by judicial decisions, assigned or adjudged as slaves to their creditors. [SEISACHTHEIA.] The two forms by which such a result occurred in ancient Rome are discussed by Niebuhr and Savigny. A slight trace of this custom in England may perhaps be discovered in those ancient forms of obligation known as STATUTE MERCHANT and STATUTE STAPLE, as the custom of imprisonment for debt was a substitute for personal slavery consequent on an adjudication upon a civil plea and the issue of execution.

Slavery is either absolute or partial, the latter being generally called *serfage*. [SERF.] In the former case, there is a denial of all personal rights, and of all property to the slave. But humanity and policy have rarely permitted this total extinction of all rights in the slave, whenever, at least, the community has stood above the level of the merest barbarism. Thus, in Athens, an ill-used slave could take refuge in the temple of Theseus, and demand that his master should sell him. Assaults on slaves were punishable by indictment, and no slave could be put to death without trial. In Rome, he was permitted the possession of property, under the name of *peculium*; and though the treatment to which he was subject was harsher, it appears, than in Greece, we must take into account, in explanation of this fact, that authority was largely and unsparingly exercised by the Roman husband and father over his wife and children. It cannot be doubted that the comparative lenity with which the slave was treated in the ancient world, must, all circumstances considered, be ascribed to the fact, that many of those unfortunates were of the same or nearly the same origin with their lords, and that the social difference between them was not aggravated by fundamental distinctions of race or colour.

Slavery was virtually extinct throughout European Christendom at the time in which the New World was discovered. It is true that penal servitude of a very severe character still existed in the condemnations to the galleys. But penal servitude stands on a totally different footing from slavery; though, under the form of transportation, its effects on the object of the sentence were to reduce him either permanently or temporarily to the condition of a slave.

The first occupation of the New World was accompanied by the enslaving of its inhabitants, in those regions at least where the Spaniards and Portuguese found an abundant population and a settled government. The natives were constrained to labour in the mines and other kinds of toil, adverted to above, under the title PEONAGE. By these means the population was nearly extirpated. To save

the remainder, the benevolent missionary Las Casas recommended the importation of negroes; the slave trade was commenced on the western coast of Africa, and a large negro population was introduced into the New World. The other European nations followed the example of Spain in all their American colonies, and a slavery of race and colour became general. The traffic in slaves, though atrociously cruel, was exceedingly profitable, and the interest of a large and influential body of merchants was enlisted in the trade. The slaves were collected on the low coast of South-Western Africa at very cheap rates, were stored in stifling vessels, and transported across the Atlantic. The rate of mortality during the passage was enormous, but the price of the slave on the coast amply compensated the loss, even when the per-centage of deaths was exceedingly high. Gradually philanthropists called attention to the traffic, and, in spite of many obstacles, the slave trade was suppressed and treated as piracy, almost all European nations having concurred in the schemes for stopping or at least for checking it. But as these measures were not generally coupled with the emancipation of negroes in the several American governments and colonies, the effect of legally abolishing the slave trade was only that of making the sea passage more difficult, and of raising the price of the slave in the New World.

Slavery was abolished in the British colonies in the year 1834, the owners being compensated by a grant of twenty millions. Several of the northern states in the American Union had, however, decreed the extinction of slavery long before this time. Its final extinction in the Union was the fruit of the late war, as the attempts to extend it on the one side and to limit it on the other were the cause of that gigantic struggle. It still exists in the Spanish dependencies of Cuba and Porto Rico, and in Brazil; but a considerable and increasing party in Spain is pledged to the abolition of slavery in the Spanish colonies.

In general, it may be stated that slavery was exhibited in its harshest and most repulsive features on the American continent. Nothing interfered practically between the will of the master and the sufferings of the slave; for although some laws were enacted for the protection of the slave, evidence that these laws were broken was in any case difficult, and was generally unattainable, since the slave was precluded from being heard in a court of justice. There were no limits to the hours of labour, except the interest of the slave-owner in the slave's life, and this interest was a very weak guarantee against the prospect of immediate gain, or the impulse of uncontrolled passion.

The effect of slavery, and especially of negro slavery, on those communities in which it is encouraged, protected, or permitted, is twofold —moral and economical. It induces habits of lawlessness and licentiousness; the former by the fact that great powers of repression, or at least of independent action, must be accorded to the slave-owner; the latter by the ease and impunity with which passion is gratified. The evidence on the latter head is overwhelming, especially from those who have witnessed the effects of slavery in Brazil.

Its economical effects are numerous. By the degradation necessarily connected with the social position of the slave, labour is disparaged and discredited. The backward state of all slaveholding communities, and (even where they have reached a certain state in wealth) their rapid declension, are notorious facts. Besides, as the capital of the slave-owner is to a great extent invested in his slaves, so the whole weight of bad harvests and adverse markets falls on the owner. Where labour is free, national losses affect, as a rule, all classes equally; where it is compulsory, these losses fall entirely upon capital or profits. Again, there is always, when labour is free, an impulse affecting capitalist and labourer alike, towards shortening or economising labour as fully as possible. The labourer is impelled to get the highest remuneration at the least labour; the capitalist, still more effectually, to achieve the highest price at the least cost. Hence the improvements in machinery, which have characterised the condition of free labour. But in a state of slavery such a disposition to economy would not affect the master, partly because labour by the very existence of slavery is relatively cheap; partly, because compulsory labour cannot be depended on, except for the simplest operations. Still less, however, is the slave disposed to economise his labour by the use of any substitutive instrument, as he has no interest in his own effectiveness. It was from the prevalence of slavery that no progress, or no important progress, was made in the industrial arts among ancient nations. Lastly, as labour is exercised under the most disadvantageous conditions when it is compulsory, so it is most exhausting to the soil. With such a social state, a community needs perpetual additions to its area; and it will be found, whatever be the pursuits of such a community, that it needs a far larger territory to support an equal population than countries of which the soil is free.

Slavonic Languages. A name applied to the dialects of Lithuania, Russia, and Poland, the speech of the Slavonic tribes who began their advance into Mœsia and Thrace in the fifth century, and were settled in Macedonia in the following century. The most ancient document of the Bulgarian and Illyrian, or eastern branch of the Slavonic, is the translation of the Bible made by Cyril and Methodius in the ninth century. [LANGUAGE.]

Sledge (A.-Sax. slecge, Swed. slagga). A vehicle without wheels, used as a means of locomotion on snow. Sledges are used during the winter in Canada and Russia, &c.; but the country with which the name is most associated is Lapland, where two kinds are used; the one being the pulk or close sledge for the use of

travellers and merchants, the head being pointed like a canoe, and the body being covered by an oval half-deck, covered with seal skins. This sledge is generally about seven feet in length, sixteen inches in breadth, and eight inches in depth. For the conveyance of goods a longer sledge is used, which has no deck. A single reindeer will draw a sledge at the rate of ten miles an hour at a trot, and at the rate of twenty miles at a gallop.

Sleep (Ger. schlaf). That state of the body in which the functions of sensation and volition are suspended, while the vital functions retain their usual activity: the operations of the mind, if not at perfect rest, being disconnected with external objects.

Healthy or natural sleep usually comes on with a peculiar sense of muscular lassitude, gaping, and desire of repose; the eyelids fall, and there is general muscular relaxation. The sense of hearing is that which is longest retained; and we generally hear what is going on about us, and even feel inclined to take occasional part in conversation, long after the eyes are closed.

The quantity of sleep required by different individuals is various, from six to nine hours being the average proportion. Indolent listless persons, and especially those who indulge in the luxuries of the table, and are in good health, will often slumber away from eight to ten hours daily; while others of active dispositions, and who live abstemiously, will be satisfied with four or five hours of sleep: and such persons are generally more disturbed by dreams than the former. Very young children sleep away much of their time, and so also do many old persons. Sleep is often prevented by intense thought, by anxiety, and other mental affections; and also by hunger, and by the application of cold to a part of the body. When a person has been over-fatigued by bodily exertion, sleep is also often courted in vain; and there are many stimuli by which its accession at the usual times is prevented or retarded, such as strong tea, coffee, small doses of opium, and several other articles of medicine and diet. Bodily exercise and mental tranquillity, a full meal, the absence of light, noise, and other disturbing causes, are circumstances generally favourable to sleep; but in all these respects various habits often greatly interfere, and persons accustomed to very active lives when suddenly deprived of their usual occupations often sleep worse than before, indolence becoming an apparent stimulant.

The definition of sleep is still a subject of controversy, some maintaining that we are conscious, others that we are unconscious, while we sleep; while by some it is held that dreams occur during sleep, by others that they occur only between sleeping and waking, i.e. during imperfect sleep. In his treatise *On Sleep*, Sir Henry Holland asserts that 'sleep, in the most general and correct sense of the term, must be regarded not as one single state, but a succession of states in constant variation, this variation consisting not only in the different degrees in which the same sense or faculty is submitted to it, but also in the different proportions in which these several powers are under its influence at the same time.' In his *Physiology of Sleep*, Mr. Arthur Durham says that 'sleep, considered psychologically, may best be defined to be a state in which volition, sensation, and consciousness, are suspended, but can be readily restored on the application of some stimulus.' Considered physiologically, sleep, he thinks, 'may be most correctly regarded as that particular state of cerebral activity, which is essentially associated with the nutrition and repair of the brain substance.' These definitions may appear at first sight opposed to each other, but they may probably be reconciled by the hypothesis that Sir Henry Holland is speaking of actual sleep, while Mr. Durham gives a definition of typical or perfect sleep. Indeed, the conclusions of the latter writer are supported by a series of experiments on the brain of living animals, which seem to establish conclusively the position of Sir H. Holland, that sleep, as it actually occurs in men and other animals, is a succession of ever-varying states.

If sleep be, as undoubtedly it is, a state necessary for the repair of the waste caused by activity of the brain during the hours of wakefulness, the essential conditions of the latter state, when perfect, may be defined to be 'functional activity of the brain, as manifested by sense and intellect, together with destruction of brain substance,' while the corresponding conditions of perfect sleep will be 'rest of the brain (suspension to a greater or less extent of those faculties which are the manifestations of its activity), together with repair and nutrition of brain substance.' Hence, from an anatomical point of view, sleep may be described as 'a state in which the blood-vessels of the brain are occupied by a comparatively small quantity of blood moving at a comparatively slow rate.' That this is actually the case during sleep, all experiments seem conclusively to prove, while they tend further to establish the fact that 'when we are soundly asleep, we do not instantaneously awake to full possession of our faculties; still less do we pass at once from perfect wakefulness into a state of healthy sleep.'

A purely psychological treatment of the subject may be found in M. Alfred Maury's work, *Le Sommeil et les Rêves*. (*Westminster Review*, No. xlix. 'The Physiology of Sleep.')

Sleep-walking. [SOMNAMBULISM.]

Sleeper. In Architecture, a piece of timber whereon are laid the ground joists of a floor. *Sleepers* are also pieces of timber, now rarely used, in foundations, crossed by planks, &c., and at right angles to them, where the soil is bad. Formerly the term was used to denote the valley rafters of a roof.

SLEEPER. [RAILWAYS.]

Sleet (Icelandic sletta, Dan. slud). Snow or hail which is in a partially melted condition

before it reaches the surface of the earth. In some cases sleet may also be produced by the simultaneous precipitation of snow or hail from a superior and of rain from an inferior stratum of the atmosphere. [HAIL; SNOW.]

Sleigh. [SLEDGE.]

Sleight-of-Hand. [CONJURING; LEGERDEMAIN.]

Slewing. In the service of Artillery, turning a gun or mortar on its axis without moving it from the spot on which it rests. The term is also applied to turning a gun or mortar horizontally upon a pivot; this is called *slewing end for end.*

Slices. Wedges of small angle driven immediately before launching under the shores by which the ship is sustained on the shipway. Being driven in simultaneously all round the vessel by blows of hammers, the mass is raised sufficiently to enable the blocks on which the keel has rested to be removed.

Slickenside. A provincial term applied by the Derbyshire miners to Galena or sulphide of lead, which has acquired a smooth and shining striated surface in consequence of the great pressure and friction to which it has been subjected by the dislocation and shifting of the vein. In Geology, the term has a more extended meaning, and is applied to the smooth and polished surfaces which have been produced in any kind of rock by the grinding motion resulting from faults, or fractures and contortions of the beds.

Slide. In Music, a grace used in the German school, and consisting of two small notes moving by degrees.

Slide Rest. A guide employed to carry forward the cutting tool of a turning lathe to the axis of the revolving object. Slide rests of great variety are now used in the arts, and some of them are so contrived as gradually to withdraw the tool as it approaches the middle of the length of the object, so as to turn by self-acting mechanism a rod bulging in the middle.

Slide Valve. A form of valve in which the opening and closing of the orifice is regulated by a sliding plate or plug in the manner of a sluice. One of the earliest examples of the slide valve was the valve of Lavoisier's air-pump, and the slide valve has been applied to feed-pumps, and to pumps of various kinds. Its most common application, however, is to the STEAM ENGINE, to govern the flow of steam to and from the cylinder, its movements being controlled by a moving part of the engine called the *eccentric.*

Sliding Axis. [INSTANTANEOUS SLIDING AXIS.]

Sliding Keel. A narrow oblong board let down at pleasure vertically through the bottom of a small vessel, to serve as a deepening of the keel throughout a portion of her length. Its use is, like that of the leeboard, to sustain the vessel against the lateral force of the wind, and to enable it to bear more sail. At present, the more usual name for this instrument is the *centre-board*, and the boats so fitted are known as *centre-board boats.* The employment of the centre-board is much resorted to in America for small river craft, and in this country for yachts of small burden. It is a great element of safety; and, with its help, boats of draught suited to river navigation may venture into a moderate sea.

Sliding Rule. A mathematical instrument or scale, consisting of two parts, one of which *slides* along the other. As each has certain sets of numbers engraved on it, so arranged that when a given number on the one scale is brought to coincide with a given number on the other, the product or some other function of the two numbers is obtained by inspection. The numbers may be adapted to answer various purposes; but the instrument is chiefly used in gauging, and for the mensuration of timber.

Sliding Scale. In Finance, an attempt to regulate prices by varying the rate of taxation on imports in proportion to the price at which a home produce of the same or a similar kind is offered for sale. Thus, if the soil of a given country grows on ordinary occasions a certain amount of corn, sufficient or nearly sufficient for the subsistence of the people, but which needs for the maintenance of some of its inhabitants, at all times, and in increased quantities in times of scarcity, supplies from foreign countries, the demand for foreign corn will fluctuate according to the exigencies of the market, increasing when the home supply is deficient, decreasing when it is abundant. Now, as the causes which induce a scarcity in one country, even on one kind of soil, are favourable to abundant growth in another country, or even in another kind of soil, the national remedy for occasional dearth in one locality is the compensating plenty of other localities. Such would be, had legislation never interfered with supply and demand in the interest of particular persons, the ordinary course of international trade in agricultural products: and, primâ facie, it would be just as irrational to regulate the corn trade between, say, this country and Russia, as it would be to pass a law, by which a tax should be imposed in wet years on light lands, in the interest of those who grew wheat on heavy soils, or, vice versâ, on heavy lands in dry years, with a view to compensate scanty crops on light soils.

With the purpose, however, of securing a permanent high price for corn, the government of this country proposed, in the year 1814, a sliding scale of charges on which corn could be imported: when the home price was at or under 64*s.* the duty levied was 24*s.*, when at or under 65*s.*, 23*s.*, and so on up till the home price reached 86*s.* at which point the duty was to be 1*s.* This bill failed, but another was brought forward in the following year fixing the maximum at 80*s.*, and, notwithstanding strenuous opposition, the bill passed. Similar Acts, the details of which may be found in Mr. M'Culloch's account of the corn laws and corn trade, printed with the appendix to his edition of Adam Smith, were passed up to the date of their abolition.

The sliding scale totally failed in effecting its purpose. Its adoption was due, it may be asserted, to gross ignorance of the doctrine of prices. The canon now thoroughly understood, but then only imperfectly apprehended, is that the prices of the necessaries of life rise in a geometrical ratio with scarcity, to an unlimited amount, and fall in the same ratio as the occurrence of plenty to a limited amount. There is no check to the exaltation of prices in times of famine, until of course population perishes; but, in times of excessive plenty, the limit, though low, is seldom transgressed, because the agriculturist or corn merchant is impelled to retain his stock in hopes of a better market, and because (to some extent, at least) a period of low prices in the necessaries of life is generally accompanied by an inward demand for what may be called the secondary or subordinate products of agriculture, such as meat, butter, cheese, and the like. Now, as under the operations of the sliding scale, the foreign supply was uncertain, because the demand was excessively fluctuating (though considerable quantities of corn were stored in bond), the price of home produce varied extremely, falling sometimes so low that the farmer, who was forced by this artificial system to depend mainly on wheat prices, was unable to fulfil his obligations to his landlord, and rising sometimes so high as to put the greatest distress on the mass of the people. Further, as soon as the price reached the point at which corn could be imported duty free, the country was flooded with foreign corn, and the reaction was excessive. The sliding scale appeared to confer a boon on the agriculturist; in effect it inflicted a lasting injury, because it increased the range over which prices varied, the worst condition in which producer and consumer could be placed. Nothing was more common, and nothing indeed was more natural, than the complaints of agricultural distress which were uttered during the maintenance of the corn laws and sliding scale—complaints which have been silenced by those measures of reform which landlords and farmers predicted would be their ruin, but which have, on the contrary, been their preservation.

A regulation analogous to a sliding scale is at the present time operative on banking credit. By a series of causes, some of which have arisen naturally, some from legislative arrangement, the issue of paper credit, in the form of Bank notes, is practically confined to one establishment—the bank of England. Under certain circumstances, the demand for banking credit, for the purposes of absolutely legitimate trade, rises and falls considerably; and as this banking credit, in mercantile transactions, is as essential to commercial existence as food is to population, so in times when the demand is excessive any hindrance of supply precipitates and intensifies a period of commercial panic, i.e. a state when paper credit is undoubtedly high, but commercial credit is temporarily low. In this crisis, the Bank Act restricts the issue of paper and thus checks accommodation, operating exactly as the sliding scale did on corn, with this important difference, that as the corn law was relaxed, when famine was imminent, the Bank Act is stringent only when the necessities of the position demand an enlargement of credit.

Sliding Ways. In Shipbuilding, two narrow inclined planes built strongly on the shipway, and intended to form the tracks by which the cradle sustaining the vessel glides into the water.

Sling (Ger. schlinge). A weapon made of a strap and two strings, by means of which a stone or other missile is projected with much greater velocity than could be given to it by the hand without such assistance. The velocity with which the projectile is discharged is the same as that with which it is whirled round in a circle having the string for its radius, and may therefore be computed when the time of revolution and the length of the string are given. The sling was known as a weapon of offence in the earliest ages.

Sling Cart. In the service of Artillery, a two-wheeled carriage for transporting ordnance through short distances. A *sling waggon* has four wheels, and is used for longer distances.

Slings. On Shipboard, combinations of rope for hoisting horses, casks, or goods, in or out of the vessel. Also ropes or chains by which yards are suspended in their places to the relief of the lifts.

Slip. In a dockyard, an inclined plane having an inclination to the horizon of about 1 in 19, laid upon a most solid foundation, and serving as the base on which a ship is built, and from which, by its slope, the vessel is run into the water when finished. Repairing slips are now furnished with carriages on many wheels and rails, which are run under ships as they float at high tide, so that when the ebbing water has grounded the vessels on the trucks, they can be hauled up by steam power high and dry for examination or repairs.

Slip Stoppers. On Shipboard, apparatus for suddenly letting the anchor go out of its lashings and fishings, when it is required to drop it.

Slips. In Printing, where from the nature of the work, great alterations and corrections are made in the proofs, they are occasionally printed on slips of paper. This gives facility to an author or editor to add or take away matter without overrunning or remaking up.

Sloam (probably akin to *loam*, as *slime* to the Latin limus, *mud*). Layers of clay between those of coal.

Sloanea (after Sir Hans Sloane). A tropical American genus of *Tiliaceæ*, consisting of trees often upwards of a hundred feet high, the wood of many of them being extremely hard and difficult to work; that of *S. jamaicensis* is known in Jamaica as Breakaxe and Ironwood.

Sloanite. A hydrated silicate of alumina, lime, and magnesia, found in white radiating masses, in the gabbro rosso of Tuscany. It is named after Mr. Henry Sloane.

Sloe (A.-Sax. sla, Ger. schlehe). The

name of one of our wild Plums, *Prunus spinosa*, remarkable for the austere flavour of its fruit.

Sloke. Another name for Laver, which is prepared from the common *Porphyra vulgaris* and *P. laciniata*. Green Sloke is a name given in Scotland to several species of *Ulva*, which are also called Oystergreen.

Sloop (Dutch sloep, Fr. chaloupe). A vessel with one mast like a cutter; but having a jib stay, which a cutter has not. Also the general name for ships of war below the size of corvettes, and above that of brigs.

Slope. In Geometry, angular departure from a horizontal direction. The *lines of greatest slope* on any surface cut at right angles the *lines of level*. If $u=0$ be the equation to any surface, referred to rectangular co-ordinates, then the plane of (x,y) being horizontal the equations of the projections upon it of the lines of level will be formed by putting $z=c$, a constant, and the differential equation of these lines will be

$$\frac{du}{dx}dx+\frac{du}{dy}dy=0;$$

consequently the differential equation of the projections of the lines of greatest slope will be

$$\frac{du}{dx}dy-\frac{du}{dy}dx=0.$$

Slops. Clothes and bedding supplied from the ship's stores to the seamen, but at their expense.

Slotting Machine. A machine in which a tool moves vertically, in the manner of a mortising chisel, so as to cut out slots or mortises, or to pare round the edge of any object requiring to be made fair and smooth on the edge. Slotting machines were originally constructed for cutting key-seats in toothed wheels; but they are now used for a great variety of purposes.

Slough (A.-Sax. slog). A Surgical term applied to the separation which ensues between dead and living parts.

Slow Match. [MATCH.]

Slue. In Naval language, *to slue* is to turn a cylindrical piece of timber, as a mast or boom, about its axis, without moving it out of its place.

Sluice (Dutch sluis, Ger. schleuse, from schliessen, *to close*). In Hydraulics, a frame of timber, stone, or other solid substance, serving to retain and raise the water of a river or canal, and, when necessary, to give it vent.

Slur. In Music, an arch ⌒ connecting two or more notes not on the same degree, indicating to the performer that in playing they are to be united as much as possible.

Smack (Dutch smak-schip). A small decked or half-decked vessel, of various rig, used principally in the fishing trade and by pilots.

Smalcald, League of. [REFORMATION.]

Small Arms. Under this name are included all those hand fire-arms which do not come under the head of *ordnance*; as muskets, carbines, and pistols. There are now (1866) in the British service 32 different small arms, all of which, with one exception (naval smooth-bored pistol), are rifled. The table on the next page describes the most important of these arms.

In addition to the seventeen arms described in the table, there are four others still in the service, which are being superseded; and eleven for Indian service only, completing the total number of thirty-two.

As regards the systems of rifling in the service arms, the Whitworth rifle has an hexagonal, the Westley Richards' carbine an octagonal, the Lancaster carbine an elliptical bore. The rifling of the Enfield rifle is simple, and much like the Woolwich system employed for ordnance. The Sharp carbine is rifled on this system with three grooves.

It has been decided to supersede the present muzzle-loading arms by breech-loaders; and for this purpose various inventors and gun-makers were invited to send in patterns for converting the present service Enfield rifles into breech-loaders. It is impossible, in the limits of this article, to enter into the various systems for closing the breech. The chief competitors were Messrs. Westley Richards, Green, Mont Storm, Joslyn, Shepard, Wilson, Snider, Henry, and Lindner. The system of Mr. Snider, in which the cartridge contains within itself its principle of ignition, has been selected. The great advantage which a cartridge of this nature possesses is that it does away with the necessity for fixing a cap when loading, which always occupies some time, and in cold weather is a difficult operation.

The Snider converted Enfield (figs. 1 and 2),

Snider's Converted Enfield.

which has been improved by the patentee in conjunction with the superintendent of the government small-arms factory at Enfield, appears to be a simple and safe weapon, little liable to get out of order. It is also a cheap weapon, the cost of conversion being only about 15*s*. for each rifle. The method of conversion

is as follows: about two inches of the Enfield barrel are cut away at the breech, and a solid breech-stopper, A, working sideways on a hinge, is placed in the opening thus made. Through this stopper passes a piston, one end of which, B, when the breech is closed, receives the blow from the hammer, while the other communicates it to the centre of the cartridge, thus firing the latter. There is an arrangement for withdrawing the old cartridge case after each discharge, by means of sliding back the stopper on the bar on which it hinges, when a mere tilting action of the hand throws out the old case, and the new one can be inserted. With the cartridge described in SMALL-ARM AMMUNITION there is no escape of gas, and the accuracy of the arm is about 33 per cent. greater than that of the muzzle-loading Enfield with its ordinary service cartridge. As many as 15 rounds have been fired from it in a minute, showing a rapidity of fire more than five times as great as that of the unconverted arm. It is remarkably free from fouling, and little liable to deterioration by bad weather.

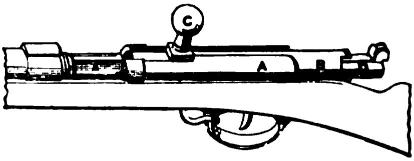
On comparing it with the Prussian needle-gun, its advantages are at once apparent. It is much simpler in construction, and lighter, weighing only 9 lbs. 5½ oz., while the needle-gun weighs 10 lbs. 11 oz.; the latter arm also cannot be fired so rapidly.

The success of the needle-gun in the campaign of Bohemia is not to be attributed to any peculiar advantages of that form of breech-loader, but to the vast superiority of any safe breech-loading small arm with cartridges containing their own principle of ignition over any muzzle-loading arm requiring to be capped.

The construction is complicated, but may be thus roughly stated. At the breech end of the barrel is an open channel A, in which slides an iron tube B, with a handle C. This tube is pierced in front with a small hole, through which the needle passes to ignite the cartridge. The needle is a thin steel wire about $\frac{8}{100}$ inch

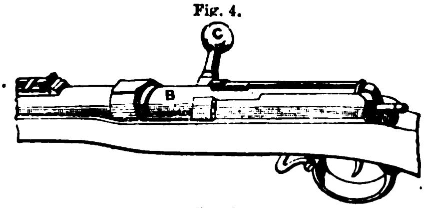
in diameter, bluntly pointed, and is carried in a small tube D in the rear part of the iron tube B. The tube B is capable of being moved backwards and forwards by means of its handle C, which passes through a perforation in the barrel like a bayonet notch. When the tube is drawn back as far as it can go, an open chamber is left between it and the barrel (as in fig. 3). The needle is drawn back

Fig. 3.



Open.

Fig. 4.



Closed.

Prussian Needle-gun.

with and by the tube D, forces back a spring, and becomes fixed by the trigger catch. The cartridge is now introduced into the chamber, and the tube B is pressed forward till its end is in contact with the rear of the barrel; the handle is turned round in the notch, and the breech is closed (as in fig. 4), the needle remaining fixed behind. When the trigger is pulled, the needle is released, and the spring drives it forward into the cartridge, igniting the detonating composition.

The barrel is rifled with four grooves, having a uniform twist of one turn in forty-two inches. The cartridge is described in SMALL-ARM AMMUNITION.

Swords, lances, cutlasses, boarding pikes, and boarding axes, are sometimes called *small arms*.

Small Wares. A commercial term applied to tape, bindings, braid, and other textile articles of that kind.

Small-arm Ammunition. The most important bullets used in our service are: 1. The general service Enfield rifle bullet. [BULLET.] 2. The Whitworth bullet, used with the Whitworth rifle; its length is 1·292 inches, diameter ·442 inches, weight 480 grains; it has a hollow in the base without cap or plug. 3. The Westley Richards bullet, made of lead with five per cent. of tin; it has no hollow in the base, but a belt round the hinder part. 4. Metford's percussion bullet; this is merely an ordinary Enfield bullet, having a chamber down its longer axis, to within one-fifth of an inch of the hollow; this chamber contains four and a half grains of detonating composition; and the bottom is closed with wax. It is intended to explode ammunition waggons.

The cartridges for the Enfield rifle are made in two ways, and called either *rolled* or *bag* cartridges; the former is made of four pieces of paper, the first two forming the powder cylinder; in the bag-cartridge the powder cylinder is made from the pulp; the third paper contains the bullet, and laps over the powder cylinder; the fourth paper joins bullet and powder cylinders together. These cartridges are white. Blank cartridges are made of purple paper, and contain powder only.

Percussion caps have already been described. [PERCUSSION CAP.]

In most breech-loading arms, the detonating composition which ignites the cartridges is contained in the cartridge itself. *Side-fire* cartridges are those in which this is ignited by a blow on the side of the cartridge. *Central-fire* cartridges are ignited by a blow on the centre, and to this class belong the Prussian needle-gun and Snider's converted Enfield, which latter is now adopted in the British army.

B. Bullet. C. Cap.
D. Wooden plug.
E. Clay plug. F. Papier mâché. G. Anvil.
K. Cotton wool.

In the cartridge of the Prussian needle-gun, the bullet B is separated from the powder D by a rolled and compressed paper cylinder A, which is hollowed at the end next the bullet. It has a cavity at C, in which is lodged in front of the powder the fulminating composition to be exploded by the thrust of the needle, which pierces through the powder. The bullet is ogival in form, weighs 487 grains, and is fired with a charge of 75 grains of powder; it has no hollow at the base, and does not expand into the grooves of the piece when fired, but the paper cylinder enters the grooves and imparts the requisite rotation to the bullet.

The cartridge for Snider's converted Enfield, as designed by Colonel Boxer, appears to be the best yet produced. The case A is made of thin sheet brass, rolled into a hollow cylinder, one end of which receives the bullet B, the

other end fitting into the metallic cap C, which contains the percussion or ignition arrangement of the ordinary central-fire nature. The brass case, which is covered with thin paper, uncoils on discharge, and contracts to a slight extent when relieved from the internal pressure of the gas, thus guarding against splitting and escape of gas in the first instance, and facilitating withdrawal in the second. The bullet is externally similar to the Enfield bullet, but has a chamber, as in Metford's bullet, down the axis. This is filled by a wooden plug D; the bullet being thus made lighter than the ordinary Enfield bullet, and the centre of gravity being thrown further back, which improves the shooting. The bullet has also some grooves or cannelures round its base end, which contain the lubricating bees-wax. There is the usual clay plug E, and some cotton wool K, between the powder and the bullet.

These cartridges have been most severely tested; they resist damp to an extraordinary extent, far beyond any probable requirements of a campaign; they are remarkably safe against premature or accidental explosion, while there were only three misfires out of several thousand trial rounds, and those from causes which can be guarded against, while the expense is not much greater than that of the old Enfield cartridge. [SMALL ARMS.]

Smallpica. In Printing, the name of a kind of type three sizes larger than that used in this work. There are at the present day a greater number of books printed in this type than in any other. [TYPE.]

Smallpox. Called also *Variola*, because it changes and disfigures the skin. There are two forms of this disease, generally called by medical men the *distinct* and the *confluent*; in the former the pustules are separate, in the latter they coalesce. *Distinct smallpox* begins with the usual symptoms of inflammatory fever; i.e. pains in the back and loins, sickness, drowsiness, headache, pain upon pressure about the region of the stomach, and in infants one or more epileptic fits. About the end of the third day little red spots, much resembling flea-bites, make their appearance upon the face and head, which spread during the fourth day over the breast, body, and limbs; about the fifth day a circular vesicle forms upon each little point, depressed in the centre, surrounded by an inflamed margin, and containing a colourless fluid, and at this time the eruptive fever disappears; about the sixth day the throat becomes sore, and the saliva viscid; and about the eighth day the face is swollen, and the pustules round, prominent, and prevalent; about the eleventh day the pustules attain their full size (about that of a pea), and the matter which they contain becomes opaque and yellow, and a dark central spot appears on each; the swelling of the face subsides, and is transferred to the hands and feet, and more or less secondary fever now ensues. After this, the pustules become rough, break, and scab over, and a dark brown spot remains for some days; and if the pustules have been large an indentation is left; the remaining symptoms gradually subside, and about the seventeenth or eighteenth day the secondary fever disappears.

Confluent smallpox is ushered in by a fever of a far more violent and threatening character; all the incipient symptoms are aggravated; delirium or coma may attend them: and in infants there is diarrhœa, and in adults salivation. The eruption is very irregular in its progress and appearance, and usually preceded by red patches upon the face, from which the pustules emerge on the second day in the form of clusters somewhat resembling measles. Their progress is rapid; but instead of being circular and well defined, they are flat and irregular in shape, and contain a brownish fluid quite unlike pus: the intermediate species between the clusters are generally pale and flaccid. The tumefaction of the face and running of saliva are greater than in the distinct spaces; and the fever does not cease upon the appearance of the eruption, but about the ninth day it generally becomes aggravated, the eruption livid and accompanied by the petechiæ or purple spots; and about the eleventh day from the commencement of the disease it often terminates fatally.

This disease is the effect of a specific contagion, and is produced either by inoculation, or by exposure to the effluvia from persons suffering under it: in the latter case it is usually called the *natural smallpox*. When the distinct smallpox goes regularly through the stages above described it is rarely dangerous, except from mismanagement; but it often leaves a tendency to inflammatory disorders, and in a scrofulous habit it excites that disorder into activity. Any of the symptoms which have just been described as characterising confluent smallpox are alarming; so is a sudden disappearance of the eruption, or change in its appearance, followed by depression or delirium. In treating the distinct smallpox, the febrile symptoms are to be moderated by cool air, saline and mild acid diluting drinks, and very gentle aperients. Bleeding and purging are in almost all cases to be decidedly avoided. Great irritability may occasionally be allayed by small doses of opium and camphor, or, what is preferable, by muriate of morphia: this will also check diarrhœa, should it supervene. The confluent form generally requires more or less of the treatment which is adopted in low or putrid fever. Obstinate vomiting, which is sometimes not only a troublesome but alarming symptom, is best encountered by the saline draught in the act of effervescence, with a few grains of aromatic confection, and a few drops of tincture of opium.

Smalt (Dutch smelten). A fine blue colour used in painting and printing upon earthenware, and applied to several other purposes in the arts. The finest smalt is made by fusing glass with oxide of cobalt, by which a very deep blue compound is obtained, which when finely powdered acquires a beautiful azure colour.

Common smalts are prepared by fusing mixtures of zaffre, sand, and pearlash.

Smaltine. One of the most important ores of cobalt, being (with Cobaltine) that from which most of the smalts of commerce is manufactured; whence the name. It is an arsenide of Cobalt, composed of 72 per cent. of arsenic, 95 cobalt, 9 iron, and 9·5 nickel. It is found in Cornwall and Cumberland; in Scotland, &c.

The arsenides of cobalt only are, strictly speaking, included under the term *Smaltine*; those varieties which contain Nickel being called *Chloanthite*. [Chathamite.]

Smaragd (Gr. σμάραγδος). In modern times this word is used as a synonym of *emerald*; but it was applied by the ancients to various other precious stones, such as fluor spar, green vitrified lava, green jasper, and green glass. The passage of Pliny (*Nat. Hist.* xxxvii. 5), in which Nero is said to have been in the habit of viewing the gladiatorial combats *in a smaragd*, is generally understood to signify a smooth polished mirror made of some of the above substances; but it has been maintained that the emperor was short-sighted, and used a concave eyeglass formed of the smaragd. The smaragd is found in various parts of Europe, Asia, and America; but particularly in the Ural mountains, and in the mines of Chili and Mexico. [Emerald.]

Smaragdite (Gr. σμάραγδος). A peculiar laminated form of Augite or Hornblende, of a bright emerald-green colour. It is found in Switzerland, at Monte Nova and near Geneva; also in Corsica, in Felspar.

Smart Money. The Military term for the fine to be paid, in order to escape prosecution, by a recruit who has accepted enlisting money, but refuses to be attested.

Smart Ticket. A certificate of a seaman's having received a wound or hurt.

Smectite (Gr. σμηκτός, *smeared*). A greenish kind of Halloysite from Condé in France.

Smectymnuus. A work against episcopacy, in reply to Bishop Hall, was published shortly after the assembling of the Long Parliament under this title, which was obtained by clubbing together the initials of the names of the five authors, Stephen Marshall, Edward Calamy, Thomas Young, Matthew Newcomen, and William Spurstow. This book was followed by a long and vehement controversy, in which Milton took part in reply to the rejoinders of Archbishop Usher.

Smelite (Gr. σμήλη, *soap*). A kind of Kaolin (China Clay), found near Telkebanya in Hungary.

Smell. This sense resides in the mucous or pituitary membrane which lines the nostrils, and the surface of which is more or less convoluted or extended in various orders of animals. In the human subject this membrane is highly vascular, and largely supplied, especially in its upper parts, with nervous filaments, or ramifications of the olfactory trunk, which has its origin, by three distinct roots, from the posterior, inferior, and internal parts of the anterior lobe of the brain, and proceeding towards the perforated plate of the ethmoid bone, divides into the small threads just mentioned.

The physiology of odours is a curious and intricate subject, requiring much more experimental investigation than it has hitherto received. The air is the great vehicle by which their various influences are transmitted in the act of inspiring to the olfactory surfaces, and for the diffusion of most odours a certain degree of humidity in the air appears absolutely essential. There is scarcely any sense the degree of perfection of which varies so much in different individuals as that of smell, some being painfully alive to those odorous influences which are not even perceived by others. An obtuseness of this sense is also very frequent, and its almost entire absence by no means uncommon; this is especially the case in certain catarrhal complaints, and in some other affections of the lining membrane of the nose.

Smelt (A.-Sax.). A delicate small fish, of the Salmonoid family (*Salmo eperlanus*, Linn.), separated as a genus (*Osmerus*, Cuv.) by having a transverse row of vomerine teeth, and a row of conical teeth along the palatine and pterygoid bones. The tongue has strong teeth anteriorly and longitudinal rows of small teeth behind. Scales of moderate size; pseudo-branchiæ rudimental; pyloric appendages few and short. The *Osmerus eperlanus* frequents the coasts and numerous fresh waters of Northern and Central Europe.

Smew. The name of the diver called *Mergus albellus* by Linnæus. [Mergus.]

Smilaceæ (Smilax, one of the genera). A small natural order of Endogenous plants with weak or twining stems and reticulated leaves, not distinguishable from those of Exogens. Lindley refers them to a class which he calls Dictyogens, and distinguishes them by their bisexual or polygamous hexapetaloideous flowers, their several consolidated carpels, and their axile placentæ. The drug called Sarsaparilla, or Sarza, is the root of various species inhabiting South America, and is held in high esteem for its diuretic, demulcent, alterative qualities. They are found especially in the temperate and tropical parts of Asia and America.

Smilacine (Gr. σμῖλαξ). A crystalline principle obtained from Sarsaparilla root.

Smilax (Gr.). An extensive genus of Dictyogens, giving its name to the order *Smilaceæ*, and consisting of climbing shrubs, natives of the warmer, temperate, and tropical regions of both hemispheres. Some of the species furnish the drug known as Sarsaparilla, so called from the Spanish sarza, *bramble*, and parilla, *a vine*, in reference to the thorny stems of the plants.

The Sarsaparilla of the shops consists of the roots, to which are attached portions of the rootstocks, of various species of this genus. It is by no means clearly ascertained what are the exact species yielding the varieties of this drug met with in commerce, but it is sup-

posed to be the produce of *S. officinalis*, *S. medica*, and *S. papyracea*, while other species are mentioned as occasionally used. The species named *S. Sarsaparilla*, which is common in the United States, does not appear to be used medicinally, notwithstanding its name. In commerce, the various kinds of Sarsaparilla are divided into two principal groups, according to the quantity of starchy material which they contain. The mealy Sarsaparillas contain an abundance of farinaceous matter in the inner part of the rind. To this group belong Caraccas Sarsaparilla, the produce probably of *S. officinalis* or *S. syphilitica*; Brazilian Sarsaparilla, which is imported in cylindrical bundles, and is considered to consist of the roots of *S. papyracea* and *S. officinalis*; and Honduras Sarsaparilla, the botanical origin of which is quite unknown. The non-mealy Sarsaparillas are known as Jamaica or Red-bearded Sarsaparilla, which is imported into Jamaica from Columbia, and is probably the produce of *S. officinalis*; Lima Sarsaparilla, which consists of roots, imported not only from Lima but from Costa Rica, and of which *S. officinalis* is supposed likewise to be the source; and Vera Cruz Sarsaparilla, the produce of *S. medica*.

Smithsonite. Hydrated silicate of zinc, composed of 67·4 per cent. of oxide of zinc, 25·1 silica, and 7·5 water. It occurs in colourless rhombic prisms; also stalactitic, botryoidal, granular, and compact; sometimes it is of grey, blue, yellow, green or brown shades, and varies from transparent to opaque. It has a vitreous lustre, is brittle, and becomes phosphorescent when rubbed, and electric by heat. It is found in Cumberland, Derbyshire, and in the Mendip Hills in Somersetshire. Named after the chemist Smithson, by whom it was analysed. The name Smithsonite has also been applied by some mineralogists to Calamine or Carbonate of Zinc.

Smoke (A.-Sax. smoca, Ger. schmauch, akin to Gr. σμύχω, σμώχω). Smoke has been defined as the visible effluvium or sensible exhalation of anything burning. The term is commonly applied to those results of the combustion or ignition of pit-coal which escape from chimneys, and which constitute a serious and well-known evil and nuisance in large towns, manufacturing districts, and almost everywhere where large quantities of coal are consumed. Coal is often a very complex substance; but putting aside its occasional and adventitious ingredients, carbon, hydrogen, nitrogen, and oxygen may be regarded as its ordinary and essential constituents; and the results of its *perfect* combustion would therefore be carbonic acid steam and nitrogen. These substances would constitute invisible and incombustible gases and vapour, and would therefore escape from the chimney top, and blend with the atmosphere, without being perceived. But it unfortunately happens that from the way in which coal is burnt its combustion is far from being perfect, and that besides the above-mentioned products inflammable gases and vapours, together with large quantities of very finely divided carbon, constituting soot, and black and brown smoke, are vomited forth from the chimney shaft, not only contaminating the air, but also occasioning loss of fuel.

There are many practical difficulties in the way of burning smoke, but experience has shown that none of these are of such a nature or magnitude that they may not be overcome by perseverance and skill. They all merge into one common principle, that of mixing air with the combustible vapours and gases generated by the action of heat on pit-coal, so that by virtue of a due supply of oxygen they may be made to burn with flame, and become entirely converted into incombustible and transparent invisible vapours and gases, instead of being, as they now are, only partially burned, their carbon being precipitated, and escaping, together with the other imperfectly consumed matters, into the air.

But to carry out that object a high temperature must be maintained within the furnace; and it is consequently easier to burn the smoke in metallurgic furnaces where it comes into contact with red hot surfaces, than in the furnaces of steam boilers where it is rapidly cooled by the surrounding water. And not only is air and heat necessary to burn smoke, but an adequate time for the operation must be afforded. To this end, combustion chambers are now generally constructed behind the furnace, and fire tiles are interposed either at the bridge of the furnace or at some other suitable part, where they will be intensely heated so as to compel the mixture of smoke and air to encounter hot surfaces before it is cooled very much by entering the flues. The nuisance of smoke has been materially aggravated of late years by the use of coal instead of coke in locomotives, and most of the expedients employed in them to burn the smoke are quite ineffectual. In common land boilers, where slow combustion can be maintained, the smoke will be effectually burnt if the coal is first placed on a dead plate at the mouth of the furnace, where it will be coked, and the gases will be burned by passing over the fire. This, however, involves two operations in stoking, viz. that of pushing back the coked coal upon the fire and of refilling the dead plate with a fresh supply of raw coal. By the use of the revolving grate, however, this labour may be saved, as in that arrangement the coal is constantly precipitated by suitable apparatus on the part of the grate near the door, and the smoke passing from it over the incandescent fuel on the bars is burnt, while by the time the gases have been all expelled, the revolution of the grate will have carried it to the part of the furnace farthest removed from the door, where it will in its turn promote the combustion of the gases proceeding from the coal last introduced. These plans, however, are hardly applicable to marine, and not at all applicable to locomotive boilers. But in all furnaces in which there is a good draught (and in locomotive furnaces the draught is very great) the

smoke may be effectually burnt by making it pass through the fire. This may be accomplished by placing the fire between vertical bars through which the air enters, and vertical tubes through which water circulates, and past and among which the smoke has to proceed in its way to the chimney. By keeping the outside solid bars sufficiently long, and the inside tubular bars sufficiently short, the smoke will have to descend for a certain distance through the fire before it can escape; and it will thereby be completely consumed. The smoke from houses may be entirely avoided by the use of coke or Welsh coal instead of bituminous coal; such fuels occasion a little more trouble in the lighting of fires, but they are otherwise much better adapted for domestic purposes than bituminous coal. The laws against smoking furnaces should be rigidly enforced, and effectual means for obviating the nuisance will then be quickly adopted.

Smoke Ball. In Artillery, a paper shell filled with a composition which, when ignited, emits volumes of smoke. It is thrown into mines or other confined situations to suffocate an enemy's working parties; and has been used as a signal in the arctic regions.

Smoke Quartz or **Smoky Quartz.** A variety of Rock Crystal with a smoke-brown coloured tint, found in Scotland, Bohemia, Nova Scotia, &c. The transparent wine-yellow and clove-brown crystals which are the true Cairngorm, are included under this variety, as are also the False Topaz, Morion, Topazine Quartz, &c.

Smoke Sail. A small sail hoisted before the funnel of the galley, when the ship is at anchor head to wind, to screen the quarter deck from the smoke.

Smoke Stack. In a steam-vessel, the funnels and steam-pipes rising from the flues and boilers above the deck. In ships of war, they are commonly telescopic, to be drawn down out of shot in time of action.

Smorzato (Ital. extinguished). In Music, a term denoting that the violin bow is to be drawn to its full extent, but gradually lighter till the sound is nearly lost.

Smuggling (Dutch smokkelen). The offence of privately importing or exporting goods, the importation or exportation of which is either prohibited or loaded with heavy duties. Thus, before the Bank Act of 1819, the exportation of British gold coin was an offence against numerous statutes and the received canons of monetary policy; and at all times when the legislature has imposed a tax on articles of foreign produce, the attempt to introduce privately such articles either for consumption or sale, is an offence against the revenue, by which the honest consumer, who has half paid the tax, is defrauded. Such acts are called smuggling. Analogous to them are frauds on the excise, i.e. on internal taxes, as contrasted with those which are levied at the ports, or in the act of taking goods out of bonded warehouses. For obvious reasons, frauds on the excise are far less common than frauds on the customs; except in the case of illicit distillation, and perhaps in the manufacture of malt.

The tendency to smuggle foreign goods on which duties are ordinarily and legally payable is generally to be traced to the folly of governments, to the demand for articles on which excessive customs duties are levied, and to the sympathy and co-operation of such as are debarred from the use of these articles with the persons by whom their needs are unlawfully supplied. It is not the case, it may be confidently asserted, that high duties levied for the intelligible needs of government are necessarily provocative of smuggling, for very heavy taxes may be and are payable from many articles without this consequence; thus, the tax on tobacco is far in excess of its value, and if the community were bent on enjoying this luxury by unlawful means, it does not seem likely that any preventive service could effectually check its illegal importation; but the community acquiesces in the tax, and public opinion is, on the whole, hostile to those who attempt to evade the legal obligation of paying a customs debt. The decline of the practice, once common enough, of smuggling tobacco, is, we may be convinced, due quite as much to the force of a judgment on the part of the people, endorsing the equity of the law, as it is to any regulations and precautions on the part of the custom house and of its officers.

The case is very different when a tax is levied either to sustain a particular interest in the community, or when government attempts to enforce certain sumptuary laws on the public, or when there is a general impression that the tax is levied in defiance of equity or expediency. Thus, in the old days of the East India Company's trading monopoly, the smuggling of tea was a regular and acknowledged branch of business; during the existence of the Gin Act, when an attempt was made to force abstinence on the people by means of a prohibitory excise and customs duty, private stills were universal, and smuggling excessively common; and when the law forbad the exportation of coin, the most respectable houses were engaged in an illicit trade in melted sovereigns or guineas.

An abolition of restrictions on trade in the first case, an abandonment of the affectation on the part of government of inculcating personal morality by the machinery of a police force, and such a course of fiscal arrangements as induces the public to recognise in the impositions of customs and excise duties a mere intention of procuring a necessary revenue in the easiest and least oppressive way, are fatal to the practice of smuggling, not so much, probably, because the temptation to smuggle is taken away, but because sympathy with and encouragement of the smuggler cease. The smuggler is no longer the agent by whom oppressive laws may be evaded, and impertinent interference avoided, but a mere rogue who commits at once a fraud on the public purse and a wrong on the honest dealer.

The tendency towards smuggling has been indirectly stimulated in no slight degree by the policy of government. While all administrations attempt to coerce by very energetic measures any frauds on their own revenue by means of illicit trade or illicit productions, they have been by no means equally sensitive to the duty of checking frauds on the revenue of neighbouring nations, and in many cases have treated such frauds as a matter of the highest public policy. Thus, the Spanish government, either from falling into the common delusion of the protectionist theory, or in retaliation for the action of our government, having put prohibitive duties on English goods, the British government recognised that the chief value of Gibraltar lay in the convenience which it afforded for a smuggling trade, and diligently furthered this trade. So, again, during the time in which the first Napoleon attempted, by his insane and suicidal Berlin and Milan decrees, to check or even destroy the exportation of British produce to all parts of the Continent over which his authority or influence extended, and enforced his decrees by inflicting the most sanguinary punishments on offenders against these regulations, the British government encouraged smuggling by every means in its power, and occupied several islands in which to store its produce, and from which to evade the decrees in question. It is very hard, however, for a government to induce a belief in the immorality of an action which it treats as a high crime and misdemeanour under one set of circumstances, and recognises as a true course of policy under another.

We do not doubt that the most obvious way in which smuggling could be put down is to render it unprofitable, but we cannot also doubt that an equally effective and a more enduring check is to render it unpopular: and that no better means can be found for this result than those which lead the public to understand that the policy of the government in the imposition of taxes is purely fiscal, and that therefore any fraud on the revenue is a robbery of honest tax-payers. It is by these means that the practice of smuggling has been, as all admit, checked. For although the tariff of duty-paying commodities has been much simplified, there is still a number of articles the duty on which is many times more than the prime cost, and which, therefore, on the ordinary hypothesis that smuggling is the inevitable consequent of high customs duties, should be smuggled largely. Public morality is not much furthered by the regulations of government, but it may be, and often is, very seriously injured by an impression that the action of government is unfair, capricious, or interested, or that the proceeds of the public revenue are squandered.

It is possible that smuggling has been to some extent discouraged by the provisions of 16 & 17 Vict. cap. 107, by which armed combinations for smuggling purposes are made felonies. But it is certain that such an Act would be inoperative, if the growth of public morality had not prepared the nation to treat smuggling as a social and not merely as a political crime.

Smut (A.-Sax. smitta). A disease incidental to corn crops, by which the farina of the grain in the whole body of the seed is converted into a black soot-like powder. It is to be regarded as a fungus growth and receives its name from the sooty, dusty mass into which the substance of the seed and seed-vessel is converted under its influence. Mr. Berkeley tells us that means used in preparing seed-corn against bunt may be effectual against smut; but this can scarcely be the case, as the spores of the latter are so much more freely dispersed.

Smyrnium (Gr. *σμύρνα*, *myrrh*). The name of a genus of *Umbelliferæ*, one species of which, *S. Olusatrum*, not uncommon in some parts of Britain, was formerly used as a pot-herb. This plant, commonly called Alisander or Alexanders, is a biennial, usually met with near the sea, as well as in the vicinity of old houses, where it might have been formerly cultivated. Before the introduction of celery, the leafstalks, which are the edible parts, were blanched, and used either as a salad or pot-herb. The flavour somewhat resembles that of celery, but it is stronger and not so agreeable, on which account it has been neglected, and has almost entirely gone out of cultivation.

Snail (A.-Sax. snægel). The name given to the common shell-bearing molluscous animal of this country, applicable to all the various kinds of terrestrial and arboreal species of pulmonated or air-breathing testaceous gastropods. It is properly restricted to those of the genus *Helix*, in which the aperture of the shell is lunate, wider than it is deep, with the margin commonly thickened and reverted. The common snail of this country is the *Helix nemoralis*. In the localities where the Roman colonists dwelt, a larger Italian species, *Helix pomaria*, has become acclimated; it is susceptible of great increase of size by artificial feeding, and was esteemed a dainty by the Romans.

Snail Plant. The popular garden name for the *Medicago scutellata*, the fruit of which resembles snails.

Snake (A.-Sax. snaca). The common term applied to all ophidian reptiles. The British harmless snake is the *Coluber natrix*, Linn.

Snake Root. This term is applied to the root of the *Aristolochia serpentaria*, a native of Virginia: it is a fibrous, aromatic, and bitterish root. The infusion is occasionally used as a tonic and diaphoretic: in typhoid fevers it is a good adjunct to Peruvian bark, and to quinia.

Snake Weed. The great Bistort, *Polygonum bistorta*. The root is *twice bent* on itself, hence the name. This root contains starch, which renders it nutritive; hence, in Siberia, it is roasted and eaten.

Snake Wood. The wood of the *Strychnos colubrina.* Supposed to be an antidote to the poison of certain snakes.

Snapdragon. The well-known garden flower, *Antirrhinum majus.*

Snaped Timber. In Shipbuilding, a timber so cut away, that one face is narrower than that opposite to it.

Snatch Block. On Shipboard, a block with a single sheave, and a notch through one side above the pulley, to enable the rope to be lifted in or out, without the necessity of an end being passed through. It is of use where pressure from the side is required to be applied to a rope already in a state of tension, without diminishing that tension.

Sneezing (A.-Sax. niesan, Ger. niesen). A convulsive action of the respiratory organs, brought on by irritation of the nostrils. Violent fits of sneezing are even said, in some instances, to have proved fatal; recourse must in such cases be had to soothing the nasal membrane by the application of warm milk and water, or decoction of poppies.

Snifting Valve. The valve through which the air and water are expelled from a condensing steam engine when the engine is blown through. In starting a condensing engine, the first operation is to produce a vacuum within the condenser, which is accomplished by opening a valve called the *blow-through valve,* which permits the steam from the boiler to pass through the engine, filling all its vacant spaces, and finally escaping through the snifting valve, which is of the spindle construction, like a safety valve, and which is lifted by the steam. The steam expels all the air and water within the engine; and when this has been done, the blow-through valve is shut, the snifting valve shuts of its own accord, and the steam within the engine speedily condenses from the escape of heat from the surfaces of the engine, and a vacuum is consequently formed, which enables the engine to be readily started.

Snipe (Dutch snip). The common name of the *Scolopax gallinago,* Linn. This bird is a plentiful species in most parts of Great Britain. In wet seasons it resorts to the hills and higher grounds; in ordinary seasons it frequents marshes. Its principal food is worms, in quest of which it penetrates the soft earth with its long and slender bill, which is especially organised for that purpose.

Snow (Ger. schnee, Fr. neige, Lat. nix, nivis, Gr. νίφα). Congealed water, which falls from the atmosphere. Very little is yet known respecting the formation of this meteor. The only observations which may be considered as in any degree complete have reference to the different forms which the flakes assume. This subject was considered by Kepler, Hooke, Cassini, Muschenbroek, and many others; but the most interesting series of observations hitherto obtained are those of Scoresby, and more recently of Glaisher, who have reduced the different forms into classes, and given a number of excellent representations of the flakes in different states. The crystals belong to the rhombohedral system, and when examined with a lens are generally seen to consist of stars of six rays formed of prisms united at angles of 60°, from which other prisms shoot at similar angles, giving the whole an appearance of exquisite beauty and great regularity. The variety of modifications is probably owing to the state of the atmosphere when the snow is formed. If the crystallisation takes place when the air is calm, the crystals will be regularly formed; but they will be irregular and imperfect when the air is much agitated. Sometimes the flakes are granular, and present no traces of crystallisation.

An experiment of Professor Tyndall's has shown in a very beautiful manner that ice is but an agglomeration of snow crystals; the transparency of the former being due to the expulsion of the air entrapped in, and causing the whiteness and opacity of the latter. By exposing a piece of clear ice to the radiation from the sun, a flame, or a bright fire, numberless minute specks are suddenly developed within the ice. After a few seconds' exposure these attain a diameter of about 0·1 of an inch, and when examined through a lens are seen to be little six-rayed stars; the less developed ones resembling tiny flowers with six petals each. These *ice-flowers* are composed of water resulting from the disintegration of the ice by radiant heat, and indicate the way in which the ice originally crystallised; hence, as we should expect, their planes are parallel to the plane in which the ice froze. When the ice-flowers are compared with snow crystals, the two are essentially the same, the rays and serrations in both following the common angle of 60°.

Snow is much less dense than ordinary ice. The bulk of a given weight of ice is only about one-twelfth greater than that of the water from which it is formed, while the bulk of new-fallen snow is ten or twelve times greater than that of the water obtained by melting it. At moderate elevations above the sea, and in the mean latitudes, snow most frequently falls after some days of pretty hard frost, and when the temperature of the air, though still a few degrees above the freezing point, is sensibly mitigated. On this circumstance is founded the remark (which, however, does not always hold good), that it cannot snow in very severe cold.

Red Snow.—It had been remarked by the ancients that snow sometimes assumes a red tint, and Pliny ascribes the cause to age: 'Ipsa nix vetustate rubescit.' Many modern observers have described and examined this curious phenomenon, which appears to be met with in all parts of the world. Saussure observed red snow on the Brevan in 1760, and on St. Bernard in 1778; and he supposed the colouring matter to consist of a vegetable dust. Ramond met with it in the Pyrenees, Captain Ross in Baffin's Bay; Parry, Franklin, and Scoresby collected it in still higher northern

latitudes; and it has been found abundantly in New Shetland in latitude 70° south. Among the Alps it is generally found in low sheltered spots, penetrating to the depth of two or three inches; or rather the strata in which it is found (for it occurs overlaid at considerable depths) are about two or three inches in thickness. The colouring matter of this singular substance has been examined by Wollaston, Agassiz, R. Brown, De Candolle Thenard, Bauer, &c. Dr. Wollaston first remarked that it is composed of minute spherical globules, which have a transparent envelope, and are divided into seven or eight small cells filled with a species of red oil insoluble in water. Mr. R. Brown and De Candolle supposed the globules to be a kind of alga. Mr. Bauer (*Phil. Trans.* 1820) found the globules to be exactly identical in snow collected in Baffin's Bay and New Shetland; and he supposed them to be a small fungus of the genus *Uredo*, forming a peculiar species, to which he gave the name of *Uredo nivalis*. Red Snow is really an alga, now known under the name of *Protococcus nivalis.*

Snow Line, or Limit of Perpetual Snow.—Since the temperature of the atmosphere continually diminishes in ascending from the surface into the higher altitudes, there must be in every latitude a certain limit of elevation at which the air attains the temperature of freezing water. This limit is called the snow line, or line of perpetual congelation; and the mountains which rise above it are covered with perpetual snow. Within the tropics the temperature varies little throughout the year, and hence the snow line is distinctly marked; but in countries remote from the equator the limit of congelation rises in summer and descends in winter through a band or zone of considerable breadth. The line of *perpetual* congelation is of course the summer limit. The altitude of the snow line, however, is dependent not upon latitude alone, but also on the configuration and aspects of the mountain chains, the extent and temperature of the surrounding plains, the quantity of snow that falls annually, and the multitude of causes which influence the climate of a country. [CLIMATE.] On the Himalaya chain, for example, the limit of perpetual congelation on the northern side is at an elevation exceeding by upwards of 4,400 feet that on the southern side, though the latter is directly exposed to the sun; a circumstance which Humboldt ascribes to the radiation from the great plain of Thibet, the general serenity of the climate, and the rarity of snow in an exceedingly cold and dry atmosphere. No dependence, therefore, can be placed on any general rule for estimating the height of the snow line, and it affords an exceedingly fallacious indication of the altitude of mountains. The following table is given by Humboldt in his *Fragmens Asiatiques*, p. 549. The elevations stated are the heights of the line of perpetual congelation above the level of the sea, and the measures are reduced to English feet.

Mountain Chains	Latitude	Elevation of Snow Line
		Feet
Cordilleras of Quito	0°— 1½° S.	15,730
Cordilleras of Bolivia	16 —17¾	17,060
Cordilleras of Mexico	19 N.	15,030
Himalaya, Northern side	31	16,940
Himalaya, Southern side	31	12,470
Pyrenees	43	8,950
Caucasus	43	10,870
Swiss Alps	46	8,760
Carpathians	49	8,500
Altai range	50	6,395
Norway, Interior	70	3,518
Norway, Coast	71½	2,302

(See, in addition to the works already cited, Scoresby, *Account of the Arctic Regions*, 1820; Humboldt, 'Mémoire sur la Limite de Neige perpetuelle dans les Montagnes de l'Himalaya, et les Régions Equatoréales,' in the *Annales de Chimie*, tome xiv.)

Snowball-tree. The sterile-flowered variety of *Viburnum Opulus*, commonly known as the Guelder or Gueldres Rose.

Snowdrop. The name of one of our earliest flowers, belonging to the genus *Galanthus*, which poets designate the 'first pale blossom of the unripened year.'

Snowdrop-tree. *Chionanthus virginica*, a handsome hardy tree, bearing a profusion of white flowers.

Snowflake. The name given to the *Leucojum*; a spring or early summer flower, much resembling a snowdrop.

Snuff (Dutch snuif). Tobacco prepared for use by being dried and ground into powder. It is made from the stalks only of the tobacco plants, from the leaves only, or from a mixture of both stalks and leaves. In this way, and by mixing these qualities in varying proportions, the many different kinds of snuff are produced. High-dried snuffs owe their peculiarities to being dried so as to produce a kind of scorched flavour. Scotch snuff is manufactured wholly, or almost wholly, of tobacco stalks.

Sny. An expression for the position of a curved plank worked edgeways into the bow of a ship.

Soap (Ger. seife, Gr. σάπων, Lat. sapo). This useful compound is obtained by the action of alkaline upon oily substances. There are, accordingly, a great variety of soaps; but those commonly employed may be considered under the heads of: 1. Fine white soaps, scented soap, &c.; 2. Coarse household soaps; 3. Soft soaps. The materials used in the manufacture of white soaps are generally olive, palm and other oils, and carbonate of soda: the latter is rendered caustic by the operation of quicklime, and the solution thus obtained is called *soap ley*. The oil and a weak ley are first boiled together, and portions of stronger ley are gradually added till the soap, produced by the mutual action of the oil and alkali, begins to become tenacious and to separate from the water; some common salt is added to promote the granulation and separation of the soap; the fire is then drawn, and the con-

tents of the boiler allowed to remain for some hours at rest, so that the soap may more completely collect. When it is perfect, it is put into wooden frames or moulds; and when stiff enough to be handled, it is cut into oblong slices and dried in an airy room. Perfumes are occasionally added, or various colouring matters stirred in whilst the soap is semifluid, to give it a mottled appearance. The Spanish soap is *marbled* by stirring into it a solution of sulphate of iron, which is decomposed by the soap, and black oxide of iron separated in streaks and patches through the mass. The action of the air converts the exterior into red oxide, whilst the interior long retains its black colour; hence a slice of this soap presents a black mottled centre, surrounded by a reddened external layer.

Common household soaps are made chiefly of soda and tallow and other common fats. Yellow soap has a portion of resin added to it. Soft soaps are generally made with potash instead of soda, and fish oil. The common soft soap used in London is a compound of this kind; it has a tenacious consistence, and appears granulated. Soap is soluble in pure water and in alcohol; the latter solution *jellies* when concentrated, and is medicinally known under the name of *opodeldoc*. When carefully evaporated, the soap remains in a gelatinous state, which forms, when dry, the article sold under the name of *transparent soap*.

The earths and common metallic oxides form *insoluble soaps*; and accordingly these are precipitated when earthy and metallic salts are added to solution of soap. It is the sulphate of lime and carbonate of lime in common spring water which thus render it unfit for washing, and give it what is termed *hardness*; and, upon this principle, a spirituous solution of soap is a simple and valuable test of the fitness of any river or spring water for the purposes of the laundry. If it merely renders the water slightly opalescent, as is the case with rain and other soft waters, it may be used for washing; but if it become milky, it is usually too hard to be conveniently employed; and when we wash with hard water, the separation of the insoluble calcareous soap is extremely disagreeable: it adheres to the skin, and soils instead of cleansing it.

The chemical nature of soap has been laboriously examined by Chevreul, who has shown that the alkali in the process of saponification converts the oil into peculiar *acids*, the elain of the oil forming *oleic acid*, the stearine *stearic acid*, and the margarine *margaric acid*; so that soluble soaps are oleates, stearates, and margarates of soda and potash. He has enumerated several other fatty acids similarly produced.

All new soaps contain a considerable portion of adhering water, a great part of which they lose when kept in a dry place; hence the economy and excellence of *old* soap; and hence the dealers in soap generally keep it in a damp cellar, that it may not lose weight by evaporation, or sometimes immerse it in brine, which does not dissolve it, but keeps it in its utmost state of humidity.

Soap may be considered as a necessary of life; in all civilised countries its consumption is immense. According to Pliny, the invention of soap must be ascribed to the Gauls, by whom, he says, it was composed of tallow and ashes, though the German soap was considered the best. The great seats of the soap manufacture in Great Britain in 1852 were London, Liverpool, Bristol, Runcorn, Glasgow, Greenwich, Gateshead, and Warrington. Thus of 184,725,265 lbs. of hard soap made in 1851, London supplied 44,034,102 lbs.; Liverpool, 39,384,595 lbs.; Bristol, 12,898,630 lbs.; Runcorn, 11,787,360 lbs.; Glasgow, 10,642,219 lbs.; Greenwich, 8,712,130 lbs.; Gateshead, 7,131,590 lbs.; Warrington, 5,147,090 lbs. These figures are supplied from the returns of the last year on which soap was liable to an excise duty, for the tax on soap was repealed in 1853. Up to 1833, the tax had been 3*d*. per lb. on hard soap; it was then lowered to 1½*d*. In 1852, the net revenue derived from soap was 1,126,046*l*. At present it is not possible to determine with any certainty what is the annual manufacture of soap, but it is certain that the amount has increased enormously. The amount exported from Great Britain and Ireland is not large, and appears to diminish, ranging between 15,000,000 and 25,000,000 lbs. [FATS; OILS.]

Soap Bubbles. The addition of a small amount of the soluble salts of the fatty acids to water modifies the cohesion of the particles of that liquid in a remarkable degree, and permits of bubbles being formed of considerable size and permanence. The soda soaps possess this property in the highest degree, and the method of blowing soap bubbles with a tobacco pipe is too familiar an experiment to require description. The extraordinary distensibility of the bubble is dependent on the equality of the strain in all parts of the film; hence it follows that all circumstances which derange this equilibrium cause the destruction of the bubble, as is seen in the case of contact with greasy or porous objects. The evaporation of the liquid necessarily produces the same result, so that the ordinary bubble is as evanescent as beautiful. When the liquid film becomes sufficiently thin, it begins to exhibit the colours produced by the interference of light. [INTERFERENCE.] These tints are frequently of great splendour, and when closely examined are seen to consist of sinuous streaks which mark the lines of equal thickness of film. The bubble solution of M. Plateau, by increasing the permanence of the films, allows these effects to be more readily observed, and renders soap bubbles available for many physical experiments. The recipe for this solution is as follows: Dissolve one part of *pure* oleate of soda in 50 parts of distilled water, and mix this solution with two-thirds of its volume of glycerine. Bubbles blown with this solution can be preserved upon rings

of iron wire for many hours, or attached to small discs of paper held by a thread. The colour-effects in these bubbles can best be examined in the following manner. The stage of a compound microscope is covered with black paper or velvet and a loop of wire is placed on it to form a support for a small bubble. The latter is illuminated on its upper surface by a good condenser, and the light thus reflected is received on an object glass of low power. By this means optical effects of great splendour and variety become evident, depending on the degree of attenuation of the film. The thickness of the latter is estimated to be usually somewhat thicker than that of ordinary gold leaf.

Soap-test. On washing in hard water no lather can be obtained until the lime and other hardening salts have been decomposed by, and have decomposed, the soap. The product of the decomposition is the well-known *curd* which floats on the surface of the water. This action being definite, the *hardness* of waters may be determined by adding to equal quantities of them a solution of soap of known strength until a permanent lather is produced on shaking. Such a soap solution is called a *soap-test*.

Soapstone or **Steatite.** A hydrated silicate of magnesia, with a smooth greasy feel like that of soap, and so soft as to yield to the nail. It is a massive variety of Talc, which, when pure and compact, is much used as a refractory material for lining furnaces, being infusible in any ordinary furnace heat. It is easily turned in the lathe or cut with knives and saws, and is made into culinary vessels.

When very strongly heated, Soapstone loses the small portion of combined water which it contains, and becomes harder and susceptible of polish. In this state it is made into jets for gas-burners, which have the advantage of not being liable to rust or corrosion. When reduced to powder, it is used like Plumbago as a lubricator and to diminish friction, as well as to give a surface to some kinds of paper-hangings.

The soapstone of Mylos is an important article of commerce in Turkey and Russia, where it is used instead of soap.

It is found in Cornwall near the Lizard Point in Serpentine; at Portsoy, Banffshire, and in Canada. [STEATITE; TALC; VENETIAN CHALK.]

Soapwort. The common name for *Saponaria*, and especially *S. officinalis*.

Soave, Soavemente (Ital. *sweet, sweetly*). In Music, a term denoting to the player that the music to which it is prefixed is to be executed with sweetness.

Sobriquet. In French, a burlesque appellation or *nickname*. The word has been variously derived from the Lat. subridiculum, subrusticum, and the Gr. ὑβριστικόν, &c. There is a curious dissertation in vol. xiv. of the *Hist. de l'Acad. des Inscr.* on the authority of these appellations in history.

Socage (Mod. Lat. socagium, from A.-Sax. soc, *privilege*). This term denotes, according to Blackstone, in its original and most extensive signification, a tenure by any certain and determinate service. The sokemen at and immediately before the Norman conquest appear to have been in the lowest ranks of free cultivators of the land, being classed along with the villein in a law of Edward the Confessor. But by the time when the works of Bracton and the author of *Fleta* were compiled, socage had come to signify any tenure not military or quasi-military; i.e. either where military services were due (tenure in chivalry or by knight service), or other services of an honorary kind, such as by the French feudal law were due on what were called imperfect fiefs (tenure by grand serjeanty). Socage, therefore, comprehended various descriptions of tenure, and has been generally divided into *free* and *villein* socage. In free socage, the services were certain, and, in the feudal sense, not base or dishonourable, as the payment of an annual rent; and none of the feudal incidents of wardship, &c., were demandable in respect of lands so held, although certain aids and reliefs were peculiar to socage as well as to knight service. By the stat. 12 Ch. II. c. 24, when military tenures were abolished, all sorts of tenures held of the king and others (except frank-almoign, copyhold, and the honorary part of grand-serjeanty) were turned into tenure by free or common socage. Villein socage was a species of tenure in lands held of the king by certain villein services, but certain and determinate; from which mixed species of tenure arose that in ancient demesne. Lands so held are deemed to be in certain respects copyhold; and these were within the exceptions of the statute 12 Ch. II., and still subsist. [TENURE.]

Social Science. The examination of the various facts and principles under which society is constituted, and by which it is regulated, has in the course of time, and in consequence of the great collection of observations upon the subject, been taken from several different points of view, some of which are precise and determinate, others vague and somewhat shifting. Thus, the purely economical aspect of social life is of the former character. The lines of political economy are positive and unyielding, and the inferences which the economist arrives at are exact, scientific, demonstrative, invariable. On the other hand, the philosophy of politics not only tolerates exceptions, but contemplates the contest or opposition of interests and sentiments as a normal and almost necessary state. The constitution of the several European states differs largely, and, on the whole, all these differ from the political system which has been accepted in the New World, because undoubtedly government is a means to an end, the end being possibly arrived at by various means. This end may indeed be achieved best by particular forms of government, but it seems generally admitted that, unless the form is radically vicious, it is better that the true purposes of society should be worked out gradually by the fair and free

contest of forces, than to impose a special form of government on a people for which it is not willing, or even, if willing, not prepared.

Social science occupies a position intermediate to Political Economy and Political Philosophy. It does not discuss or expound the exact theories of the former, nor does it examine the problems of the latter; but it deals with the effect of existing social forces, and their result on the general well being of the community. Some of these forces are universal and natural, others are municipal or artificial. Thus, the theory of money and its substitutes is a purely economical consideration, the discussion of which has no place in social science. So the various views current on the most effectual and safe representation of the people form part of political philosophy, and as such lie out of the domain of social science. On the other hand, the extension or shortening of human life under sanitary or insalubrious conditions, is a question of eminently social interest, and is, it appears, under ordinary atmospheric or other conditions, susceptible of scientific demonstration. So in another manner, the enquiry into the consequence of certain laws and systems affecting the distribution or accumulation of land is a social question indeed, but one which arises directly from a municipal or factitious ordinance. Furthermore, social science is much more indebted to statistics than political economy is. For example, the ease or difficulty with which the greater part of the community can be supplied with certain necessaries or conveniences of life, such, for instance, as meat, is almost exactly determined by such agricultural statistics as have been lately obtained with extreme difficulty and under the pressure of an exceptional agricultural calamity.

Associations for the purpose of expounding and discussing the principles and details of social science have been long in existence in France, under the name of Sociétés de Bienfaisance. A similar association was established in England, originally in order to give scope for the discussion of many questions which pressed upon the economic science section of the British Association. The first meeting of the Social Science Association was held at Birmingham, under the presidency of Lord Brougham, who has also been, except in the two years 1858, 1859, its president ever since. The business of the association, after hearing an address from its president, is to divide itself into several sections, which have hitherto been four: 1. Jurisprudence and the Amendment of the Law; 2. Education; 3. Health; 4. Economy and Trade, and to hear and comment on papers composed on the various subjects comprised under these general heads. The value of these associations cannot be disputed. They not only form a means by which observations are recorded and truths elicited both by induction and by debate, but they familiarise the public to a greater or less degree with a variety of important questions and a number of unquestionable inferences.

The progress of social science has resulted in the adoption of many important social reforms. Among these may be enumerated the general developement of a sound theory of sanitary science, and the extensive use of precautions against ordinary, epidemic, and endemic disease; the reconstitution of hospital charities; the regulation of prisons and workhouses on sounder and truer principles than those which had hitherto been accepted; the establishment of reformatories and penitentiaries for youthful offenders and reclaimed prostitutes; the extension of education, particularly of middle class and industrial education; and many other important results. Great, however, as have been the effects of these investigations, it cannot be doubted that much remains to be done, and that many problems await their solution at the hands of such persons as have already effected much, and at those of their successors in these branches of practical philanthropy. But social science, the reforms which it institutes, and the charities which it regulates and instructs, occupy of necessity a far inferior position to the developement of the leading subject which is discussed by its advocates, i.e. the amendment of the law. The widest benevolence is but a poor substitute for righteous legislation; or, to state the proposition in another form, one just law is worth a million acts of charity, since its operation is wider and its effects are more lasting.

Social War. In Roman History, this name is given to the struggle (B.C. 91) in which the Italian tribes, who were specially termed the allies of the Roman state, fought for admission into Roman citizenship. This admission would give to them, as to other plebeian citizens, the right to share in the distribution of public lands, and would thus enable them to recover the property of which they had been dispossessed by conquest or encroachment. The war was soon brought to an end by timely concessions of the franchise.

Socialism. (Lat. socialis, from socius; Sansc. sakhi, *a friend*). In Political Philosophy. No very accurate distinction in point of meaning between the words *socialism* and *communism* has been shown. There is, however, a slight difference in common usage, which the following remarks may elucidate.

1. It is held by some theorists that the notion of *property* has no foundation either in right or expediency; that as, in point of fact, the possession of property was originally merely the usurpation of superior strength, so, in a really equitable state of society, this usurpation would altogether disappear; that, in Proudhon's epigrammatic phrase, *property is robbery*. This doctrine of the absolute community of goods is ordinarily designated as *communism*.

2. But between this extreme and that which regards the right of individual property and the use of it as not to be interfered with at all, except in certain extreme cases recog-

nised by ordinary legislation, there is a wide interval. There are many intermediate theories, according to which the use of property ought to be restricted or interfered with, or property itself, when beyond a certain amount, divided, for the common good, or rather that of the majority. These theories commonly pass under the general name of Socialism, and in this sense not only the theories of philosophers, but many existing or proposed laws and usages, may be regarded as Socialist in their tendencies. Such are: agrarian laws, limiting the quantity of land to be held by an individual; laws fixing the maximum of rent, or the minimum of wages; laws interfering in other ways between the capitalist and the labourer (for shortening the duration of labour, and the like); the usages of trades' unions; nay, poor laws, and income taxes limited to the higher classes; all these, some of them innocently, others intentionally, bear in the same direction.

Socialism in this sense had a large part in the institution, and still larger in the theories, of classical antiquity; see the *Republics* of Plato and Aristotle, and the recorded usages of Lacedæmon and of ancient Rome. But in the middle ages it may be said to have entirely disappeared, except in so far as it was kept alive by religious tradition, from the (historical or imaginary) community of goods said to have prevailed among the early Christians. Hence, with the revival of political speculation, socialism may be said to have made its way to the light through two different avenues: 1. That of religious theory (Anabaptists, Herrnhuters, Moravians, &c. &c.), and that of political theory derived from the ancients (More's *Utopia*, Harington's *Oceana*, the ideal reforms of Fénelon, Rousseau, Morelly, and so forth). But the leaders of the first French revolution, amidst all the wild excesses of political fanaticism in which they indulged, were generally either entirely opposed to communistic theories or ignorant of them. Robespierre, for example, who could foresee the probable extension of the republicanism which he advocated into wider changes, wished to declare the 'sacredness of property,' among the fundamental positions of the *rights of man*; but was overruled by others, not because they disapproved of his views, but because they did not see the necessity for proclaiming them.

The first disciples of progress who openly denounced the right of property as the fundamental error of society were Babeuf and his followers, who attempted an insurrection against the Directory in 1797. In his paper, the *Tribun du Peuple*, Babeuf advocated the division of property, without endeavouring to establish any very definite substitute.

Robert Owen of Lanark (born 1771, died 1858), stands in point of date next to Babeuf among the leading advocates of Socialism. (*New View of Society*, 1812; *New Model World*.) Owen's views cannot be said to have assumed any very definite or logical shape, but they undoubtedly assumed community of property as the real basis of social regeneration.

Saint Simon (Claude Henri, Count, born 1760, died 1825), though an older man than Owen, came forward much later as a leader having influence on mankind. His theory partook of the religious as well as the political aspect of Socialism. Property was to be in common. But the enjoyment of it by individuals was to be regulated by a superior authority; a theocratic government, established among mankind by force of superior wisdom and intelligence, was to have the duty of assigning to everyone his allotted task in society and his allotted retribution. His views are chiefly embodied in his *Nouveau Christianisme*, published after his death by Rodriguez. It is strange that theories so absolutely unpractical, and with so strong a tendency to the ludicrous as well as the absurd, should have found favour as they did in France, at the period of the Revolution of 1830. For a time, the 'Saint Simonian' sect played a very conspicuous, if not a really important, part in society; and though after many scandals it was ultimately dissolved by government (1832), many of its leading sectaries have since taken substantial part in public affairs.

Charles Fourier, of Besançon (born 1772, died 1837), was a leader of more original stamp and more powerful mind. Going somewhat deeper into human nature, he developed the theory that all the tendencies of man are naturally good, and that the real function of government is simply to favour and direct their developement. For this purpose not only is community of property necessary, but a thorough disciplinary training of the human race in all the functions of life; to be carried out in distinct communities of a certain number of families, which he designated by the name of 'Phalanstères.' The notions of Fourier, like those of Saint Simon, are chiefly to be collected from posthumous works, especially his *New Industrial World*, 1839.

Etienne Cabet (born 1788) is the last Socialist authority of whom it is necessary to make detailed mention. According to his ideas, an imaginary *state* is to regulate the life of every member of society. This he developed in an imaginary *Voyage en Icarie* (1842), adapted chiefly, it is said, from fragments of old romances. He had success enough (like Owen) to be able to establish a real 'Icaria' by subscription, in the United States (Texas), in 1848. The scheme failed, and its founder was prosecuted in Paris as a swindler (1851) but acquitted.

Society (Lat. societas). The term usually applied to an association formed for the promotion of some object, either literary, religious, benevolent, political, or convivial. Associations formed for commercial purposes are usually styled COMPANIES. The chief literary societies of Europe have been noticed under ACADEMY. The purposes for which *benevolent* and *religious*

societies are formed will be best inferred from the epithets with which they are connected; thus, *temperance* societies are established with a view to promote sobriety, *mendicity* societies for the relief of the indigent, &c.

It is proposed in the present article to give a brief account of the principal societies which now exist, particularly in England, both of the learned and beneficent classes; but the number of those of which special notice can be given is necessarily very limited.

1. 'The Learned Societies of the United Kingdom' are classified by the Rev. Mr. Hume in his account of them (1853) as, 'Metropolitan and Provincial,' in each of the three kingdoms, besides one which he styles 'National, not Metropolitan,' namely, the 'British Association for the Advancement of Science,' instituted in 1831, which holds its meetings annually at places in the United Kingdom designated beforehand.

The Metropolitan Learned Societies are as follow:—

Scientific:
- Royal
- Royal Astronomical
- Geological
- Linnean
- Chemical
- Zoological
- Royal Asiatic
- Royal Geographical
- Ethnological
- Anthropological
- British Meteorological
- Acclimatisation
- Microscopical
- Royal Botanic
- Royal Horticultural
- Entomological
- Photographic
- Institute of Actuaries
- Association for the Promotion of Social Science
- Statistical
- Institution of Civil Engineers

Archæological:
- Antiquaries
- Archæological Institute
- British Archæological Association
- Surrey Archæological
- Syro-Egyptian

Literary and Publishing Societies:
- Camden
- Ecclesiological
- Hakluyt
- Palæontographical
- Ray
- Royal Society of Literature

Medical:
- Epidemiological
- Medical
- Royal Medical and Chirurgical
- Obstetrical
- Pathological

Art and Architecture:
- Architectural Association
- Arundel
- Graphic
- Royal Institute of British Architects
- Musical
- Society of Arts and Manufactures

Various:
- Law Amendment

Besides these societies so called, there are other bodies, such as the Royal Institution of Great Britain, Royal College of Surgeons, Royal College of Physicians, United Service Institution, and London Institution, where, in addition to the holding of stated meetings, other objects are sought to be obtained. Of all these societies, the Royal Society is the most important. It originated in an assembly of persons interested in natural history and experimental philosophy, who began to hold weekly meetings about the year 1645; at first in London, afterwards in two divisions, partly at Oxford, partly in London. In 1663, they were incorporated by King Charles II., as a president, council (twenty-one in number), and fellows, 'for promoting natural knowledge.' Their experiments and discussions are published from time to time under the title of *Philosophical Transactions*. It has 830 British and foreign members: its apartments, granted by the crown, are in Burlington House. Several works on its history have been published; of which the latest and most complete is that by Mr. Weld, its assistant secretary and librarian (1848). [ACADEMY.]

The Society of Antiquaries was founded about 1572 by Archbishop Parker; it assembled, as a private body, for several years in the house of Sir Robert Cotton. It is said to have acquired so much influence as to have excited (it is not easy to see why) the jealousy of James I., and to have been dissolved by him. It was revived in the eighteenth century, and incorporated in 1750 by George II. Its principal object has always been the prosecution of enquiries relating to British history and antiquities, though others are not excluded. Its transactions are published under the title *Archæologia*. There are about 600 members. Place of meeting, Somerset House, in the rooms vacated by the Royal Society on its removal to Burlington House. [ACADEMY.]

The London Society for the Encouragement of Arts, Manufactures, and Commerce, more briefly styled *Society of Arts*, was instituted in 1754; the principal agent in its establishment having been Mr. William Shipley, who was originally a mechanic. The chief objects of its encouragement have been defined 'ingenuity in the arts, useful discoveries and improvements in manufactures, agriculture, mechanics, and chemistry, or the laying open of any such to the public; and, in general, all such useful inventions, discoveries, and improvements, as may tend to the advantage of trade and commerce.' These are promoted, in the first place, by premiums of medals, granted out of the very considerable funds of the society, to inventors, &c., but with the express exclusion of patentees, or those who propose to become such. The society has also become the originator of many similar bodies constituted on the same principles. But its chief, or at least most celebrated, result has been the establishment of the *Royal Academy of Arts*, now an independent body. It has 800 ordinary members.

In almost all these societies, except the Royal Society, the payment of the entrance fee and annual subscription constitutes the most important qualification for membership. In the Royal Society the case is very different; of all the candidates a certain fixed number only is annually chosen and recommended for election by the council.

Most of the important societies have very valuable libraries of reference, and nearly all publish accounts of their proceedings and memoirs, some of which are of the highest importance. The Archæological Institute, British Archæological Institute, and Association for the Promotion of Social Science, like the British Association, hold annual congresses in different parts of the kingdom.

The number of provincial societies, field

clubs, &c., is rapidly increasing, and their present number is very large.

Among the Scottish, Irish, and British provincial societies of eminence may be noticed the *Royal Society of Dublin*, founded in 1734 'for the encouragement of husbandry and the arts;' the *Royal Society of Edinburgh*, founded in 1739; and the *Literary and Philosophical Society of Manchester*, the oldest provincial body, founded in 1781.

In France, the number of scientific and literary societies is very great, and their affairs are to a certain extent subject to the inspection of government. In 1845, it was declared by an *ordonnance royale* that a volume should be published under the Department of Public Instruction, to be styled the *Annuaire des Sociétés Scientifiques et Littéraires du Royaume.* The volume for 1846, which appeared accordingly, contained a short history, and a copy of the rules of nearly 400 such bodies, metropolitan and provincial; the Institut [ACADEMY; INSTITUTE] being regarded as the chief of all. No more volumes of the *Annuaire* were published; but the *Revue des Sociétés Savantes* continues to afford similar information.

2. Among English societies for the promotion of charitable or humane, as distinguished from religious and educational, purposes, may be mentioned: the *Society for the Establishment of a Literary Fund*, instituted in 1790, of which the purpose is to administer relief, by gratuities and pensions, to necessitous literary persons; and the *Royal Humane Society*, 'for the recovery of persons drowned or otherwise suffocated,' instituted in 1774.

3. Lastly, to turn to the societies established among us for educational, as well as for missionary and other religious purposes; it has been said with truth that, with respect to these, England has a right to claim a place in the foremost ranks of civilisation, whether we regard the number or the principles of its religious and benevolent institutions. The notice of a very few leading ones must suffice.

Society for the Diffusion of Useful Knowledge.—This society was originally founded under the management of a committee of gentlemen, assembled under the presidency of Lord (then Mr.) Brougham, in 1822, established and incorporated in 1832. It was at first maintained by subscription, but since its earlier years entirely by the sale of its publications. The revenue derived by it from its works is usually a rent paid by the publisher for the use of the copyright. In this way it has produced (besides many works of inferior art) its Libraries of Useful and Entertaining Knowledge; *Almanac and Companion*; maps; *Penny Magazine*, and *Cyclopædia*, &c. &c.

Society for the Promotion of Christian Knowledge, founded in 1698, has continued from that time to be the principal agent of the church of England for the diffusion of the Scriptures, and her own formularies both at home and in foreign parts.

British and Foreign Bible Society, established in 1804, 'with the sole object of encouraging the circulation of the Holy Scriptures *without note or comment.*' In the recent reports of this body, it claims to have been the means of circulating nearly 50,000,000 copies of the Bible, of which nearly half have been circulated in this country, the larger proportion of the remainder in Europe and Christian America, the rest among Mohammedans and heathens in other parts of the world.

Society, National, 'for promoting the education of the poor in the principles of the established church throughout England and Wales,' founded in 1811, incorporated in 1817. This society was established in order to carry out in a church of England sense that great movement in favour of popular education, which commenced at the end of the last century. Its assistance is furnished towards church schools, when established by private efforts in any parish, by grants of money, books, legal advice, &c. It has also training colleges for masters and mistresses of schools (St. Mark's, Battersea, Whitelands). It has united to itself 12,200 schools, with 1,157,000 scholars.

Society for the Propagation of the Gospel in Foreign Parts was incorporated, in 1701, 'for the receiving, managing, and disposing of funds, contributed for the religious instruction of the Queen's subjects beyond the seas, for the maintenance of clergymen in the colonies, and for the propagation of the Gospel in those parts. The general income of this great society was about 125,000*l.* in 1864, devoted to the maintenance of missionaries and schoolmasters of the church of England in the colonies; and as to certain portions of it, called 'appropriated funds,' to certain special purposes for which these funds were created. The establishment of the church of England in the colonies, now numbering more than forty bishoprics, has been in a great measure created, and is still to a certain extent maintained by its expenditure; and, of late years, certain 'missionary dioceses' (Niger, Orange River, Melanesia, Honolulu, &c.), have been founded, through its agency, in foreign parts beyond the dominions of the crown.

The *Church Missionary Society*, 'for Africa and the East,' was founded at the end of the last century. Its object is to send out, and support, missionaries of the established church, to preach to the heathen in the foreign possessions of the British empire; the missionaries being placed in subordination to colonial bishops, where these are established. The income was estimated, in 1864–5, at 144,000*l.* The chief scenes of its labours have hitherto been the west coast of Africa, the Pacific, North West America, and more especially British India.

London Missionary Society, for missionary exertion in heathen countries; of which the particular characteristic is, that it is not denominational, and comprehends Christians of various persuasions; founded in 1795; its income at present (both ordinary and extra-

ordinary) exceeds 140,000*l.* per annum. Its principal fields of exertion have been the West Indies and South Africa, and the Pacific, in which the Society and Navigators' Islands (Samoa) have been especially superintended by it.

Among dissenting societies of the same class, two perhaps deserve especial notice. *The Wesleyan Methodist Missionary Society.* Its income in 1864 was about 140,000*l.* The principal seats of missionary enterprise in which this great body has established itself, besides foreign European countries, are British North America, the West Indies, and in the Pacific, more especially the Friendly and Feejee Islands, where a considerable native population is under the teaching of its missionaries. The *Baptist Missionary Society*, with similar purposes, has its most remarkable fields of activity in the West Indies, particularly Jamaica.

In the United States the example has been followed by the establishment of various energetic societies for missionary purposes, particularly that of Boston, New England, to which the conversion of the natives of the Sandwich Islands to Christianity, at an early period of this century, was due.

The vast efforts of the church of Rome towards the extension of the Christian religion among the heathen have been for the most part effected under a very different system of organisation, viz. that of papal supervision. [PROPAGANDA.] Of late years, however, that church has called in aid to some extent the principle of voluntary association. *The Society, or Association, for the Propagation of the Faith*, was founded at Lyons in 1822. It has two councils or governing bodies, one at Paris, the other at Lyons. Its transactions are periodically published under the title of *Annals*. Associates of this body are admitted on payment only of a contribution of a sou per week. These contributions (together with such additions as individual liberality makes) are collected by an organisation of *decuries* and *centuries* and *diocesan councils*. The great seat of activity of its missionaries of late years has been in the South Seas, particularly those groups of islands called, in modern geography, Melanesia.

Societies formed for *convivial* or *political* purposes are most usually denominated *clubs* —a term which may be truly said to be exclusively English, and which embraces so many complex ideas that it is all but impossible to reduce it within the limits of a precise definition. The origin of clubs may be said to date from the end of the seventeenth century. It would be superfluous to call to the reader's remembrance the beau ideal of a club which Addison has drawn in the *Spectator*—the Kit-Kat club, which numbered among its members all the most distinguished persons of the day; the Scriblerus club, of which Swift, Harley, Pope, Gay, and Arbuthnot were members; or that still nearer our own times originally held at the Essex Head, which was ennobled by the genius of Johnson, Burke, Reynolds, Goldsmith, Wyndham, and Fox. They were originally instituted solely for convivial purposes; but in the course of time the term *club* was successively adopted by various political associations, both in this country and on the Continent. Since the commencement of the present century, the chief clubs have been either of an avowed political character, as the Carlton, Boodle, and the Reform Clubs; or devoted exclusively to certain classes, as the United Service, the Oxford and Cambridge; or open to all gentlemen on election, without regard to political party or profession, as the Athenæum, Wyndham, &c. There are about forty clubs in the metropolis. They consist each of a limited number of members, varying from 1,000 to 1,500, who are admitted by ballot, and pay from ten to thirty guineas on their admission, and an annual subscription varying from five to ten guineas. The club-houses are, generally speaking, splendid edifices, which add much to the magnificence of the streets and squares in which they are situated.

The latest appropriation of the term *club* has been made by several associations—such as the Roxburgh club of London, the Bannatyne of Edinburgh, and the Maitland of Glasgow—which were formed for the purpose of printing original MSS., which would not otherwise have seen the light, or of rescuing rare productions from oblivion by reprinting them from scarce and valuable editions.

For the political clubs at Athens, see Grote's *History of Greece*, part ii. ch. lxii. The Roman societies answered to our commercial or professionial partnerships. (Smith's *Dictionary of Greek and Roman Antiquities*, art. 'Societas.') [HETÆRIA.]

Socinians. The followers of Socinus, the uncle and the nephew, both of the same name, and celebrated for similar opinions concerning the nature of Christ. The nephew, Faustus Socinus, was the principal founder of the sect. He was an Italian (born at Sienna in 1539), who desired to be admitted into a society of Unitarians already existing in Poland. Their opinions do not appear to have precisely corresponded with his, and admission was refused him; nor did he effect during his lifetime the institution of any distinct congregation; but the views which he disseminated in his writings were gradually adopted by many ministers and religious communities, especially in Poland, where Crellius, Wolgozenius, and others, published a Socinian system of theology, comprised in the *Bibliotheca Fratrum Polonorum.*

Since the death of Socinus, the theologians who have asserted the mere humanity of Christ have been generally denominated Socinians. The doctrines, however, to which that appellation can with strictness be applied are not precisely equivalent to those of the modern Unitarians. The Socinian denies the existence of Christ previous to His birth of the Virgin Mary; he allows, however, that that birth was miraculous, and considers the Saviour as an

object of peculiar reverence and an inferior degree of worship. By the term Mediator, as applied to Christ, he understands that in establishing the new covenant He was the medium between God and man; and of His sacrifice he says that as the Jewish sacrifices were not made for the payment of sins, but for the remission of them, so also the death of Christ was designed for the remission of sins through God's favour, and not for the satisfaction of them as an equivalent. (Mosheim, art. 'Unitarians.')

Sociology (Lat. socius, Gr. λόγος). A word somewhat barbarously coined by the school of M. Comte [Positivism] to express the science which has to do with man in his social capacity; including politics, political economy, and similar subjects.

Sock (Lat. soccus, Ger. socke, allied to *sack*). The name given to the peculiar kind of shoe worn by the ancient Roman comedians; hence used metaphorically for comedy itself. [Buskin.]

Socle (Ital. zoccoli, *a shoe*). In Architecture, a square member, whose breadth is greater than its height; used instead of a pedestal for the reception of a column. It differs from a pedestal in being without base or cornice.

Socratic Philosophy. This term, in its most extensive sense, is used to comprehend the whole developement of Greek philosophy from Socrates to the Neo-Platonists. The title is so far just, as all the schools of this period, with the single exception of the Epicurean, called themselves by the name of Socrates, and arrogated to themselves the merit of exclusively propagating his doctrines. But more strictly it signifies the direction and method which Socrates gave to philosophical enquiry. The earliest philosophers of Greece directed themselves to the study of external nature, grounded always on some deductive theory [Ptolemaic System], which, as the outward condition of man's existence, attracts and constrains his attention, and so becomes the root and source of his intellectual life also. Hence, they were led to form a single and exclusive science—that of universal nature. But on a wider range of observation, the belief in the affinity of man to the powers of the surrounding world was gradually weakened. Philosophy, then, had now arrived at the point where either the distinction of the ethical and the physical must be set forth in clear evidence; or else, by adhering to the previous direction of thought, the light which had been, however unconsciously, kindled must be obscured and extinguished. To admit the claims of both as two conflicting sciences, with equal pretensions to universality, was inconsistent with the unifying tendency of philosophy; and a more scientific range of thought was required, adapted to reconcile and combine their opposite conclusions. Such a view could only be presented by logical or dialectical investigations, which, from the nature of science itself, might show that it is essential to the completeness and perfection of science that it should embrace both nature and reason at once. It is this perception of the unity of science which constitutes the characteristic of Socrates as a philosopher. In all the accounts of him which either Xenophon or Plato furnish, we invariably discern the attempt, at least, to embrace every question within the light of universal science; and to prove that every species of knowledge, if legitimate, can be pointed out and shown to be a necessary member of the general idea of science.

It was not the object of Socrates to establish any perfectly evolved system of doctrine, so much as to awaken by his discourses a new and more comprehensive pursuit of science, which, no longer one-sided and confined to special branches of enquiry, but convinced of its universality, should direct itself to all that is knowable. But beneath this conviction of the universality of science, and the oneness of its object-matter, we distinctly trace that division of the latter into dialectics, physics, and ethics, which his successors more distinctly established. To these heads, therefore, without expressly ascribing them to Socrates, it will be convenient, for the purpose of classification, to refer his several doctrines.

Under the head of *dialectics*, we have, on the testimony of Aristotle (*Met.* xiii. 4), to ascribe to Socrates two of the very first principles of science—the inductive method of proof, and the definition of ideas. [Ethics.] The object which Socrates had in view by the latter was by the definition of ideas, to determine what the thing is in itself, or its essence. As to the former, we are told by Xenophon that when Socrates wished to come to a decision on any point, his investigations proceeded from propositions generally received as true.

Another feature of the Socratic method was to place the particular idea to be examined in a great variety of combinations; a procedure which implied that every particular thought must, if it contain any degree of certainty, maintain its validity under every possible combination. Such was the true Socratic method of dialectics, which derived its name from the *form* of dialogue (διαλέγειν) in which it was accidently worked out; while, on the other hand, the term *Socratic method* has, in modern times, been confined to signify nothing more than this outward form of arguing by question and answer, to the exclusion of its essential characteristics. Socrates, indeed, did not evolve any systematic doctrine of the form and subject-matter of science. He was satisfied with enforcing on his disciples the pregnant truth, that the legitimacy of every branch of knowledge must be tested by its agreement with all others; and that every thought of man must give an account of itself, and have its root in a knowledge of his own and the divine nature.

This knowledge was the end of his physical enquiries, which were based on the general

principle that all the objects of nature are only so far worthy of enquiry as they exhibit traces of intelligence and design. The self-knowledge which the Delphian oracle had enjoined upon him, Socrates held to be impossible, while man is ignorant of the universal principle whence are the issues of all things. In order to oppose the atheism which prevailed in his day, Socrates examined the causes of the existing unbelief, and referred to the proofs of divinity which the wise order of natural things exhibits. As the prevailing scepticism had its origin in the denial of whatever is unseen and imperceptible to the outward senses, he argued that the soul, which is the ruling principle within man, is yet not discernible; but still its existence is admitted, and it participates in the divine nature. Whoever, therefore, can get rid of the weak desire of seeing the Deity under some palpable form, may easily recognise his operations within his own mind, where God has implanted a consciousness of His presence. But he further held, that not only man, but the whole universe, is under the rule of an intelligent governor; that all is formed for some wise end, and affords evidence of that supreme reason from which man's rational soul derives and has its being. In the consideration of individual things, not less than of the universe, the sole question with Socrates was to establish intelligence as the ruling principle of all. This affords no explanation of his low estimate of the existing physiology. His contempt for it was grounded on the same reason as Bacon's aversion for the schoolmen; and he laboured to show that reason is above nature, and that the natural is merely subservient to intellectual ends. Whatever is without reason is contemptible; and the corporeal is of no value except so far as it ministers to the rational soul. Into the nature of the divine essence he did not enquire, but was content with asserting the principle, that the Deity is the supreme reason, and must be honoured by man as the source of all things, and of all phenomena, and of the end of all human endeavours. Lastly, from the divinity within man, the intelligence visible in the universe, and the worthlessness of body, except as an instrument of reason, Socrates deduced the immortality of the soul as a necessary consequence. (Grote's *History of Greece*, part ii. ch. lxviii.; Sir G. C. Lewis *On the Astronomy of the Ancients*, 112, 175, &c.)

Of the actual teaching of Socrates we can form an idea only by a critical comparison of the various accounts left to us by his admirers or disciples. Socrates himself, spending his life in public, and engaged in endless dialectical disputations, wrote nothing, and although the pictures given in the *Memorabilia* of Xenophon and in the Platonic dialogues are in some main features accordant, they exhibit also many points of unlikeness. On the whole, the portrait, as drawn by Xenophon, a man of no profound science or strong imagination, may be regarded as more nearly historical than the pictures presented to us by Plato, the builder up of a vast framework of philosophy, whether systematised or unsystematised. Thus, our nearest information about Socrates comes to us at second hand, and, as generally in such cases, we have stronger grounds for drawing certain negative conclusions than for maintaining a positive position as to the extent of his teaching. Even if it be granted that all the Platonic dialogues in which Socrates is introduced are reports of actual conversations, it is very doubtful whether a deep philosophical meaning is to be sought or was designed to be set forth in all alike. Many of them are professedly designed for the instruction of youths and children, and apparently rather play on the meaning of words than attempt a genuine search for truth whether of facts or ideas. This popular and unscientific character Dr. Whewell has pointed out (*Fraser's Magazine*, April 1866) in the dialogue entitled, *Lysis, or Friendship*, in which Socrates, by playing on various senses in which the word philos, *friend*, is used, seeks to rouse the boy's attention, and by the exaggerated moral that, if we are wise, everybody will trust us with everything, to lead him to the genuine desire of knowledge, the foundation of all virtue. The conversation with Menexenus is of precisely the same kind; and if it is to be called a dialogue of search at all, it is a search simply for the meaning of a word, and not for a real acquaintance with facts, a method by which, in Dr. Whewell's words, 'moral truth never has been obtained.'

There seems to be some historical evidence for the conclusion that some of these unscientific dialogues were published during the lifetime of Socrates. The Platonic dialogue entitled *Meno* seems to be derived from materials furnished by Simon, a harness maker, in whose shop Socrates held frequent disputations. In this conversation, Anytus, the chief accuser of Socrates, is represented as blaming Socrates not for corrupting the Athenian youth (an accusation here confined to the other SOPHISTS), but for charging the most distinguished Athenians with neglecting the education of their sons, 'precisely the topic dwelt upon in Simon's record of Socrates' conversation.' Anytus is also made with a certain good will to advise Socrates to be on his guard, as it was easy to injure a man at Athens—a statement not likely to be published 'after the result of Anytus's accusation had filled all the friends of Socrates with horror.' So, again, in the *Laches*, the Athenian general Nicias, who was put to death in Sicily in B. C. 413, is introduced as taking part in the debate; and in the *Theages* the result of the expedition of Thrasyllus into Ionia, which ended in his defeat in B. C. 406, is spoken of as still uncertain. The conclusion which Dr. Whewell reaches is that several of the shorter dialogues, as the *Laches*, *Charmides*, *Lysis*, *First Alcibiades*, *Rivals*, *Theages*, and *Meno*, were written before his trial, while one, the *Euthyphro*, was written and published during the trial of Socrates.

On the other hand, the belief that the *Apology* is the actual defence made by Socrates

before the dicasts, stands apparently on very slender foundations. Mr. Grote and Dr. Thirlwall hold that it represents the speech really made at his trial, while Dr. Whewell adopts the opinion anciently avowed by Dionysius of Halicarnassus, 'that it is a composition of Plato, intended, indeed, to defend and exalt Socrates, but also to condemn the Athenian people for putting him to death. Dionysius speaks of it as an encomium in the form of an apology, and in proof of his assertion that it 'certainly never saw the door of a court of justice or an assembly of the agora, being written with another purpose,' Dr. Whewell urges that 'the picture of a philosophical life, such as Socrates describes his to have been, seems more likely to have been written by a philosophical disciple like Plato than to have been delivered before a court of justice,' while the detailed reference to the *Clouds* of Aristophanes, a play then twenty-four years old, 'seems to be fitted rather for a literary and philosophical than for a judicial tribunal.' The argument used by Socrates, 'that it is better for everyone to live among good men than bad, and that therefore he could not have willingly tried to make his neighbours bad men, as Meletus accuses him of doing, would not be likely to avail much in the case of a criminal accusation. Finally, in Dr. Whewell's opinion, the prediction with which the apology ends, rather exhibits Plato prophesying what Plato would, than Socrates describing what Socrates had done. The *Crito* both Dr. Whewell and Mr. Grote agree in regarding as a rhetorical composition, and not as the record of a conversation actually held by Socrates between the passing of his sentence and its execution.

Hence, we cannot without great imprudence ascribe to Socrates himself many of the doctrines or opinions put into his mouth by Plato. In the second book of his *Politics*, Aristotle enters into an elaborate refutation of the alleged Socratic position that society should be based on a community of goods, women, and children; but we cannot get further, historically, than the fact that Plato ascribes this theory to Socrates. The same kind of uncertainty, though in a less degree, hangs over the account of the *Daimonion* or heavenly voice, which, it is stated, Socrates had heard even from his childhood, interfering, when he was about to act, in the way of restraint but never of instigation. There is seemingly no evidence that Socrates spoke of this Daimonion as an attendant peculiar to himself, and even according to the representations of his disciples he never spoke of it as anything grand or awful, or entitling him to peculiar deference (Grote, *History of Greece*, part ii. ch. lxviii.), and there is at least room for the conclusion that by the word he signified simply the conscience, in the sense of the divine voice which spoke in the hearts of other men as in his own. But the fact is beyond dispute that Socrates stands alone amongst the citizens of Athens and other Greek states, as having in his mature years abandoned his profession as a statuary, and devoted himself, as one charged with a divine mission, to the task of teaching men, by convincing them of their ignorance, never withholding his conversation from any, and taking reward from none. If his theory that virtue is knowledge states a part for the whole, and contains defects which may naturally give rise to such charges as were actually brought against him, he yet remains, in Mr. Grote's words, 'the first of ethical philosophers, a man who opened to science both new matter, alike copious and valuable, and a new method, memorable not less for its originality and efficacy than for the profound philosophical basis on which it rests.' (*History of Greece*, part ii. ch. lxviii.)

Sod (Dutch zoode). The grassy surface of the soil pared off with a portion of the earth; in other words, turf.

Sod-burning. Burning of turf taken from the surface of worn-out pasture lands for the sake of the ashes as manure, &c.

Soda (Ger. sode, Span. soda, *natron*). *Mineral alkali; sodic oxide.* This substance is the chief oxide of the metal sodium. It may be prepared by heating sodium in contact with dry air, or by placing sodium in contact with fused hydrate of soda. Soda in the hydrated condition is formed when the metal is placed in contact with water: hydrogen is evolved, and the metal fuses by the heat produced. In this operation 23 parts of sodium evolve 1 part of hydrogen, and the solution contains 40 parts of hydrate of soda, which may be obtained in the pure state by evaporating the solution to dryness and fusing the residue. This hydrate contains 1 atom of sodium, 1 of hydrogen, and 2 of oxygen, and cannot be decomposed by heat alone into water and soda. The principal source of sodium compounds is common salt, or chloride of sodium. This compound is found in very large quantities in nature, both in solution in sea-water and in the compact condition as rock salt. To make it available for the manufacture of sodium compounds, it is converted into carbonate of soda by a process invented by Leblanc. The chloride is treated with sulphuric acid by which it is converted into sulphate of soda, hydrochloric acid being evolved, which is condensed in water. [MURIATIC ACID.] The sulphate of soda or salt cake is next mixed with a quantity of small coal and chalk or limestone, and the mixture heated in a reverberatory furnace. The coal reduces the sulphate of soda to the state of sulphide; double decomposition then takes place between the sulphide of sodium and carbonate of lime, carbonate of soda being produced together with sulphide of calcium, which unites with some of the lime from the carbonate, producing insoluble oxysulphide of calcium. The carbonate of soda is next separated from the residue by extraction with water, and from the solution so formed it is obtained crystallised. Carbonate of soda forms large rhombo-prismatic crystals, containing 31

parts of soda, 22 of carbonic acid, and 90 of water. The crystals effloresce when exposed to air, and at about 150° Fahr. they fuse in their water of crystallisation, which may be entirely expelled by the further action of heat. This salt was formerly obtained exclusively from the ashes of marine vegetables, but this source is now entirely superseded by the process of Leblanc. The carbonate is converted into the hydrate of soda by boiling its solution with slaked lime: it is much used in the arts and manufactures. The *sodium salts* are prepared by the action of the respective acids on the carbonate or hydrate of soda. When chlorine is passed into a dilute solution of soda, a valuable disinfectant and bleaching agent, called *eau de Labarracque*, is obtained. Sulphate of soda, or Glauber's salt, forms crystals containing 71 parts of dry sulphate to 90 of water. The crystals effloresce in the air, and the solution exhibits the phenomenon of supersaturation.

The name *soda* is also often incorrectly applied to commercial crystallised carbonate of soda.

Soda Alum. A hydrated sulphate of soda and alumina. It occurs native in fibrous crusts with a glossy internal aspect, about the Solfatara, near Naples [SOLFATARITE]; in the island of Milo; and at St. Juan, near Mendoza, in South America.

Soda Table-spar. A variety of Pectolite found at Kilsyth, in Stirlingshire.

Soda Water. This common beverage is, as usually prepared, a supersaturated solution of carbonic acid gas in water. *Soda water* properly called, consists of one, two, or three drachms of carbonate of soda, dissolved in a pint of water highly impregnated with carbonic acid. This is often a valuable remedy; but it would sometimes be attended by mischievous results, if indulged in to the extent which some persons pursue the use of soda water. The mere aqueous solution of carbonic acid, which is made by forcing the gas into water by a condensing pump, and under a pressure of six or eight atmospheres, is an agreeable and generally speaking harmless diluent.

Sodalite. A silicate of alumina and soda, with chloride of sodium. It generally occurs crystallised in rhombic dodecahedrons, also massive. In Greenland it is found of a green colour: in the Breisgau, massive, of a grey colour in trap rock; at Vesuvius in large white dodecahedral crystals.

Sodium. The metal contained in soda. It is now manufactured on a large scale by submitting an intimate mixture of carbonate of soda and charcoal to a very intense heat in retorts. The sodium distils over, and is run into ingot moulds. Sodium is a silver-white metal, which is soft at ordinary temperatures and melts at 95·6° Fahr. It rapidly decomposes water, and is used for the extraction of aluminium and magnesium.

Sodium-ethyl. A Chemical compound, having intense affinity for oxygen, and containing the radicals sodium and ethyl. Its combination with carbonic acid results in the formation of propionate of soda.

Soffit. [ARCH; LACUNAR.]

Sofi. A Persian word employed to designate religious persons, otherwise termed *dervishes*. It is probably a corruption of the Greek sophos, *wise*. Sofi was the surname borne by the ancestors of the kings of Persia of the race preceding that which now occupies the throne; and Shah Ismael Sofi, the first monarch of that race, also bore it; hence by European writers of the sixteenth and seventeenth centuries it was used erroneously as a title of the king of Persia.

The tenets peculiarly denoted from these persons by the name of Sofism or Sufism are those of a sect which is said to be gaining ground extensively in Oriental countries, especially among the educated classes of Mohammedans. These tenets, like those of the Quietists and other Christian sects of mystics, are founded on a notion of the union of the human soul with the divinity by contemplation and the subjugation of the appetites; but, as has been too frequently the case among Christians also, they have afforded a cover for refined debauchery. The principles of Sufism appear also to have a remarkable affinity, in some respects, with those pantheistic notions which are prominent in the system of the Brahmans, and seem to form the very foundation of the still more widely extended religion of Buddha.

Sofism. [SOFI.]

Soft Coal. A name for the softer kinds of common or pit coal which break with a woody fracture, and of which most of the coals of Derbyshire and Staffordshire are composed. The term *soft coal* is also synonymous with CHERRY COAL.

Softening. In Painting, the blending of colours into each other. [SFUMATO.]

Soil (Fr. sol, Lat. solum). Earthy and other substances in a state of mixture with organised matter fit for the growth of plants. The surface of the earth in every country on which plants have grown and decayed is properly denominated *soil*; while the earth at a foot or more beneath the surface, commonly called *subsoil*, is comparatively without organised matter, and is therefore properly denominated earth, clay, sand, gravel, lime, or mixed earth, rocks, or stones, as the case may be.

Soirée (Fr. *evening*). This term, originally given by the French to certain evening parties held for the sake of conversation only, has been since introduced into all the languages of modern Europe, and is now employed as a common designation of evening parties in which ladies and gentlemen are intermixed, whatever be the amusements introduced. It is frequently applied in England to the public meetings of certain societies held for the advancement of their respective objects, at which refreshments are dispensed during the intervals of business.

Soke (A.-Sax. soc). A territorial division, now subsisting in Lincolnshire. This term, according to the etymology given by Bracton, designated a precinct in which a particular lord exercised justice. [SOCAGE.]

Sol. In Heraldry, anciently used to denote *or* in emblazoning arms.

SOL. In Music, the French and Italian name for the note of the gamut corresponding to our G.

Sol in its Splendour. In Heraldry, when the sun is figured, i.e. delineated with a human face, and surrounded with rays.

Solanaceæ (Solanum, one of the genera). A natural order of herbaceous or shrubby perigynous Exogens, inhabiting all parts of the world excepting the Arctic regions. They are chiefly known from *Scrophulariaceæ* by their curved or spiral embryo, the plaited æstivation of their flowers, and by the flowers being usually regular, with the same number of stamens as lobes. The first of these characters, however, is not of universal importance; the plaited corolla and symmetrical flowers are better marks of distinction. This order contains Nightshade, Henbane, Mandrake, Tobacco, Stramonium, the Potato, and the Tomato, the leaves of all which are narcotic and exciting, but in different degrees, from *Atropa Belladonna*, which causes vertigo, convulsions, and vomiting, tobacco, which will frequently produce the first and last of these symptoms, henbane and stramonium—down to some of the Solanum tribes, the leaves of which are so inert as to be used as kitchen herbs. Even in the potato plant, the narcotic acrid principle is found in the stem and leaves, and in the rind of the tuber; but the principal part of the latter consists of starch, and the small quantity of deleterious matter being volatile and near the surface, is readily driven off by the heat used in cooking. They are distinguished in the Solanal alliance by their five free stamens, axile placentæ, and terete embryo.

Solania. The active principle of the *Solanum Dulcamara*, or Woody Nightshade, and other species of *Solanum*; it is the ingredient which renders greened potatoes deleterious, being formed in the tubers by the action of light. It is a white alkaloid substance, insoluble in water, but soluble in alcohol, and is highly poisonous, one grain dissolved in dilute sulphuric acid having been found sufficient to kill a rabbit in six hours. Its combinations with the acids are bitter. It is also called *Solanine* or *Solanina*.

Solanine. [SOLANIA.]

Solano. A hot oppressive wind which occasionally blows in the Mediterranean, and particularly on the eastern coast of Spain. The solano is a modification of the sirocco.

Solanum (Lat. *nightshade*). A very extensive genus of plants typical of the *Solanaceæ*. They comprise plants of most varied aspect, some weedy, others ornamental, and some few useful. Some are herbs, some shrubs, and some small trees with lateral or terminal inflorescence. The inflorescence, indeed, in the first instance is always terminal, but in course of growth it becomes bent downwards to give place to a shoot, which is given off from the side of the stem lower down, so that there is a reciprocal change in the direction of the shoot and of the inflorescence. In this way the seeming anomaly of an inflorescence placed on the side of the main stem, and not axillary to a leaf (frequently not even opposite to one), may be explained.

The most important species is *S. tuberosum*, the well-known Potato, of which the underground stems or tubers are in general use as an esculent. They are to be met with everywhere in Europe, and form a principal part of the food of a large proportion of its inhabitants. The plant is regarded as indigenous to Chili and Peru. Its introduction into Europe is ascribed to certain colonists sent from this country to Virginia in 1586, under the auspices of Sir Walter Raleigh. Some authors, indeed, affirm that it was first introduced into Europe by Sir John Hawkins, in 1545; others, that it was introduced by Sir Francis Drake, in 1573; while others, again, maintain that it was for the first time brought to England from Virginia by Sir Walter Raleigh, in 1586. But this discrepancy seems to have arisen from confounding the common Potato (*Solanum tuberosum*) with the Sweet Potato (*Batatas edulis*). The latter was introduced into Europe long before the former, and it seems most probable that it was the species brought from New Granada by Hawkins. Sweet potatoes require a warm climate, and do not succeed in this country; they were, however, imported in considerable quantities, during the sixteenth century, from Spain and the Canaries, and were supposed to have some rather peculiar properties. The kissing comfits of Falstaff, and such like confections, were principally made of batatas and eringo roots. There is reason to think that we are really indebted for the Potato (as well as for tobacco) to Sir Walter Raleigh, or the colonists whom he had settled in Virginia. Gerarde, an old English botanist, mentions in his *Herbal*, published in 1597, that he had planted the Potato in his garden at London about 1590; and that it succeeded there as well as in its native soil, Virginia, whence he had received it. Potatoes were at first cultivated by a very few, and were looked upon as a great delicacy. In a manuscript account of the household expenses of Queen Anne, wife of James I., who died in 1618, and which is supposed to have been written in 1613, the purchase of a very small quantity of potatoes is mentioned at the price of 2*s.* a pound. The Royal Society, in 1663, recommended the extension of their cultivation, as a means of preventing famine; but down to the year 1684 they were raised only in the gardens of the nobility and gentry. In that year they were planted, for the first time, in the open fields in Lancashire—a county in which they have long been very extensively cultivated.

Potatoes, it is commonly thought, were not introduced into Ireland till 1610, when a small quantity was sent by Sir Walter Raleigh, to be planted in a garden in his estate in the vicinity of Youghal. Their cultivation extended far more rapidly than in England; and they have long furnished from three-fifths to four-fifths of the entire food of the people of Ireland! Potatoes were not raised in Scotland, except in gardens, till 1728, when they were planted in the open fields by a person of the name of Prentice, a day labourer at Kilsyth, who died at Edinburgh in 1792.

The extension of the Potato cultivation has been very rapid during the last half-century. The quantity now raised in Scotland is supposed to be from ten to twelve times as great as the quantity raised in it at the end of the American war; and though the increase in England has not been nearly so great as in Scotland, it has been greater than during any previous period of equal duration. The increase on the Continent has been similar. Potatoes are very largely cultivated in France, Italy, and Germany; and, with the exception of the Irish, the Swiss have become their greatest consumers. They were introduced into India some sixty or seventy years ago, and are now successfully cultivated in Bengal; they have also been introduced into the Madras provinces, Java, the Philippines, and China. But the common potato does not thrive within the tropics, unless it be raised at an elevation of 3,000 or 4,000 feet above the level of the sea, so that it can never come into very general use in these regions. This, however, is not the case with the sweet potato, which has also been introduced into tropical Asia; and with such success, that it already forms a considerable portion of the food of the people of Java, and some other countries. So rapid an extension of the taste for, and the cultivation of, an exotic, has no parallel in the history of industry: it has had, and will continue to have, the most powerful influence on the condition of mankind.

The Potato consists of a mass of cells, enclosing starch-granules and an albuminous juice. The chemical composition of the Potato is subject to great variations, as the analyses of different chemists vary considerably. In general terms, it may be stated that Potatoes contain water in quantity amounting to three-fourths of their weight, the remaining fourth part being made up of starch, gum, sugar, albumen, vegetable fibre, and a very small proportion of fatty material. Potatoes in cultivation are subject to various diseases, the most important and disastrous of which is one which first made its appearance (at least as a widely spread malady) in 1845. This potato-murrain appears, from the researches of the Rev. M. J. Berkeley and others, to be due to the presence of a fungus, *Botrytis* (or *Peronospora*) *infestans*, which first attacks the leaves, causing a discoloration of them, and thence rapidly spreads down the stems to the tubers. The principal effects of the disease consist in the increased quantity of water, the diminished quantity of starch, and the conversion of the albumen into casein. Owing to the almost entire dependence of the Irish peasantry on this vegetable for food, the most disastrous consequences ensued from the failure of this crop; and it is still heartily to be wished that one of a less precarious nature should be grown, and one which would furnish a larger percentage of nutritious matter than the Potato. Numerous substitutes have been proposed and tried, but time is required to combat the prejudice in favour of the Potato, and to develope sufficiently the capabilities of the proposed substitutes.

Potatoes furnish a large quantity of starch, which is employed for various purposes in the arts. It forms the basis of certain farinaceous foods, as Bright's Nutritious Farina, &c., and is mixed with wheaten flour in the manufacture of bread. This adulteration can readily be detected by the microscope, especially on the addition of a solution of potash, which causes the starch granules of the potato to swell up, while no effect is produced on the starch-grains of wheat. From potato-starch is also procured a substance analogous to gum, called *dextrine*, and which is employed as a substitute for gum, size, and paste. The pulp of the Potato, after the extraction of the starch, becomes hard and horny when dried, and is used in the manufacture of snuffboxes, &c. Raw potatoes scraped are used as a popular cooling application to burns and scalds. From Potatoes a coarse-tasted brandy is prepared in large quantities on the Continent. The stem and leaves have slightly narcotic properties, on which account the extract from them has been employed as a narcotic to allay pain in cough and rheumatism, &c. Potatoes when decaying have been stated to emit a phosphorescent light, but this requires confirmation. As a vegetable, the Potato is excellent in whatever way it may be dressed—whether plain boiled, steamed, fried, or roasted. With the flour of potatoes puddings and cakes have been made; starch has also been obtained, which for purity and nutritive properties is very little inferior to arrowroot. The usefulness of the potato was remarkably shown by M. Parmentier, who did so much in France to promote its cultivation towards the end of the last century, and who gave a grand entertainment, at which Benjamin Franklin, Lavoisier, and many other celebrated men of that day were present. Every dish consisted of potatoes dressed in an endless variety of form and fashion; and even the liquors were the produce of this precious root.

S. esculentum and its varieties furnish the fruits known as Aubergines, which are highly esteemed in France, and may occasionally be met with in Covent Garden Market; they are of the size and form of a goose's egg, and usually of a rich purple colour. The Egg-plant, which has white berries, is only a variety of this. The Peruvians eat the fruits of *S. muri-*

catum and *S. quitense*; those of *S. ramosum* are eaten as a vegetable in the West Indies. The Tasmanian Kangaroo Apple is the fruit of *S. laciniatum*; unless fully ripe, this is said to be acrid. In Gipps' Land, Australia, the natives eat the fruits of *S. vescum*, which, like the preceding, is not agreeable till fully ripe, when it is said to resemble in form and flavour the fruits of *Physalis peruviana*. The fruits of *S. album* and *S. æthiopicum* are used in China and Japan. Those of *S. Anguivi* are eaten in Madagascar. Of other species the leaves are eaten: as those of *S. oleraceum* in the West Indies and the Feejee Islands, of *S. sessiliflorum* in Brazil, of *S. nigrum* in the Islands of Bourbon and Mauritius, &c.

Some species are employed as dyes. Such is *S. indigofera*, cultivated in Brazil for the sake of its indigo. The juice of the fruit of *S. gnaphalioides* is said to be used to tint the cheeks of the Peruvian ladies, while their sisters of the Canary Isles employ for a similar purpose the fruits of *S. Vespertilio*. The fruits of *S. saponaceum* are used in Peru to whiten linen in place of soap. *S. marginatum* is employed in Abyssinia for tanning leather. [LYCOPERSICUM.]

Solar. In Mediæval Domestic Architecture, a chamber built over the cellar at the back of the daïs of the great hall, or, in later buildings, over the hall itself. (*Domestic Architecture in England from Richard II. to Henry VIII.* part i. ch. iii.)

Solar Cycle. A period of twenty-eight years. [CYCLE.]

Solar Phosphori. Substances which are seen to be luminous in a dark place after having been exposed to light. Calcined oyster shells are a good example.

Solar System. The Solar System, in Astronomy, consists of the sun, and all the celestial bodies whose motions are controlled by its gravitation, viz. the planets, satellites, and comets. Under the words ASTRONOMY; COMET; COPERNICAN SYSTEM; HELIOCENTRIC SYSTEM; METEORS, LUMINOUS; PLANET; PTOLEMAIC SYSTEM; SATELLITE; and SUN; we have referred to the different explanations of celestial phenomena, which have been given from time to time, and have entered into details regarding the different bodies of which our system is composed. We may regard that system from the most general point of view, as a type of those which probably are feebly indicated to us in the light of every star; and now that the complete similarity of our sun to the other bodies of the sidereal universe in the broader physical features has been established by the spectroscope, the mind without difficulty seizes the idea. The dimensions of our sun are enormous merely in consequence of its proximity to us, and if it be not a coloured star it is probably a variable one. We may fairly assume, therefore, that other systems are not vastly dissimilar from our own, except perhaps in the life conditions which obtain at the present epoch. The number of bodies which compose the system as at present known is as follows:—

1. The central Sun—the primary.
2. Ninety-three planets, including eighty asteroids.
3. Eighteen satellites or tertiary bodies.

The sun and planets will be found elsewhere described. The minor planets which circulate between Mars and Jupiter are as follows (arranged in the order of discovery):—

1	Ceres	45	Eugenia
2	Pallas	46	Hestia
3	Juno	47	Aglaia
4	Vesta	48	Doris
5	Astræa	49	Pales
6	Hebe	50	Virginia
7	Iris	51	Nemausa
8	Flora	52	Europa
9	Metis	53	Calypso
10	Hygieia	54	Alexandra
11	Parthenope	55	Pandora
12	Victoria	56	Melete
13	Egeria	57	Mnemosyne
14	Irene	58	Concordia
15	Eunomia	59	Olympia
16	Psyche	60	Echo
17	Thetis	61	Danaë
18	Melpomene	62	Erato
19	Fortuna	63	Ausonia
20	Massilia	64	Angelina
21	Lutetia	65	Maximiliana
22	Calliope	66	Maia
23	Thalia	67	Asia
24	Themis	68	Leto
25	Phocea	69	Hesperia
26	Proserpine	70	Panopea
27	Euterpe	71	Niobe
28	Bellona	72	Feronia
29	Amphitrite	73	Clytie
30	Urania	74	Galatea
31	Euphrosyne	75	Eurydice
32	Pomona	76	Freia
33	Polyhymnia	77	Friga
34	Circe	78	Diana
35	Leucothea	79	Eurynome
36	Atalanta	80	Sappho
37	Fides	81	Terpsichore
38	Leda	82	Alcmene
39	Lætitia	83	Beatrix
40	Harmonia	84	Clio
41	Daphne	85	Io
42	Isis	86	Semele
43	Ariadne	87	Sylvia
44	Nysa	88	Thisbe

Other integral portions of the system are the meteoric rings lying near the earth's orbit

[METEORS, LUMINOUS], and possibly others, the existence of which is suspected in other portions of the system. [COMET; ZODIACAL LIGHT.]

Both physicists and geologists are now agreed that the earth was once in an incandescent state, a condition of things probably represented to us at the present time, in kind if not in degree, by our sun. We are therefore justified in assuming that the rest of the planetary family were once in the same condition; hence it is extremely unlikely that, taking their masses and positions into consideration, they present at the present time the same life conditions as the earth. The verdict of the telescope is precisely in the same direction. Hence much that has been advanced without taking these facts into consideration will require to be modified in the light of modern enquiry.

It is difficult to accept the present terrestrial conditions as merely *accidental*, but if it can no longer be doubted that our globe was once an incandescent body and a sun pro tanto, so also a time will come when, as a remote consequence of the further dissipation of its energy, it will again become unfit for the abode of beings similar to those which now inhabit it. If we accept the evidence furnished by the other planets, we are almost driven to this conclusion. Jupiter and Saturn may be worlds —as far as life conditions are concerned— younger than our own. Life conditions on Mars we know to be not very unlike our own, if we except gravity; while, according to Frankland, the moon has lost all its internal heat, and probably has exhausted the cycles of life on its surface.

The celestial scenery presented by the different planets is vastly different. The inhabitants of the earth with its one moon, which lights up but a small per-centage of our nights, can scarcely form an idea of the astounding grandeur of the scene that is unfolded in some of the sister planets, from moonless Mercury, with a sun occupying a large portion of the celestial arc, to Neptune, where the same body appears only as a star. Among these various systems, however, that of SATURN stands pre-eminent in its gorgeousness and uniqueness. Not only have we here eight moons performing their circuits in intervals varying from twenty-two hours to seventy-nine days, but a ring system which may possibly consist of millions of satellites in the closest juxtaposition—asteroidal rings capable of reflecting the sun's light, spanning the heavens, now in a complete arch through the zenith, now in a broken one near the horizon, the varying appearances depending upon the latitude of the observer and the position of the planet's shadow on the ring. These same rings give rise to most curious eclipse phenomena. Not only do they at night eclipse the stars, but in certain latitudes they cause eclipses of the sun. 'In latitude 40° we have morning and evening eclipses for more than a year, gradually extending until the sun is eclipsed during the whole day, and then total eclipses continue for nearly 7 years, eclipses of one kind or another taking place for 8 years 292·8 days.'

The celestial scenery in the solar system is, however, in spite of all its variety, vastly inferior to that afforded by the systems which in all probability circulate round the various multiple systems, some of which consist of stars of colours sufficiently distinct to give rise to days of different colours.

Solar Year. The interval between the sun's leaving the first point of Aries and returning to it again.

Soldan. [SULTAN.]

Solder (Fr. souder, from Lat. solidus, *solid*). Plumbers' solder is an alloy of three parts of lead and one of tin; it is more fusible than lead, and readily adheres to clean surfaces of that metal when it is fused. Fine solder is a mixture of two parts of tin and one of lead; it fuses at 360°. Hard soldering, or brazing, by which two surfaces of copper are made to adhere, is done by fusing together brass and zinc. When this solder is used, the copper requires to be highly heated.

Soldier (Low Lat. soldarius; literally, *one who serves for pay*). [SOU.] In general language, a person equipped and maintained by the state for the purpose of defending it from foreign aggression, of putting down intestine commotion, or, in short, of protecting its interests either at home or abroad, according to instructions issued by the existing government. [ARMY; ENLISTMENT, &c.]

Sole of an Embrasure. In Fortification, the bottom of an embrasure.

Sole Piece. In the cradle on which a ship is launched, the sole piece is a plank resting on the bilgeways, and sustaining the lower ends of the poppets on which the weight of the vessel hangs. These poppets have tenons in their lower ends which fit into a groove in the sole piece.

Sole Plate. A strong plate of iron which constitutes the base or foundation of a marine engine, and which is securely bolted to the keelsons of the ship, while the various parts of the engine are bolted to it. In side-lever marine engines the condenser is usually cast upon the sole plate, so as to obviate the necessity of joints in a part of the engine very liable to air leaks.

Solea (Lat.). In Architecture, that part of the Roman basilica which answers to the presbytery in more modern churches.

SOLEA. In Mammalogy, the inferior surface of the foot or hoof.

SOLEA. The name of a genus of flat fishes (*Pleuronectidæ*), characterised as follows: 'Both eyes on the right side; the mouth distorted on the side opposite the eyes; small teeth in both jaws, but confined to the under side only; form of the body oblong; dorsal and anal fins extending to the tail.' The common sole (*Solea vulgaris*, Cuv.) is taken by trolling, and in enormous quantities, along our coasts, principally from Sussex to Devon-

shire; and excepting towards the latter end of February, and the beginning of March, when the soles are spawning and are rather soft and watery, they are in good condition for the table throughout the year.

Solecism (Gr. σολοικισμός, said to be derived from Soli, an Athenian colony in Cilicia, whose inhabitants spoke a barbarous Greek). In Grammar and Rhetoric, a violation of the idiomatic rules of grammar or construction in writing or speaking a language. Quintilian distinguishes *solecism* from *barbarism*, the latter word being applied to the erroneous use of single words.

Solenaceans (Gr σωλήν, *a tube*). The name of a family of Dimyary Bivalve Molluscs, of which the razor shell (*Solen*) is the type; they are distinguished by the great length of the respiratory tubes, whence their name.

Solenoid (Gr. σωληνοειδής, *like a tube*). In Electro-Dynamics, a name given by Ampère to a system of small electrical currents, equal and equidistant, and returning into themselves, the planes of which are normals to any given line, whether a straight line or curve, upon which their centres are situated, and which forms the axis of the *solenoid*. (Despretz, *Traité de Physique*, 1836.)

Solfatara. A volcanic vent from which sulphur and sulphurous and other acid vapours and gases are erupted with much steam.

Solfatarite. A name given to the Soda-alum found at Solfatara near Naples.

Solfeggio. In Music, the system of arranging the scale by the names *ut, re, mi, fa, sol, la, si*, by which musical students are taught to sing, these notes being represented to the eye by lines and spaces, to which the syllables in question are applied. [MUSIC.]

Solicitor. The professional designation of persons admitted to practise in the Court of Chancery in the conduct of suits, &c., who are styled *attorneys* in the courts of common law. [ATTORNEY.] In Scotland, the term *solicitor* is synonymous with *attorney* in England. They are inferior to the *writers to the signet*, and practise in the inferior courts.

Solicitor-General. The *solicitor-general* is an officer of the crown, who holds by patent, and ranks next to the attorney-general, with whom he is, in fact, associated in the management of the legal business of the crown and public offices. He receives some particular fees on pleadings, and on the enrollment of patents, &c.; but the division of business between him and the attorney-general is chiefly regulated by usage founded on convenience. The earliest date at which the name of this officer occurs, so far as is known, is the year 1461. [ATTORNEY-GENERAL.]

Solid (Lat. solidus). In Geometry, a magnitude which has three dimensions—length, breadth, and thickness. The boundaries of solids are *surfaces*, which have only two dimensions—length and breadth; the boundaries of surfaces, again, are *lines* which have but one dimension, length. Lastly, the extremities of lines are *points* which are destitute of all dimensions, and possess position merely.

SOLID. In Physics, the term *solid* is applied to that condition of matter in which the attractive forces of the molecules are greater than the repulsive, and the molecules consequently cohere with greater or less force. The other states of matter are the *liquid*, in which the attractive and repulsive forces are nearly balanced; and the *gaseous*, in which the repulsive prevail.

Solid Angle. In Geometry, an angle formed by the meeting in one point of three or more plane angles, which are not in the same plane. This is Euclid's definition. [ANGLE.] A solid angle may be measured by the area of spherical polygon which it determines on a sphere of unit radius, whose centre is at its vertex. By allowing the plane angles to increase in number and diminish in magnitude, we may extend the conception of a solid angle to that which is formed at the vertex of every cone.

Solid Bodies, Flow of. The thin tubes of block tin, used by painters for holding their colours, are formed by placing a disc of block tin in a die or hollow cylinder, into which cylinder a punch that almost exactly fits it is forced down by appropriate mechanism, and the tin rises into the intervening annulus in the same way as if it were a liquid, its constituent particles being made to move upon one another by the great pressure applied, in much the same way as they would do if the tin were melted by heat. Recently the subject of the flow of solid bodies by the application of great force has been experimentally investigated by M. Tresca; first, by punching a cylindrical hole in a plate; secondly, by the compression of a cylinder in a direction parallel to its axis; and, thirdly, by compelling the efflux of solid materials from a cylindrical chamber through an orifice in the side or bottom. In the ordinary flow of liquids, the compelling force is gravity, which, however, is not sufficient to move the particles of all bodies upon one another. But there is no reason to doubt that solids equally with fluids will be made to conform to hydrostatic laws, if instead of gravity we use some other force which shall be proportionate in amount to the resistance which has to be overcome.

The first experiment of M. Tresca was made in punching a block of lead, composed of sixteen plates superimposed on one another. The plates were four millimètres, or about one-sixth of an inch, in thickness, their total height being sixty-four millimètres, or about two and a half inches. They were firmly held together by iron plates at the top and bottom, in each of which plates a hole of twenty millimètres was made, through which a punch of that diameter could pass. The punch was propelled through the lead by hydraulic power, and a punching was extruded of twenty millimètres diameter and thirty-one millimètres high. Now, as it was found that the specific

gravity of the lead punched out had not been changed, the question arose, what became of the other thirty-three millimètres in the height of the column? To determine this, the punched block was cut through, and the cut surface carefully planed; and it was found, that while the top layer and the three bottom ones retained their original thickness, the thickness of the intermediate layers was considerably reduced, and it appeared that much of the metal in the early part of the punching escaped sideways, in a way similar to that in which a liquid would escape, that being the line of least resistance during the early part of the operation.

It was further found, on examining a section of the punching by a microscope, that the punching of each succeeding plate was dished over the preceding one, so that the dished edges of the whole sixteen layers could be traced from top to bottom of the punching only vastly reduced in thickness. In punching layers of wrought-iron plates, similar results have been observed.

M. Tresca's second experiment consisted in the compression of a cylindrical block of lead, 60 centimètres diameter, formed by placing twenty discs upon one another, the collective height being 63 millimètres. The block was compressed until its height became 18 centimètres; and its diameter was then found to be increased to 110 millimètres in the middle of the block, and 103 and 105 millimètres at the ends. It was found on examination that the upper and lower plates had hardly changed their dimensions, whereas the middle plates had not only become thinner but had dished themselves outwards so as to enclose the others and to form the exterior surface of the block.

M. Tresca next subjected two circular plates of lead 3 millimètres thick and 4 inches diameter to compression between two iron discs, one of which had a hole ·8 inch diameter in its centre. In all those parts of the plates pressed by the iron disc, they were reduced by compression to ·08 in thickness, and the lines of the layers were parallel in this part. The lead flowed out both by the circumference and through the central hole in a jet of metal which assumed the figure of the contracted vein, but the jet instead of being solid was hollow, a result imputed to the circumstance that the particles are acted on by two forces, the one being hydrostatic pressure and the other cohesion. M. Tresca has subjected to mathematical investigation the laws proved by his experiments to be in operation in regulating the flow of solids under compression, and has deduced formulæ which represent the facts with accuracy, and which constitute the elements of a new theory of the strength or resistance of materials. The processes of planing and turning, cutting, hammering, and rolling, and, in fact, nearly all the mechanical processes for moulding materials practised in the arts, are illustrations of the principle which M. Tresca has brought to light, and which appears destined to overturn some of the accepted foundations of some departments of physical science.

Solid Problem. A solid problem formerly denoted one which could not be constructed by the intersections of circles and straight lines, but whose geometrical construction required the description of one or more conic sections. The algebraic solution of a solid problem leads to a cubic or biquadratic equation. Problems which admitted of being constructed by the intersection of two circles, or of a straight line and circle, were called *plane problems*; they give rise to equations of the second degree.

Solidity (Lat. soliditas). Like many other mechanical terms, this term is not easily defined with exactness. Fortunately, its popular definition is unnecessary, inasmuch as everyone must be familiar with the particular condition of matter to which it is applied. It occurs when the cohesion of particles of matter is so great that mere gravity is insufficient to cause them to move freely over one another, as is the case in liquids and gases.

Solidungulates (Lat. solidus, and ungula, *a hoof*). The name of a tribe of Mammals, including those with only a single hoof on each foot: as the horse, ass, &c.

Solifidian (Lat. solus, *alone*, and fides, *faith*). A name sometimes applied to those who maintain that men are justified by faith only without reference to works.

Soliloquy. [Monologue.]

Solipeds. [Solidungulates.]

Solitaries. [Anchorites; Hermits.]

Sollecito (Ital. *anxious*). In Music, a term denoting that the movement to which it is affixed is to be performed in a mournful manner. It also means that the music is to be performed carefully.

Solo (Ital. *alone*). In Music, a movement, or part of a movement, in which only one voice or instrument is employed or is especially prominent.

Solomon's Seal. The common name of the *Convallaria polygonatum*, sometimes made the type of a distinct genus, *Polygonatum*.

Solstice (Lat. solstitium). The time at which the sun is at its greatest distance from the equator, and when its diurnal motion in declination ceases. This happens at midsummer and midwinter; or when the sun arrives at the tropic of Cancer and the tropic of Capricorn.

Solstitial Points. Those points of the ecliptic at which the sun arrives at the time of the solstices. They are the first points of Cancer and Capricorn.

Solution (Lat. solutio, from solvo, *I loose*). The force which binds similar masses of matter together is called *cohesion*, that which binds dissimilar masses being termed *adhesion*. When a solid is placed in a liquid, solution results if the adhesion of the solid for the liquid is greater than the cohesion existing among the particles of the solid; but if the cohesion is superior to the adhesion, then the solid is said

to be insoluble. Heat is antagonistic to cohesion, to a far greater extent than it is to adhesion; hence heat generally facilitates solution. When heat is withdrawn from a body, the opposite effect of course takes place; and this explains how crystals and other solid bodies separate out from a hot solution on cooling. A *saturated* solution results when cohesion and adhesion exactly balance each other.

SOLUTION. In Mathematics, the construction of a proposed problem, or the expression of its conditions by an equation which gives the value of the unknown quantity.

Solvent. In Chemistry, the liquid in which a solid is dissolved. The substance dissolved is sometimes distinguished as the *solvend*.

Sombrerite. A new mineral (a phosphate of alumina and lime) remarkable for the large amount of phosphoric acid which it contains. It forms a large portion of some small islands in the West Indies, especially of Sombrero Island, about sixty miles from St. Thomas.

Sombrerite has been used for the preparation of phosphorus and phosphoric acid, and also for the manufacture of artificial manure (superphosphate of lime) for agricultural purposes.

Somervillite. A variety of Melilite, of a dull yellow colour, found in the older ejected lavas on Vesuvius, associated with black mica, &c. It was named by Brooke after Dr. Somerville.

Sommite. A name for Nepheline, given from its occurrence at Monte Somma.

Somnambulism (Lat. somnus, *sleep*, and ambulare, *to walk*). This is a species of dreaming, in which the bodily as well as the mental functions are affected. There are many remarkable cases of this kind on record, some of which would appear perfectly incredible, were they not attested by creditable as well as by competent and scientific witnesses. Somnambulism has been defined as 'a state in which the mind retains its power over the limbs, but possesses no influence over its own thoughts, and scarcely any over the body, excepting those particular members of it which are employed in walking.' Dr. Abercromby, in his *Inquiries concerning the Intellectual Powers and the Investigation of Truth*, observes, in regard to this singular affection, that although the mind is fixed upon its own impressions as in ordinary dreaming, the bodily organs are more under the control of the will; so that the individual acts under the influence of his erroneous conceptions, and holds conversation in regard to them. He is also, to a certain degree, susceptible of impressions from without through his organs of sense; not, however, so as to correct his erroneous impressions, but rather to be mixed up with them. Dr. Abercromby observes, that the first degree of somnambulism generally shows itself by a propensity to talk during sleep; the person giving a full and connected account of what passes before him in dreams, and often revealing his own secrets or those of his friends. Walking during sleep is the next degree, and that from which the affection derives its name. He gets out of bed, often dresses himself, and goes out of doors, walks frequently over very dangerous places in safety; sometimes he gets out of a window, walks along a parapet, gets to the roof of a house, and returns through similar risks to his apartment. On awaking in the morning he is either utterly unconscious of having stirred during the night, or remembers it as a mere dream. These cases are comparatively common; but sometimes the transactions of the somnambulist are carried much further: he will mount his horse and ride, or go to his usual occupations, such as threshing, saddle-making, playing on musical instruments, composing verses, and so forth.

Although somnambulists are generally insensible to anything that is said to them, they are sometimes capable of holding conversation, especially in those cases where the affection occurs, as it sometimes does, in the daytime. In these attacks the individuals are generally unconscious of external impressions, or at all events extremely confused in their notions of external things. They frequently speak intelligibly, holding conversations with imaginary beings, or relating circumstances which were supposed to have been entirely unnoticed or forgotten. Some have been known to sing in a style superior to anything which they could attain when awake; and Dr. Abercromby states that there are some well authenticated instances of persons in this condition expressing themselves correctly in languages with which they were imperfectly acquainted.

Somnus (Gr. Ὕπνος). In Mythology, the god of sleep, the son of Erebus and Nox, or of Nox alone, and brother of Thanatos, *death*. [SARPEDON.]

Son Assault Demesne (Old Fr.). In Law, a plea in an action for an assault, viz. that it was the plaintiff's own original assault that occasioned the violence complained of.

Sonata (Ital. sonare, *to sound*). In Music, an instrumental composition, usually containing three movements, an allegro, a slow movement, and a rondo. Modern sonatas are generally for one or two instruments only, as for the pianoforte, or for the piano and violin.

Sonnet (Ital. sonetto). In Poetry, a short composition of fourteen or fifteen lines, of ten or eleven syllables, rhymed according to an intricate but not always precisely similar arrangement. It is the oldest form in which the Italian language was used; but it was, at a still earlier period, employed, although not commonly, by the Provençal poets. In Italy, Dante and the Tuscan poets his contemporaries brought the sonnet into public estimation, about the beginning of the fourteenth century; but by them it was invariably employed as the vehicle of thoughts wrapped in very obscure language, and probably of a symbolical nature, though generally, in their outward signification, breathing the spirit of romantic and chivalrous love. By Petrarch, in the course

of the same century, the sonnet was carried to perfection in point of form and polish; although applied by him, as it had been by his predecessors, almost exclusively to the subject of his figurative and mystical passion. Since the time of Petrarch the sonnet has been a favourite form of composition in Italy, especially for the purposes of occasional poetry. In France it has had little success; or rather the French sonnet is a different poem, less regular in its construction than the Italian. In England, Milton has given to it a dignity peculiarly his own, together with much of the melody and tenderness which characterises his Italian models. The proper sonnet is divided into two quatrains, with four lines and two rhymes each, and two terzines, each with three lines and a single rhyme. Pieces of a similar metrical structure in octo-syllabic lines are termed by the Italians Anacreontic sonnets. It is sometimes said that there is 'hardly an educated Italian who has not composed a sonnet.'

Sonnites. [SHIAH.]

Soot (A.-Sax. sot). This well-known chimney deposit consists chiefly of fine particles of carbon mechanically carried up from a coal or wood fire. It also contains much mineral matter, the lighter portion of the ash of the fuel; and in addition always yields liquid hydrocarbons, condensed doubtless from unburnt hydrocarbon vapours, together with notable quantities of ammoniacal salts. The latter render soot, especially coal-soot, valuable as a manure.

Soot Coal. A variety of bituminous coal with an uneven earthy fracture. It is found in Scotland.

Soothsayers. [ASTROLOGY; DIVINATION; ORACLE.]

Sophism. [FALLACY.]

Sophist (Gr. σοφίστης, from σοφός, *wise*). A Greek word, originally signifying a person of talent and accomplishments. It was applied to a class of men who arose in Greece in the fifth century B.C., and taught the youth in the principal cities various arts and acquirements for hire. It has hence come to be the general designation of all such as cultivate any branch of science or philosophy with a view to outward advantages, careless of the truth of what they advance, except in so far as it may contribute to those purposes. The first Greek who assumed the name of *Sophist* was Protagoras, a native of Abdera, who flourished about the year 440 B.C., and obtained numerous pupils and auditors, especially in Athens. Of those who followed the same occupation, the most celebrated were Hippias of Elis, Gorgias of Leontium, Prodicus of Ceos, and Euthydemus of Chios, with his brother Dionysiodorus. None of the writings of these men have survived; but we have abundant notices in the writings of their contemporaries, especially Plato, Xenophon, and Aristophanes, of the character of their teaching. On that teaching very different opinions have been entertained; but it is a subject on which a more than ordinary attention to both sides of the controversy is absolutely necessary. Mr. Grote, in his *History of Greece*, part ii. ch. lxvii., has impugned altogether the assertion, that the Sophists were selfish teachers who systematically corrupted the Athenian youth, and maintains that Solon and Pythagoras, Socrates, and even Plato himself were ranked in this class by their contemporaries. He denies that any charge of corruption is brought against Protagoras by Plato, whose opposition to the paid teachers arose 'from the radical difference between his point of view and theirs. He was a great reformer: they undertook to qualify young men to doing themselves credit and rendering service to others in active Athenian life. Plato was also unrivalled as a speculative genius and as a dialectician: and his reforming as well as theorising tendencies brought him into polemical controversy with all the leading agents by whom the business of practical life was carried on at Athens.' (*Ib.* vol. viii. p. 488.) [PLATONISM; SOCRATIC PHILOSOPHY.]

Sophora (Arab. sophera). A genus of *Leguminosæ*, consisting of trees or shrubs found on the seashores of tropical Asia, Africa, America, and Australasia, all having pinnate leaves, and terminal simple racemes or branching panicles of papilionaceous flowers.

S. japonica is a very handsome tree, long ago introduced into the gardens of this country from China; but it is not so frequently grown as, from its ornamental character and hardiness, it deserves to be. It is of quick growth, and forms a large round-headed tree forty feet high or more, in autumn producing at the points of the branches large loosely-branching panicles of small whitish or cream-coloured flowers, which give it a beautiful and conspicuous appearance, though the flowers themselves are small. In China, the flowers are used for dyeing a yellow colour. They are called Wai-fa or Wai-hwa by the Chinese, and are employed to give the fine yellow colour to the silk used for the garments of the mandarins, and also for dyeing blue cloth green. Large quantities of them are thus consumed, the tree being cultivated on this account in the provinces of Fokien, Honan, and Shantung, from whence sacks full of these little flowers are despatched to other parts of the empire. All parts of the tree possess purgative properties, and it is said that even those who merely prune it are affected, as also are turners when employed upon its fine-grained hard wood. The tree is known only in a cultivated state, and its native country is therefore uncertain, though it is most probably indigenous to either China or Japan.

Soporifics (Lat. sopor, *sleep*). Medicines which induce sleep.

Sopra (Ital. *above*). In Music, a term frequently used for description; as *nella parte di sopra*, in the higher or upper part; *di sopra*, above; *contrapunto sopra il soggetto*, counterpoint above the subject, &c.

Soprano (Ital.). The upper or treble part in vocal compositions.

Sorb (Lat. sorbus). The Service-tree, *Pyrus domesticus*.

Sorbic Acid. The acid of the berries of the *Pyrus* (*Sorbus*) *Aucuparia*, or Mountain Ash. It is identical with the *malic acid*.

Sorbonne. A college at Paris for the study of theology; so called from the village of Sorbonne, in Champagne, where its founder, a priest named Robert, was born about the beginning of the thirteenth century. He made a provision for the instruction of sixteen poor clerks in theology, and his college is said to be the first example of what was afterwards the common character of all the English colleges, the institution of a cœnobium for regular clergy. The college of the Sorbonne was adorned with various new edifices and enriched with a library by Cardinal Richelieu, in 1629. (Mosheim, *Eccl. Hist.*) This great college of theology exercised a high influence in ecclesiastical affairs and on the public mind, especially in the sixteenth and seventeenth centuries; insomuch that the sceptical wits of the eighteenth usually employ the name as synonymous with the spirit of bigotry itself. Its proverbial celebrity for acuteness in theological disquisition is attested by the lines of our own Butler:—

> For he a rope of sand could twist
> As firm as learned Sorbonist.

(Hallam, *Literary History*, part iv. ch. ii. § 20, &c.)

Sorcerer (Lat. sortitor, from sors, *a lot*; whence *sorcery*). Properly one who practises sortilege, or divination; but, in the ordinary language of the middle ages, one exercising magical powers, especially by the aid of evil spirits. The *sorcerer* of the middle ages was, generally speaking, a personage of distinction, while the *witch* was degraded and loathsome. Of the species of sorcery which is still practised in the East, especially in Egypt, by means of the magic mirror, the most complete account of it will be found in Lane's *Modern Egypt*. [RATIONALISM; WITCHCRAFT.]

Sordawalite. A variety of Wichtyne, resembling Pit-coal in appearance, found in greyish or bluish-black opaque masses, near Sordawala in Finland, forming thin veins in trap-rock. It is a silicate of alumina, iron, and magnesia, with about three per cent. of phosphoric acid.

Sordini. In Music. [CON SORDINI.]

Soredia (Gr. σωρός, *a heap*). In Botany, heaps of powdery bodies found in lichens lying upon any part of the surface of the thallus.

Sorex (Lat.; Gr. ὕραξ, *a field-mouse*). A Linnæan genus of the order *Bestiæ*, now forming an extensive tribe of Insectivorous Ferines (*Carnassiers*) in the system of Cuvier, and subdivided into different genera. The original generic term is confined to the shrews, or shrew-mice, which are the type of the family (*Soricidæ*), and are characterised by having the two superior middle incisors curved and indented at the base, the two inferior incisors prolonged and procumbent. Behind the upper pair of incisors there are five little conical teeth on each side, and two similar teeth behind the lower pair of incisors: the molars, which are beset with sharp cusps, are four on each side above, and three below. The true shrews are further characterised by lateral, and sometimes anal and femoral, scent glands. The principal genera, now distinct, which would have ranked with the Linnæan *Sorex* are *Myogalea*, *Condylura*, *Tupaia*, *Gymnura*, *Macroscelis*, *Cladobates*, *Solenodon*, *Crossopus*, *Crocidura*. Of these, *Gymnura* belongs rather to the family of hedgehogs, and *Condylura* to that of the moles.

Sorghum (Indian sorghi). A genus of grasses, the species of which are extensively cultivated for food, particularly *S. vulgare*. In Spain, Italy, and other parts of the South of Europe, as well as in Arabia and Asia Minor, this Millet or Guinea Corn occupies a place similar to that which oats and barley hold in the field-culture of the northern parts of Europe. The flour which the round hard seeds yield is very white, and makes good bread when properly manufactured. It is called *durra* in India, and is said to be used chiefly by the lower classes of the population. It is also employed for feeding horses, swine, poultry, &c., where it is extensively grown. It is frequently cultivated in Botanical Gardens in England, where it has been tried also as a general crop, but the climate has been found too cold and damp for ripening its seeds properly. *S. saccharatum* has lately been recommended as a fodder grass.

Sori (Gr. σωρός, *a heap*). The small heaps of reproductive granules found growing upon the fronds of Polypodiaceous ferns.

Sorites (Gr. σωρείτης, from σωρός, *a heap*). In Logic, an abridged form of stating a series of syllogisms, in which the conclusion of each is a premiss of the succeeding one: e. g. A=B, B=C, C=D; therefore A=D. This is a sorites, consisting of two distinct syllogisms, which, drawn out at length, would stand thus: A=B, B=C; therefore A=C; and A=C, C=D; therefore A=D.

Sorosis (Gr. σώρευσις, *a heaping up*). In Botany, the term applied to those fruits which consist of a fleshy mass formed by a consolidation of many flowers, seed-vessels, and their receptacles, as in the Pineapple, the Bread-fruit, &c.

Sorrel, Salt of. Binoxalate of potash.

Sortes Homericæ, Virgilianæ, Sanctorum, &c. A species of sortilege or divination was practised in antiquity by opening at random a favourite author, and applying the first passage which met the eye to the circumstances of the enquirer as an oracular answer: termed by the Greeks στοιχειομαντεία. They chiefly used Homer for this purpose. Thus

Socrates when in prison, hearing the line of Homer repeated,

ἤματί κεν τριτάτῳ Φθίην ἐρίβωλον ἱκοίμην,

interpreted it to foretell his own death within three days, by a play on the word Phthia. Among the Romans, Virgil was chiefly consulted, and many celebrated instances are preserved. Hadrian, when desirous to know on what terms he stood with his patron, the emperor Trajan, consulting the *Æneid*, opened at the verses respecting Numa, 'Nosco crines incanaque menta Regis Romani,' &c.; and thence drew the augury of his future elevation to the empire. Alexander Severus, according to Lampridius, obtained a similar presage from the lines 'Excudant alii spirantia mollius æra,' &c. The anecdote of the ominous passages discovered by Charles I. and Lord Faulkland, when opening Virgil in the public library at Oxford, is well known. (Welwood's *Memoirs*.) In Christian times, the Sortes Sanctorum came in fashion. They were obtained by consulting the Biblical writings in the manner before described; sometimes, also, the enquirer went into a church while service was performing, and drew a prognostic from the first words he heard. In this way, St. Anthony was directed to adopt a life of solitary devotion. These practices became the occasion of much superstition. They are condemned by St. Augustine in his Epistle to Januarius; but are, nevertheless, continually mentioned, with evident credulity and approbation, by early ecclesiastical writers. Gregory of Tours, among other similar stories, has one of the French prince Meroveus, which shows the ceremonious manner in which they were sometimes performed. That prince having fled to the basilica of St. Martin, placed separately on the saint's tomb the Psalms, the Book of Kings, and the Gospels, and, spending three days and nights at the tomb in fasting and devotions, on the fourth day he opened these sacred books; from each of which he drew a discouraging prediction. Elections to the episcopal offices, and other solemn proceedings, seem to have been sometimes decided in the same manner in the dark ages. And after this abuse had ceased, it was long a common practice, on the consecration of a bishop, after the book of the Gospels had been laid on his head, to consider the first verse which offered itself as a prognostic of his behaviour and the fortunes of his episcopacy. The Sortes Sanctorum had been, however, forbidden by the council of Vannes in the fifth century, and that anathema was repeated on many later occasions, in which this method of consulting the Scriptures is classed with other profane and magical modes of divination. There is an essay on Sortes in the *Mém. de l'Acad. des Inscr.* vol. xix. [STICHOMANCY.]

Sortie (Fr.). In Military language, a sudden attack made by the garrison of a besieged place upon the besiegers.

Sortilege (Lat. sors, *lot*; lego, *I collect*). Divination by lots. The different modes in which sortilege has been practised will be found detailed under that word, in a learned article in the *Ency. Metropolitana*. [MAGIC; SORTES; WITCHCRAFT.]

Sospiro (Ital. *a sigh*). In Music, the same as REST.

Sostenuto (Ital. *sustained*). In Music, a term which, affixed to a note, indicates that it is to be held out in an equal and steady manner.

Sothiac Period. In the artificial Chronology of the Egyptians, a period of 1,461 years, based on the observation that the movable year of 365 days, and the fixed year of 365¼ days could not, after starting from the same point, again coincide, until a cycle of 4 x 365, i.e. of 1,460, years had been completed. This period is also termed Canicular, Sothis being the Egyptian name for the dog star. A passage of an ancient chronicle, cited by Syncellus, speaks of a great cosmical period of 36,525 years, made up of twenty-five Sothiac periods. The later chronology was constructed on the same principle. Theon of Alexandria reckons an era of Menophres as beginning in the year 1322 B.C., which corresponds with the first year of the Canicular period, whose termination is mentioned by Censorinus (1322 + 139 = 1461); and therefore it may be inferred that the era of Menophres was a period of 1,461 years, calculated backwards from A.D. 139, in which the first of Thoth (the first month) in the Egyptian movable year, occupied its proper place at the rising of the dogstar. This period is not mentioned by Herodotus, or by any other writer before the Christian era. (Sir G. C. Lewis, *Astronomy of the Ancients*, ch. v. § 9; Grote's *History of Greece*, part ii. appendix to ch. xx.)

Sothic Year. The Egyptian year of 365 days was so called from Sothis, the dog star, at whose heliacal rising it was supposed to commence. [SOTHIAC PERIOD.]

Sotto (Ital. *below*). In Music, a term frequently used for description; as *sotto il soggetto*, below the subject; *nella parte di sotto*, in a lower part.

Sou (Lat. solidus, sc. nummus, *a solid coin*). A French coin, the twentieth part of a franc.

Souari Wood. A valuable Demerara timber, the wood of *Caryocar tomentosum*.

Soujee. A species of Semolina; it is a granular preparation of wheat deprived of bran.

Soul. This word, which is still used in many senses, is more distinctively employed to denote the spiritual, or immaterial, or immortal, portion of human nature; but even in this sense it has not attained, and is perhaps incapable of receiving, a precise philosophical meaning. Like all other words which have been used to convey purely intellectual ideas, the term *soul* has a strictly sensuous origin. As the words which we now use to signify the spirit of God meant originally only the breath of the air or sky, so the word *soul*, as applied to the thinking faculty in man, is a metaphor derived from the heaving and restless *sea*. 'Soul,' says Professor Max

Müller, 'is the Gothic *saivala*, and this is clearly related to another Gothic word, *saivs*, which means the sea. The sea was called *saivs* from a root *si* or *siv*, the Greek σείω, to shake; it meant the tossed-about water in contradistinction to stagnant or running water. The soul being called *saivala*, we see that it was originally conceived by the Teutonic nations as a sea within, heaving up and down with every breath, and reflecting heaven and earth on the mirror of the deep.' (*Lectures on Language*, first series, ix.) To the objection made to this derivation, on the ground that poetry is thus made to do duty for logic, it is sufficient to reply in the words of Locke, that in all languages the names which stand for things not falling under our senses have had their first rise from sensible ideas. This proposition, as put forth by Locke, was in part a conjecture, grounded on an examination of certain words; but the progress of philology has fully established the fact. [LANGUAGE; METAPHOR.] The metaphorical character of this name for the thinking faculty of man, is further shown by the unconscious instinct with which poets resort to the idea embodied in it. (*Quarterly Review*, April 1866, p. 412.)

In this its original meaning, the word denoted simply a present fact, or the impression conveyed to the speaker by certain phenomena which he was contemplating. It had now no reference either to the source of this faculty or life, or to its ultimate duration, whether here or in any other state of existence. The soul was the heaving sea within man, during the whole of that period in which the words *Dyaus*, Ζεύς, Θεός, *Deus*, signified simply the heaven to which men looked up from the earth. The history of language carries us back to a time during which men existed without any consciousness of kinship, marriage, or law, or of their relation to a Being who was their maker. The first formation of the ideas of father, mother, wife, and brethren, the growth of the numerals, of words like duty, right, love, of the idea of a Creator, Ruler, and Father of men, mark severally, in Professor Max Müller's judgment, a stage in the revelations made to mankind.

How soon these words began to convey ideas similar to those which we now attach to them, it is impossible to say. But it is quite certain that the word *soul* assumed gradually the meaning of a living, thinking, or conscious power, and equally certain also that while some held this power to be indestructible, others either denied this conclusion, or rested content without any conclusions on the subject. In other words, the belief in the inherent immortality of the human soul, although affirmed by some to be an innate conviction in the human mind, has not been accepted at all times or in all countries. From the Buddhist theories of Nirvana it may perhaps be rash to draw any inference [UPADANA]; but in the western world the denial of this doctrine has been formalised in philosophical systems, more especially in the later phases of that of Epicurus. A treatise of Philodemus, *On Death*, found among the Herculanean papyri, attests (if any evidence were needed) a condition of thought in which the mind calmly accepted the grave as the limit of its destiny, and 'acquiesced without an effort in the contented consciousness of annihilation.' It has been further remarked that this is no passing allusion to the sleep of death. 'Philodemus coolly discusses all the circumstances of death, and calmly puts aside all the terrors which they involve, by the single consideration that since man, by the enjoyment of life, has attained the chief good, he is not to concern himself with what may afterwards befal. The children, therefore, whom we may leave behind us, are no more to us than they are to those who were born to King Phoroneus.'

In the Aristotelian philosophy, the idea of a future or continued existence after death can scarcely be said to have a place. His system of ethics is simply a part of his great theory of politics, and his morality is confined, therefore, essentially to present conditions. The passing reference made to the subject in the first book of the *Ethics*, shows a singular indifference to a question on which the philosopher was content to balance one conjecture against another. He will not take upon himself to assert, like Philodemus, that the fortunes of the children can in no way affect their ancestors; but he thinks that the impressions conveyed are like those with which we may regard those incidents in a play which are supposed to be enacted behind the scenes, and which do not therefore pass before our eyes. Thus the continued existence of men after death was with Aristotle an open question, for which he did not greatly care to have an answer.

The Platonic philosophy, or the Socratic (if we may suppose that on this subject the disciple faithfully represented the master), introduces us to a wholly different phase of thought. The idea of duty, as based on responsibility, to an unseen but absolutely impartial judge, runs through the great dialogue entitled the *Gorgias*. The belief, if grounded in part on metaphysical arguments, rests chiefly on a profound internal conviction. After death comes the judgment, and as the tree falls so it lies. As the corpse retains the features seen in life, with any marks or scars which may have been made in the body, so the soul retains its spiritual features, with the wounds or scars which may have been caused by unjust actions. The souls, dismissed from the body, are brought before Rhadamanthus the judge, who knows not to whom they belong, and whose impartiality cannot therefore be called into question; and the souls of kings, rulers, and statesmen, are thus submitted to a trial, at the end of which sentence is passed according to the condition in which they are found. Those which are found unscarred go to the islands of the blessed; while all who are wounded and distorted from the effects of tyranny, intemperance, sloth, or lying, are dismissed to the prison-house where they are to receive due punishment.

The souls so dismissed are divided into two classes, the curable and the incurable, for punishment must be either for the reformation of the offender or as a warning to others. For all, therefore, who have not sinned incurably, the punishments of Hades become a purgatorial process, and in this class are placed the souls of private citizens who have never been invested with great power or responsibility. According to the Platonic Socrates, it is impossible for such insignificant persons to commit incurable sins, this terrible privilege being reserved for despots, unjust kings, and iniquitous rulers of whatever kind. Thus, for the vast mass of men, the punishments of the unseen world issue in reformation and final happiness.

The Platonic belief was adopted by Cicero, who sums up in his treatise, *De Senectute*, the metaphysical arguments on which belief in the immortality of the soul has been based. Not only will the soul exist hereafter, but it has existed before the birth of the body. [REMINISCENCE.] It is a portion of the universal Divine Mind, and its power of remembering the past, its foresight, and its achievements in science and art furnish conclusive evidence that the nature which can do all this is immortal. The mind, again, is never at rest, and its motion, as not being caused from without, originates with itself, and can, therefore, have no end, as the soul cannot abandon itself. It is, again, simple and indivisible, and that which is indivisible is also indestructible. His belief in a conscious personal existence after death Cicero expresses rather incidentally than in positive propositions; but his own convictions may be seen in the words in which Cato is represented as expressing his longing to be again with his own son, and with great and good men whom he had never seen on the earth.

But neither in the time of Cicero, nor at any other period of Roman history, can it be said that there was a general belief in the inherent immortality of the soul. So far as Tacitus can be adduced as having a settled belief, he had come to the conclusion that man, as such, was not immortal, but that immortality might be conferred as a special reward on great souls (*Agricola*, 46), and Tacitus represents probably the better aspect of Roman thought.

The arguments urged by Bishop Butler (*Analogy*, part i. ch. i.) agree generally with those which Cicero derived from the Platonic philosophy, while in some points they extend the field of enquiry, and introduce new considerations which may materially affect the question at issue. Of death in itself we know nothing, but only some of its effects, as the dissolution of flesh, skin, and bones; hence the reason of the theory fails to connect death with the destruction of living agents, and thus there is no presumption that any 'animals ever lose their living powers.' The body is, therefore, defined by Butler to be a living power, which makes use of the limbs as instruments; and as only these instruments are subject to the change called death, it follows that the body (as being a living power) never dies. This conclusion only presents in another form the Platonic argument of the indiscerptibility of the human soul; and thus from Butler's position it follows, apparently, that man is one indivisible living power, and therefore that the distinction between body and soul has no foundation in fact. Butler likewise saw that his argument was capable of application to the life or soul of brute animals, and he did not shrink from so applying it. The raising of a difficulty on this account he regards as both invidious and weak, for we know not with what latent powers and capacities they may be endowed, and, secondly, 'the natural immortality of brutes does not in the least imply that they are endued with any latent capacities of a rational or moral nature; and the economy of the universe might require that there should be living creatures without any capacity of this kind.'

But while it has become a habit with many to appeal to the universal consent of mankind as evidence for the inherent immortality of man, both this appeal and the metaphysical arguments on which this belief is maintained are confronted by a system of philosophy, sometimes called materialistic, which sees in human life the expression of forces dependent on certain material combinations, and which, asserting that consciousness is the result of that combination, affirms that, with the dissolution of that combination, the conscious life will also be at an end. Into the vast field of discussion thus opened it is unnecessary to enter in an article which is designed simply to sketch the chief theories or convictions which have been propounded on the subject. It may, however, be remarked that, in the system of Bishop Butler, the soul seems to be identified with the principle of reflection or conscience, which he holds to be supreme in authority, as it ought to be supreme in power, and that here, again, the subject branches off into many complicated enquiries. According to Butler, the conscience is a substantive innate faculty or power, the voice of God speaking within us; according to the 'Association' psychology, that which we call conscience is the result of experience, varying indefinitely with the civilisation in which man may find himself, and with the particular circumstances of his life. (Bain, *The Senses and the Intellect: The Emotions and the Will.*)

And, finally, it may be noted that, while the idea of inherent immortality is generally maintained by Christian theologians, the consent is by no means universal. There are many who share the belief of Archbishop Whately (*Scripture Revelations of a Future State*) that immortality is a gift reserved only for those who shall be found worthy of it; the eternal death spoken of in the New Testament being the final extinction of the sinner, and not his continued existence in a state of endless torment.

Professor Bain gives the following classifi-

cation of views held by different schools of philosophy on the subject of the Soul.

I. Two Substances.
1. Both material: most of the ancients; the early fathers.
2. An immaterial and a material: commencement in Plato and Aristotle; the later fathers; the schoolmen; Descartes; prevalent opinion.

II. One Substance.
1. Mind and matter the same: the cruder forms of materialism; the pantheistic idealism of Fichte.
2. Contrast of mind and matter saved: guarded or qualified materialism, held by many physiologists and metaphysicians; the growing opinion.

For a sketch of the Hindu philosophy on the subject, the reader is referred to the Introduction to Professor Max Müller's *History of Sanskrit Literature*. See also Alger's *Critical History of the Doctrine of a Future Life, with a complete Bibliography of the Subject*, Philadelphia 1864; Bain, 'Historical View of the Theories of the Soul,' *Fortnightly Review*, No. xxv., May 15, 1866.

Soulamea. A genus of the *Simarubaceæ*, peculiar to the Moluccas and the Feejee Islands. *S. amara*, the only species, is a tree with simple alternate obovate leaves, and small green flowers in short axillary spikes. Like the *Quassia* and most others of the family, this plant is excessively bitter in all its parts. The root and bark, bruised and macerated in water, are used in India, Java, the Moluccas, &c., as emetics and tonics, in pleurisy, asthma, cholera, snake-bites, epilepsy, &c.

Sound (Fr. son, Lat. sonitus). The sensation produced by the vibrations of the air or other medium with which the organ of hearing is in contact. The doctrine of sound is usually treated under the head *acoustics*; a branch of physics which has for its object the determination of the laws by which the peculiar motions which give rise to the sensation of sound are produced in bodies and conveyed to our ears, and the manner in which they act on those organs; in other words, to explain the origin, propagation, and perception of sound.

Although, strictly speaking, sound is only a sensation excited in the auditory organ, yet in treating of the subject it is usual to transfer the name from the sensation to the motion which gives rise to it. We shall therefore speak of sound as if it proceeded from the *sounding* body; and speak of a body as sounding when its particles are in that state of vibration which is requisite for making an impression on the ear, either immediately or through the medium of some other elastic substance.

Transmission of Sound.—In order that a body may produce sound, it is necessary that its particles be in a state of rapid vibration; and in order that these vibrations may be communicated to the auditory organ, it is necessary that air or some elastic medium be interposed between the vibrating body and the ear. Hawksbee having suspended a bell under the receiver of an air-pump, found the sound become feebler in proportion as the air was removed, and again become stronger as the air was readmitted; and also that when the bell was suspended in a vessel full of air, and placed under the receiver, no sound was transmitted when the air between the vessel and the receiver was exhausted. This experiment has been repeated by Biot, with a more perfect apparatus, and with every attention to the circumstances by which it is influenced; and it was found that when the exhaustion was complete no sound was perceptible, even when the ear was brought close to the receiver. Hence it appears that sound cannot be communicated through a perfectly void space. But although air is the medium through which sound is usually communicated, this happens only because it is the medium with which the ear is usually in contact; and many other media are found by experiment to perform the office even more perfectly. Franklin having plunged his head under water, caused a person to strike two stones together beneath the surface, and at more than half a mile distance heard the blows distinctly. Colladon, in 1827, by plunging into the water a spoon-shaped trumpet closed at the lower end, but having the upper—to which the ear was applied—open to the air, was by this means enabled to hear the sound of a bell struck under water at the distance of 12,000 mètres, or about nine miles. The experiment was made across the whole breadth of the lake of Geneva, from Rolle to Thonon. The conducting power of wood along the fibres is very remarkable. Let a person bring his ear close to the end of a fir deal, however long, and he will distinctly hear the slightest scratch made with the point of a pin at the other end, although the sound may be so feeble as to be inaudible to the person who makes it. Miners at work in one shaft often hear the sound of the pickaxe in another through the solid rock; and in general all solids tolerably compact are good conductors of sound.

Sounds are propagated to great distances and with remarkable distinctness over a surface of water, or ice, or frozen snow. In the account of Parry's third polar expedition, it is stated that two persons could hold a conversation across the harbour of Port Bowen, a distance of 6,696 feet, or about a mile and a quarter. Instances are also recorded of sounds propagated to almost incredible distances over land. Derham relates the following: Guns fired at Carlscrona were heard across the southern extremity of Sweden, as far as Denmark, a distance of 120 miles. Dr. Hearn, a Swedish physician, relates that he heard guns fired at Stockholm at the distance of 30 Swedish or 180 English miles. The cannonade of a sea-fight between the English and Dutch, in 1672, was heard across England as far as

Shrewsbury, and even in Wales, a distance of upwards of 200 miles from the scene of action. The firing at Waterloo, it is said, was heard at Dover; and the report of a volcano is said to have been heard 300 miles off.

The diminution of the intensity of sound in rarefied air is rendered manifest not only by experiments with the air-pump, but also by the phenomena observed at great altitudes in the atmosphere. Saussure relates, that at the summit of Mont Blanc the report of a pistol was not louder than that of a small cracker in the plain below; and Gay-Lussac, having ascended in a balloon to an altitude of nearly 23,000 feet, observed the intensity of the sound of his voice to be greatly enfeebled.

Velocity of Sound in Air.—It is a familiar observation that sounds are not propagated through the air instantaneously, but occupy a sensible portion of time in passing from one station to another, greater in proportion as the stations are more remote. The blow of a hammer on an anvil is not heard by an observer at some distance, until a sensible time has elapsed after the hammer has been seen to descend; and the flash of a gun fired a mile off is seen several seconds before the report is heard. But all sounds, whatever be their loudness or pitch, are propagated with the same velocity through the same medium. In listening to the music of a concert, the sounds follow each other in the same order and at the same intervals; and the same measure and harmony are perceived, at whatever distance the hearer may be from the orchestra. Biot caused several airs to be played on a flute at the end of a pipe 3,120 feet long, which were distinctly heard at the other end without the slightest derangement in the order or intervals of sequence of the notes. This could not have been the case if there had been the smallest difference in the velocity of their propagation.

Numerous experiments have been made for the purpose of determining the actual velocity of sound through the atmosphere. The usual mode of making the experiment is to observe the interval between the flash and the report of a cannon fired at a known distance. In this manner the Florentine academicians, in 1660, found the velocity to be 1,148 English feet per second. These experiments were repeated in France in 1698, by Cassini, Huygens, Picard, and Roemer, who found 1,172 feet; and Flamsteed and Halley at the Royal Observatory of Greenwich, from experiments made at the distance of three miles, found the velocity to be 1,142 feet per second. This result was confirmed by Derham (*Phil. Trans.* 1708), who found the same velocity by a mean of observations made at more remote distances. In 1737, the Academy of Sciences of Paris directed further experiments to be made by Cassini de Thury, Maraldi, and Lacaille; and on this occasion the experiments were for the first time made so as to eliminate the effect of the wind by reciprocal observations, i.e. by firing cannon at both ends of the line, either simultaneously or at short intervals. They also appear to have been the first who observed and recorded the temperature of the air at the time of the experiment—a very essential element, as will presently be seen. The result at which they arrived gave the velocity equal to 1,106 English feet per second, at a temperature between 4° and 6° of Réaumur, or between 41° and 44½° of Fahrenheit. When the proper reduction is made for temperature, this agrees very nearly with the best modern observations.

Since the beginning of the present century, the velocity of sound has been measured by numerous observers with great care. The following table contains a summary of these and other results:—

Date of Observation	Observer	Distance of Stations in Feet	Velocity per Second in English Feet at the Temperature of Freezing Water
1809	Benzenberg . .	29764	1095
1821	Goldingham .	29547 13932	1086·7
1822	Myrbach . . .	32615	1092·1
1822	Arago, Mathieu, &c.	61064	1086·1
1823	Moll and Vanbeck .	57839	1089·42
1823	Dr. Gregory .	from 2700 to 13460	1088·05
		Mean of the whole	1089·2

These results agree remarkably well with each other, the greatest deviation from the mean being less than four feet, and the mean of the whole being almost identical with the determination of Moll and Vanbeck. 'We may, therefore,' says Sir John Herschel, 'adopt 1,090 feet without hesitation (as a whole number), as no doubt within a yard of the truth, and probably within a foot.' This is the velocity with which sound travels in dry air, at the temperature of freezing water. But the velocity increases with the temperature (as will be shown presently) at the rate of 1·14 foot, very nearly, for each degree of Fahrenheit's scale. Hence at the average temperature, say 60°, the velocity of sound is about 1,120 *feet per second.*

Theoretical Determination of the Velocity of Sound.—The investigation of the velocity of sound through the atmosphere (or any gaseous medium) is based upon this fundamental proposition of dynamics, viz. that the velocity of the pulses in an elastic medium is as the square root of the elasticity divided by the density of the medium. Let v = the velocity, e = the elasticity, d = the density; and the proposition gives $v = \sqrt{(e \div d)}$. Make g = the measure of gravity (386·29 inches per second), w = weight of the unit of volume of air, h = height of the homogeneous atmosphere (i.e. of a column of air of the same density throughout, and whose weight exercises on the base a pressure = e); we have then $e = hwd$, $= w \div g$; and the above equation becomes $v = \sqrt{(gh)}$. But this is the velocity which a heavy body acquires by falling in vacuo from a height $= \frac{1}{2}h$; therefore, the velocity with which sound is propagated through the air is the same as

that which a heavy body would acquire by falling through half the height of the homogeneous atmosphere. This proposition was given by Newton in the *Principia* (lib. ii. prop. 47), but from a theory wholly inapplicable. The correct demonstration was given by Lagrange.

In order to convert this formula into numbers, it is necessary to determine h. Let b = the standard height of mercury in the barometer, and m = the ratio of the density of mercury to the density of atmospheric air under the same pressure; then $h=mb$, and the velocity becomes $v=\surd(gmb)$. At the temperature of freezing water (32° Fahr.), and under a barometric pressure of 29·927 inches, the value of m is found by experiment to be 10.466. But we have also $g=386{\cdot}29$ inches; whence at that temperature $v=10{,}998$ inches, or 916 feet.

Since the velocity, as above stated, is proportional to the square root of the elasticity divided by the density, an alteration in the height of the barometer, while the temperature remains the same, will produce no change in the velocity; for an increase of pressure, and consequently of elasticity, is accompanied by a proportional increase of density. An increase of temperature, however, by increasing the elasticity without changing the density, is accompanied by an augmentation of velocity. The correction for a difference of temperature is found as follows: Let t denote the number of degrees of temperature on Fahrenheit's scale above 32°, and a a constant coefficient; then the elasticity at the freezing temperature being e, the elasticity at the temperature t will be $e(1+at)$. But the value of a is found by experiment $=\cdot00208$; therefore the elasticity is $e(1+\cdot00208\,t)$; and the formula for the velocity becomes $v=\sqrt{gmb\,(1+\cdot00208\,t)}$; or introducing the above value of $g\,m\,b$, $v=916\,(1+\cdot00104\,t)$.

The velocity of 916 feet at the freezing temperature, thus deduced from theory, falls short of the experimental velocity (which has been shown above to be 1,089 feet) by 173 feet, or about a sixth part of the whole quantity. This discrepancy was remarked by Newton, who attempted to account for it by supposing the spherical molecules of air to be perfectly elastic solids, through which sound is propagated instantaneously; but the true solution of the difficulty was reserved for Laplace. The explanation given by Laplace is, that the compression of the air which takes place in the vibration disengages a portion of latent heat, which thus becomes sensible, and modifies the law of the elasticity, thus accelerating the velocity. On submitting this to calculation, he found that the formula for the velocity of sound must be multiplied by a certain factor, viz. the square root of the quotient which is found by dividing the number which expresses the specific heat of the air (or other gas) under a constant pressure by that which expresses its specific heat under a constant volume. Let k = this factor; then Laplace's formula for the velocity of sound is

$$v=\sqrt{gmb\,(1+\cdot00208\,t)\,k}.$$

The value of k for atmospheric air, as determined by Dulong, is 1·421; hence $\surd k=1{\cdot}192$, and the formula in numbers is

$$v=916\times1{\cdot}192\,(1+\cdot00104\,t)=1092+1{\cdot}14\,t,$$

which is almost identical with the experimental determination.

Velocity of Sounds through Liquids and Solids.—The following general formula for the velocity with which sound is propagated through any elastic compressible body, whether liquid or solid, was found by Laplace: Let b denote (as before) the standard height of the barometer, D the density of mercury at the freezing temperature, d the density of the medium, and c the *compressibility* of the medium, i.e. the diminution of bulk caused by an additional pressure equal to one atmosphere; then the formula is

$$v=\sqrt{\frac{gb\,D}{c\,d}};$$

or (since $g=386{\cdot}29$ inches, $b=29{\cdot}927$ inches, $D=13{\cdot}568$), $v=396{\cdot}04\ \surd(1+cd)$ inches, or $33\ \surd(1\div cd)$ feet per second. Applying this to the case of water, we have $c=\cdot000049589$ (Herschel, *Ency. Metrop.*), and $d=1$; whence $v=4{,}687$ feet per second. This result agrees very nearly with the velocity determined by Colladon and Sturm by direct experiment on the propagation of sound through the lake of Geneva, the velocity actually observed by them being 1,435 mètres, or 4,708 English feet, a second, which differs from the theoretical velocity only by 21 feet—a space described by the aqueous pulse in the 200th part of a second.

By the above formula the velocity of sound through any medium of which the compressibility is known is readily computed. According to Chladni, the velocities of sounds in different solids, that of air being taken as unity, are as follow: Tin = 7½, silver = 9, copper = 12, iron = 17, glass = 17, baked clay = 10–12, woods of different kinds = 11–17. But the velocity of propagation through cast-iron tubes was determined experimentally by Biot, and found to be only about 10½ times its velocity in air. (Herschel's *Treatise on Sound*; Chladni, *Traité d'Acoustique*; Biot, *Traité de Physique*.)

It has already been stated that sound is produced by the vibrations of the molecules of any substance communicated to the atmosphere or other elastic medium, and conveyed by it to the ear. The physical theory of sound, therefore, is resolved into two parts: 1st, the state or condition of the vibrating body; and 2nd, the mode in which this mechanical action is propagated through the medium to the organ of sense.

State of Sonorous Body.—In order that a body may emit a musical sound, its particles must be put into a state of rapid and regular vibration. If the frequency of the vibrations is under a certain limit, no sound will be pro-

duced; above that limiting velocity of vibration, sound is produced; and experience shows that the pitch of the sound becomes more and more acute as the vibrations are more rapid, until a second limit of velocity is attained, beyond which the human ear is affected with no sensation of sound. To prove this experimentally, let a strip of tempered steel have one of its ends firmly fixed in a vice, and let the other end be drawn aside from the position of rest. As soon as the force by which the strip is bent is removed, the steel commences a series of vibrations, which become smaller and smaller until the position of rest is again attained. But the vibrations are all performed in equal times, and if sufficient length is given to the strip, they take place so slowly as to admit of being accurately counted. On shortening the strip, they become more rapid; and at a certain length a low sound is emitted. If the strip be still further shortened, a fiddle-bow drawn over its upper edge will be necessary to throw it into vibration, and a higher note will now be heard. By continuing to reduce the length of the strip, the pitch of the note will correspondingly rise; for the excursion of the steel to and fro is augmented in rapidity, and the *pitch* of a note depends on the rate of vibration. It might perhaps be possible so far to shorten the strip, and still to throw it into vibration, that its last shrill note shall be followed by no audible sound.

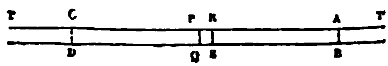
Long before the vibrations of the strip attain that degree of rapidity which is necessary for the production of sound, it becomes impossible to count them directly. But it is demonstrable that when a strip of metal of equal thickness throughout is made to vibrate in the manner now supposed, the time of a vibration is directly proportional to the square of the length of the strip, and consequently the number of vibrations in a given time is inversely as this square; so that if the number in a second corresponding to any length of the strip has been counted, the number corresponding to any other given length can be readily computed. In this manner it has been found that a metallic strip or plate begins to sound when the number of complete vibrations in a second is 16; and at this velocity of vibration, the sound which it gives is of the same pitch as that of an organ pipe 32 feet in length, open at both ends.

This appears to be the minimum velocity of vibration capable of producing sound. The other limit, or maximum velocity at which sound ceases to be appreciable, has also been determined. Until recently it has been usual to fix it at 8,200 vibrations in a second; but Savart has discovered that by increasing the amplitude of the vibrations, acute sounds may be distinguished at a velocity of 24,000 whole vibrations in a second; and more recently Despretz has fixed the upper limit of audible sounds at 36,800 whole vibrations per second. The number of vibrations producing a sound of any given pitch can be determined with great ease and exactness in various ways. Savart employed for this purpose a cog wheel which was made to revolve, and in doing so the teeth were caused to strike a piece of card. A musical sound of any pitch could thus be produced by regulating the velocity of the wheel. The number of revolutions being indicated by machinery, the number of vibrations made by the card could be at once found by multiplying the revolutions of the wheel by the number of teeth it contained. Still more perfectly may the rate of vibration be determined by means of an ingenious instrument, invented by Cagniard Latour, called the *syren*. [SYREN.]

Some of the most acute sounds, or highest tones which the ear can distinguish, are given by the wings of insects; and they correspond to the astonishing rapidity of 12,000 or 15,000 vibrations in a second. When we reflect how extremely probable it is that the tympanum of the ear vibrates in unison with the sounds that affect it, we cannot fail to be struck with the wonderfully delicate organisation of a substance which possesses the power of adapting itself to all velocities of vibration, from 16 times in a second up to 30,000, or even higher. The limits, however, at which very acute sounds cease to be audible appear to vary considerably in different individuals, some being altogether insensible to sounds which painfully affect others. For example, the piercing chirp of the grasshopper is quite unheard by some persons. (See a very interesting paper on sounds inaudible to certain ears by Dr. Wollaston in the *Phil. Trans.* for 1820.)

Propagation of Sound.—In order to convey an idea of the manner in which the vibratory motions of a sonorous body are communicated to the atmosphere or other elastic medium, let us conceive a tube, T T′, of an indefinite length,

Fig. 1.

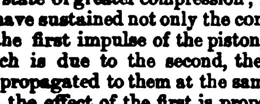


and open at both ends, to be filled with air of a uniform temperature and density throughout. Let us also suppose a piston, P Q, which closely fits the tube, and is movable within it along the direction of the axis, to be propelled suddenly from the position P Q to R S; and to simplify the consideration, let the distance P R be supposed one foot, and the time in which the piston moves from P Q to R S to be one second. Now, assuming the air within the tube to have been in a state of rest before the piston began to move, let us consider what will be its state at the instant when the piston arrives at R S. If the air in the tube were acted upon as a perfectly hard body, any motion communicated to the particles at one extremity would be instantaneously conveyed to the other; and when the piston arrived at R S a quantity of air, equal to that which was contained between P Q and R S, would be expelled at T′, and all the particles within the tube would come to rest at the same time with the piston. But in

consequence of the compressibility of the air the motion is not communicated to the distant particles instantaneously, but only after a sensible interval of time; and we may conceive the tube to be so long that when the piston has arrived at R S no air has yet been propelled from the tube at T'. In fact, the disturbance or compression of the particles, which takes place at the instant the piston begins to move, is propagated along the tube with a certain determinate velocity, depending on the elasticity of the air, and when the piston reaches R S will only have reached to a certain determinate distance. Let A B be the section of the tube which the first compression has reached at the instant the piston comes to R S; then, at the instant of time on which we have to fix our attention, the column of air between R S and A B will be in a state of compression, and betwen A B and the end of the tube at T' it will still remain in its natural state. The column of air between R S and A B, which is thus modified by the stroke of the piston, is called a *condensed wave*.

On attending to the state of the molecules in the column R A, it will readily be seen that they are not subjected to the same degree of compression through its whole length. Conceive the wave to be divided into a very great number of thin layers by sections parallel to R S or A B, and that the piston, in passing from the position P Q to R S, has produced the effect, not instantaneously, but by a great number of successive small impulses. At the instant the piston comes to R S the disturbance has by hypothesis been propagated only to A B, and consequently the particles in the infinitely thin layer next to A B have suffered only the slightest degree of compression, or that caused by the first impulse of the piston. In the second layer next to A B the molecules of air are in a state of greater compression; inasmuch as they have sustained not only the compression due to the first impulse of the piston, but also that which is due to the second, the effect of which is propagated to them at the same instant at which the effect of the first is propagated to A B. In like manner, the compression in the third layer preceding A B is greater than in the second; and so on to the middle of the wave. If we now attend to the state of the molecules at the other extremity R S of the wave, a similar effect will be manifest. The instant after the piston stops, the layer next to

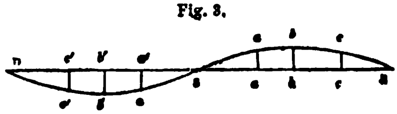
Fig. 2.



R S has communicated all its velocity to the one preceding it, and remains at rest; or, at the moment of the arrival of the piston at R S, sustains only the compression due to the last impulse. The next layer in succession sustains the compression due to two impulses of the piston—the last, and last but one. By following out this mode of reasoning it will readily appear that the particles in the state of greatest compression are those towards the middle of the wave; and that if upon S B, as an axis (fig. 2), we raise a great number of perpendiculars, *a a*, *b b*, *c c*, &c., each proportional to the compression at the corresponding point of the column, the curve drawn through the summits of these perpendiculars will represent the law of compression, and hence is of the form represented in the annexed diagram, the parts on each side of the middle ordinate *b b* being perfectly symmetrical.

If we now attend to the motions developed on the other side of the piston, it will be easily seen that similar phenomena must take place; but in a reverse order, inasmuch as the air within the tube on that side must be rarefied instead of being compressed by the motion of the piston from P Q to R S. Let C D (fig. 1) be a section of the tube, so that the column C R is equal to R A; then, as the velocity of propagation depends only on the nature of the medium, it is obvious that at the instant in which the piston arrives at R S the disturbance of the molecules will have extended only to C D. The whole column between C D and R S will be rarefied by the withdrawal of the piston of air between P Q and R S; but the rarefaction will be greatest at the middle of the column, for the

Fig. 3.



very same reasons which render the condensation greatest at the middle of the column between R S and A B. Hence the column of air between R S and C D is called a *rarefied wave*.

If, now, as in fig. 3, we represent the rarefaction by *negative* ordinates, *a' a'*, *b' b'*, *c' c'*, and the condensation, as before, by the *positive* ordinates *a a*, *b b*, *c c*, the state of the column of air between A B and C D (fig. 1)—and this is all which is modified by the passage of the piston from P Q to R S—will be represented by the double curve D *b'* S *b* B (fig. 3), the small part between P Q and R S being neglected as insensible. The first part of this curve, from D to S, constitutes a rarefied wave; and the second part, from S to B, a condensed wave. Now, as both the rarefied and condensed waves have been produced simultaneously by one motion of the piston, the whole curve from D to B constitutes a single wave or *undulation*. *The length of a wave* is, therefore, the distance between the points D and B, or the distance between the centre of one condensation or rarefaction to the centre of the next.

As every thin stratum of air in the tube, by reason of its elasticity, communicates to the stratum before it the impulse which it has received from the one behind it, all the particles will successively be affected in the same manner; and at the end of a second interval,

equal to that in which the piston has passed from P to Q, the motion will be communicated over another space equal to R A, or the wave will have moved forward its whole length, retaining always the same form; and, supposing the piston to have in this second interval remained at rest at R S, all the particles in the space R A will have returned to their original state of quiescence.

If, instead of supposing the piston to remain at rest at R S, we suppose it to be drawn back, in the second interval of time, to its original position at P Q, then all the phenomena now described will be repeated in the reverse order; i.e. the compressed wave will be to the left of the piston, and the rarefied wave to the right; and the state of the particles within the tube, with respect to their compression, as modified by the advance and subsequent retreat of the piston (a complete *vibration*), will be represented as under (fig. 4).

Fig. 4.

We have now only to suppose this forward and backward motion of the piston to be performed with the same rapidity as the vibrations of an elastic plate or stretched cord, and the phenomena now described will give an idea of the mode in which sound is transmitted through the atmosphere.

From this illustration (imperfect as it is) of the nature of the motions communicated to the air by the vibrating body, it is easy to see that the particles of air in the tube do not change their places inter se, but acquire a vibratory motion, backwards and forwards, along the length of the tube. It is also obvious that the vibrations of the air through which sound is transmitted must be precisely equal in number to those of the sounding body; and as soon as the vibrations cease, those of the air cease likewise. But so long as the body vibrates, or the reciprocal motion of the piston is continued with the same velocity, a continued musical sound will be heard; and this will be precisely the same at whatever part of the tube the ear is situated, all the waves being perfectly similar.

If the production and propagation of a sonorous pulse through a tube has been made clear, it will not be difficult to understand the transmission of sound through an unbounded space of air. Air being equally elastic in all directions, the origin of a sound is a centre from which sonorous waves are propagated in *every* direction. A sounding body thus produces a spherical wave, which rapidly recedes from its source, and, expanding as it does so, its intensity must diminish as the square of its distance from the source increases. As the motion of the sounding body continues, the alternate condensations and rarefactions of the air give rise to a series of concentric spherical waves; a notion of which in section can be derived from rapidly dropping water on one spot on the surface of a quiet lake: the vibrations are here, however, transversal.

Sounds differ from one another in three respects—pitch, intensity, and quality. The *pitch*, or height of the note, depends on the length of the wave, or (which comes to the same thing) on the number of vibrations in a given time. The length of a sonorous wave can therefore be found by dividing the space passed over by sound in one second, in other words the velocity of sound, by the number of vibrations executed in that time; the quotient is the length of the wave produced by that particular note. The gravest tone which the ear can distinguish corresponds to a wave of about seventy feet in length, and the most acute to one of about half an inch. The *intensity* or loudness does not depend on the length of the wave, but on the degree of compression which the air receives; i.e. on the violence of the impulses, or the length of the stroke of the piston in the above illustration. This more forcible stroke causes the particles of air to vibrate through wider spaces; increasing, that is, the height of the ordinates in fig. 3. Hence the intensity of a sound depends on the *amplitude* of the vibration, and is proportional to the square of that amplitude. The *quality* of sound (the *timbre* of the French authors) is less readily explained. It depends in part on the greater or less abruptness of the impulses, and gives rise to the variety in the sounds emitted from different musical instruments. A fuller explanation will be found under the word TIMBRE.

Like light, sonorous waves can be reflected and brought to a focus by a concave mirror; striking on a smooth plane surface, they are reflected to the source, and when this is sufficiently distant the reflected sound gives rise to an *echo*. Sound can also be refracted, and the waves converged to a focus by a suitable lens.

SOUND. In Geography, a strait or inlet of the sea. The name is specially applied to the strait which connects the German Sea with the Baltic.

Sounding. The process of discovering the depth of water beneath a given point, ordinarily on a ship or boat. It may be resorted to merely for a permanent survey, or more commonly for the guidance of the navigator in passing through dangerous seas. The instrument used is a long lead at the end of a light line. In comparatively shallow water the *hand-lead line* is used; its length not exceeding thirty fathoms. In greater depths, resort is had to the *deep-sea line*, which is of unlimited length. The depth is marked by knots on the lines. It is of course important that the plunge of the lead should be as vertical as possible.

Sounding Lead. [LEAD FOR SOUNDING.]

South (A.-Sax. suth, Ger. süd). One of the four cardinal points of the compass; the direction in which the sun always appears at noon to the inhabitants of the northern hemisphere without the tropic.

South Sea Company. In 1711, the proprietors of certain government debts were formed into a joint-stock company, which, in consideration of certain exclusive privileges of trading to the South Seas, offered the government easier terms for the advance or negotiation of loans than could be obtained from the general public. The charter dated from the first of August. The financial expedient of a system by which public debts should be farmed by a company was frequent and to some extent advantageous, and the doctrine that parliament could or should give monopolies of foreign trade was generally accepted. In the present case, it seems that the scheme was intended to rival that of the bank of England. It was favoured by Harley and the Tories, and it was stipulated in the charter that no person should be at once a director of this company and that of the Bank or the East India Company. It was provided that even if the public debt were redeemed, the monopoly of trade should be perpetual. At the time when the company was formed, its stock stood at 77½ per cent., East India being 124½, Bank 111½; and for some time the price of the stock did not rise materially; nor did the company regularly enter on its trading schemes till 1717, when its first annual ship was sent to Vera Cruz.

The origin of the famous bubble of 1720 was the proposal on the part of the directors of the South Sea Company to negotiate all the public debts, at certain rates, and the rivalry which this excited on the part of the bank of England. So keen was this rivalry, that the general public anticipated enormous advantages from the plan, and the stock rose rapidly. It was 126 in Dec. 1719, and reached 319 in the spring of 1720. By the 1st of May it was 400; by June 2, 890. On June 3, it ranged between 640 and 770. On the 6th it was 820, on the 14th 710. By Midsummer it reached 1,000, and other stocks, as that of the East India Company and the bank of England, were similarly exalted. It was said that the advanced prices of all three stocks were computed at 500 millions sterling, and that this sum represented five times all the cash in Europe, and double the value of the lands and houses in England. In order to keep up the price of the security, the South Sea Company, now high in favour with the government, procured a scire facias against the numerous schemes then afloat.

The infatuation, however, was universal. The newspapers were crowded with advertisements of new companies, subscriptions were eagerly paid, and the projectors decamped with the spoils. 'So great was the wild confusion in 'Change Alley, that the same project or bubble was known to be sold at the same instant of time ten per cent. higher at one end of the alley than it was at the other.' One projector actually advertised for a subscription of two millions on a certain promising and profitable design, which would hereafter be promulgated. Pieces of playing-card, called *globe permits*, because they had the impression of a globe in wax, which purported to be a security that the possessor would hereafter be entitled to subscribe into a new sail-cloth manufactory, were sold for sixty and seventy guineas. A list of bubbles is given in Macpherson's *History of Commerce*, some of them being hardly less absurd than the satirical suggestion of a company, with a subscription of two millions, for the invention of melting down sawdust and chips, and casting them into clean deal boards without cracks or knots.

The South Sea Company discovered its error in suing out a suit of scire facias against some of these bubbles, and foresaw that, unless they adopted some expedient, their own ruin was involved in that of their competitors. To defer it, they issued a notice on August 30 that the half-year's dividend should be at the rate of 60 per cent. and that for the next twelve years it should be 50. But these magnificent promises were discredited. The stock sank from 810 on the 1st of September to 410 on the 20th, and to 130 by the last day of the month.

The fraudulent directors of the company, among whom was Mr. Aislabie, the chancellor of the exchequer, were prosecuted and fined, and some small assistance was given out of their estates to a few persons who had been swindled by these officials. But of course a vast mass of misery and ruin remained pitied but unassisted, and long afterwards the most prominent among the great speculations of the year 1720 was known as *the Bubble*.

For thirty years afterwards the South Sea Company continued their trade, though with very imperfect success, and up to almost the present time the capital subscribed to government, which was the plea of their exclusive privileges, was treated as a separate debt, under the name of South Sea Stock.

Southcottians. In Religious History, the followers of Joanna Southcott, who was born at Gittisham, in Devonshire, in 1750, and seems to have first persuaded herself of her miraculous calling in 1792. From that time she traversed the west of England, preaching and prophesying, with a select body of followers, and gradually collected about her a considerable number of disciples. She came to London about 1803, when she announced a meeting for the purpose of satisfying the world of the reality of her mission. Several such meetings took place, the last in 1804; and many persons, including several clergymen, attested their belief in her pretensions. At last, in 1814, she announced her supernatural pregnancy; and this strange announcement took great hold on the public imagination, Dr. Reeve and other medical men having declared their belief that she was actually pregnant in her sixty-fifth year. Her death, in December of that year, did not undeceive her disciples: even when her body was opened, and no trace discovered to verify her assertions, many of them continued to proclaim their

belief in her future reappearance. Her sect continued to exist for many years, nor is it yet altogether extinct.

Southernwood (said to be corrupted from Suddenwood, which name arose from the rapidity with which slips of this plant become suffruticose). A fragrant cottage-garden shrub, the *Artemisia Abrotanum* of botanists.

Sovereign (Fr. souverain; Ital. sovrano; Lat. supernus, *on high*). In Politics, a person, or body of persons, in whom the legislative authority rests in every state. A sovereign state is one in which the jurisdiction of that person or body, within the limits of the state, is absolute and uncontrolled by any foreign authority. The states which composed the German empire were termed, in the language of politics, *mi-souveraines*, because their sovereignty was qualified by their subordination, in some respects, to the imperial authority. The same term should seem applicable to the several states in the American Union, which are commonly, but improperly, termed sovereign; as, on some definite subjects, the power of their legislative bodies is subordinate to that of congress, or the sovereign body in the federal government. [STATE RIGHTS.]

SOVEREIGN. An English coin of the value of twenty shillings, the standard weight of which is 5 pennyweights and 3·27 grains, or 123·374 troy grains. [NUMISMATICS.]

Sow. A movable shed, intended to protect the miners or party using the battering ram in a siege of the middle ages. It corresponds to the ancient *vinea*.

Sow. [SUS.]

Sowans or **Sowins.** The husk and some adhering starch separated from oats in the manufacture of oatmeal are sold, says Dr. Christison, under the inconsistent name of *seeds*; these, if infused in hot water and allowed to become sourish, yield, on expression, a mucilaginous liquid, which, on being sufficiently concentrated, forms a firm jelly, known by the name of Sowins. A similar preparation from groats or oatmeal is called *flummery*.

Sowbread. The common name for *Cyclamen europæum*.

Sowing. In Agriculture and Horticulture, the process of depositing seed in the soil for the purpose of producing plants. The operation of sowing is generally performed in spring, in order that the plants may have the advantage of the coming summer. The seed is either scattered abroad, or deposited in rows or drills; on a small scale by the hand, and on a large scale by a sowing machine. Some seeds which are of large size are planted singly. The covering of seeds is greater or less, according to their size and the texture of the soil. Where the soil is somewhat firm, and the seed is pressed into it by a roller, or by other means, and where the climate is moist, very little covering is necessary; but where the soil is loose, and the climate dry and warm, the covering should be twice or thrice the thickness of the seeds. As the seeds of plants are the natural food of birds, insects, and vermin, in a state of culture artificial protection is required from their natural enemies.

Sowing Machine. A machine for depositing seeds in the soil, either by scattering broadcast, or by dibbling individually, or by placing them in rows, at a greater or less distance asunder. Machines for sowing seeds in rows are termed *drills*. [DRILLS.]

Soy (Japanese sooja). A sauce originally prepared in the East, and said to be produced from the beans of *Soja hispida*.

Soymida (its name among the Telingas). The Rohuna of Hindustan, *S. febrifuga*, is the sole representative of a genus of *Cedrelaceæ*, peculiar to the East Indies. On the Coromandel coast it is known as the Redwood-tree. It is, in fact, a kind of mahogany, and its dull red hard heavy wood is very durable. The bark is a useful tonic in intermittent fevers; but in too large doses it is apt to derange the nervous system, occasioning vertigo and subsequent stupor. It has also been employed successfully in India in bad cases of gangrene, and in Great Britain in typhus fever, and as an astringent. It is a tall tree, with a very bitter astringent bark.

Spa. A place celebrated for its mineral waters, about seven leagues from Aix-la-Chapelle. The term is now generally applied to places at which there are mineral springs.

Space (Lat. spatium). This word signifies generally extension in all directions. Sometimes it has a less general signification; for we speak of distances and areas as spaces of one and two dimensions.

SPACE. In Geometry. Space is not the mere notion of room in which a material object does or may exist, but it is the room in which an object, actual or imaginary, determinate necessarily as to its *form* and possibly as to its *magnitude* and its *position*, does exist. *Form* is the position of all the points of an object as determined by the angular distances between each of them and all the others, and necessitates that a point in or without the object be given. *Magnitude* is determined by the linear distances between any one point in an object, and all other points in it, and requires as given a certain fixed length—a unit of measurement. The form of an object being determined, if the distance between any two points in it be given, the magnitude is determined. *Position* is determined by the linear and angular distances of all the points in an object from at least two points in another object whose position is given. If the form and magnitude of the first object be already determined, the linear distances between any two points in it and any two points in the second object will determine the position of the former, provided that these four points be not all in the same plane. The most generally convenient and common method of determining the form and position of an object is to assume three infinite planes, supposed to be fixed in physical space, at right angles to

each other. These planes will intersect in three lines perpendicular to each other, called the *axes of co-ordinates*. These have a point of common intersection, called *the origin of co-ordinates*, or more commonly *the origin*. Three planes parallel to these planes passing through any point in the object, whose form, &c., are to be determined, will cut the axes in three points, and thus by the portions of the axes cut off between these points and the origin determine the position of that point of the object. These portions of the axes are called the ordinates of that point. If the complete set of the ordinates of all the points of the object be given, its form and position are determined. In certain cases, these can be all given in one or two algebraical formulas which are called the equations to the object. Whenever a unit of distance is given, explicitly or implicitly, in connection with the ordinates of the various points of an object, then not only its form and position, but also its magnitude, is determined. The angular measurement between any two points of an object whose form and position are required is implicitly involved in the system of rectangular co-ordinates, and may be found explicitly from the relations of the sets of ordinates by which these points are determined. It is the assumed perpendicularity of the co-ordinate planes which gives the necessary data for this. These planes need not be assumed to be perpendicular to each other, but then the angles which they make with one another must be known. All material objects possess length, breadth, and thickness, or extension in three dimensions; and if purely geometrical objects, all solids, curved surfaces, and curves of double curvature, must be determined similarly according to their extension in three directions, or they are, as it is commonly expressed, of three dimensions; but certain geometrical figures—viz. plane surfaces, plane curves, and straight lines—have the first only two dimensions, and the two latter properly speaking only one, though the form of plane curves cannot be determined without two dimensions, which are similarly requisite to determine the *position* of straight lines. We therefore assume, as we have said, three co-ordinate planes for the determination of material objects, &c.; but one plane and two lines in it, at right angles to each other, representing the intersections of the two other planes, are all that is necessary for plane surfaces, curves, and straight lines. For purely geometrical objects whose position in physical space we do not require to determine, the co-ordinate planes are not assumed as having any fixed position in that space. [COORDINATES.]

SPACE. In Music, the void between the lines in a musical staff. The spaces are four in number, and the lines five.

Space, Number, and Time. In Metaphysics. Matter as known to us, i. e. as it exists in so far as we are concerned, has always parts. We only know it either as a number of objects, forming parts of a great existing whole —the material universe—or as an object, one of these parts, itself the aggregate of a number of parts. As a whole, also, it is always known to us in a continual variation of state, in a constant change of condition and relation among its constituent parts. Our knowledge of it thus involves three distinct notions—*space*, *number*, and *time*. In their most elementary forms: *space* is the room in which more than one material object, or more than one part of a material object, exist, or, in other words, the room in which matter necessarily (i. e. only known to us as) extended does exist; *number* is the plurality or more-than-oneness of two or more material objects or two or more parts of a material object; *time* is the consecution or non-simultaneity of two states —conditions or relations of a material object. These are not *definitions* of space, number, and time; they add no clearness to our ideas of them; they are only verbal limitations of them to their elementary and primary forms as notions in the human mind. As such notions they are intuitive and cannot be defined, for that what is intuitive cannot be defined is a maxim in logic. Similarly in spiritual existence, as known to us, an intelligence can exist only as an aggregate of consecutive states, and this knowledge, apart from any knowledge of matter, involves the notions of number and time. Space, number, and time, then, are not existences per se; apart from material and spiritual existence we can form no notion of them. To us *extension* is a necessary quality of matter, and it underlies every notion of space, even in its primary form, while those secondary notions of it which we have, as a boundless void, as the distance between two material objects, &c., are, properly speaking, not notions of space, but of real or possible extension. Similar remarks apply to our secondary notions of number and time, which are respectively endless modifications of degrees of plurality, and of the number of changes of state or consecutions in any existence, the sum of which constitutes the duration of that existence. But whilst we cannot conceive the existence of space, number, or time, apart from the existence of matter or spirit, it is equally impossible for us to conceive the latter without the former; the two are indissolubly yoked together—though distinguishable, they are inseparable—we shall, therefore, call space a *conjugate* of material existence, and number and time *conjugates* of all existence both material and spiritual.

The question now naturally arises, Are the notions of space, number, and time, derived from our knowledge of existence, the results of our experience, or, far from being derived from that knowledge, are they not à priori necessary to its existence—elements of that knowledge supplied by the mind in which they are innate? The former is the doctrine of the empirical, the latter of the transcendental school, in behalf of which it has been maintained that, although we cannot prove directly that

these notions are innate, it is, on the other hand, absolutely impossible to prove that they are derived from experience without assuming in the proof the fact of their existence, the very proposition that we propose to prove—or without, as it is commonly called, begging the question. The error of the empiricists, it is urged, has arisen from their not attending to the difference between the elementary and primary notions of space, number, and time, which, and which alone, can be assumed to be innate, and the matured, complicated, and secondary notions – the elaborations of the primary by innumerable inductions and deductions—which we all have long before we are able to reason philosophically on the subject. One form of this error is the employment of the word *space* in its popular meaning of possible extension. Space not being an existence per se, but only a conjugate of material existence, cannot be said to be either finite or infinite, to have length or breadth, or depth, and for such a phrase as *infinite space* to be strictly and metaphysically correct, we should say 'the possibility of infinite extension,' or 'the possibility of infinite material existence.' But while this distinction should always be borne in mind in reasoning as to the notion of space being innate or empirical, it would be inconvenient and unnecessary to introduce such nicety into our arguments on what is generally called the infinity of space, and other similar subjects; while, in the cases of number and time, from the want of other terms to express their various meanings, we must simply be content with laying, and careful to lay, down their limitations when ambiguity would be likely to lead to error.

Sir W. Hamilton and his school, founding on Locke and Kant, have denied the possibility of our forming positive notions of the infinitudes of space, number, and time; but the incorrectness of this doctrine has been demonstrated by several recent authors, and the reader is referred to Mr. J. S. Mill's *Examination of Sir W. Hamilton's Philosophy* for a refutation of it.

Space, Physical. Physical space is the room in which the material universe (the cosmos) exists, or the measure of its extension. The question, therefore, of the existence of infinite physical space, is in reality that of the infinite extension of material existence, and cannot be solved directly, but only by analogy. The question whether, if the cosmos have only finite extension, space be still infinite, is not a physical but a metaphysical question; space meaning in this case not the measure of actual material extension, but the possibility of that extension. That portion of material extension with which we are immediately connected is, we have *learned* to know, continuous; i.e. there is no part of its containing space devoid of matter; the atmosphere which envelopes the earth and fills all the intervals between the objects on it having visible extension, being material, and capable, as such, of being felt, analysed, weighed, and even, though it is generally spoken of as invisible, *seen* under certain conditions. But the laws of the pressure of an elastic fluid, which it is, and of the action of the earth's attraction on it, have led many philosophers to the conclusion that at a certain distance from the earth's surface, about a hundredth part of its diameter, or nearly eighty miles, the atmosphere entirely ceases, and the question remains, Are the intervals between those apparently detached points of material existence, which we can perceive only by the sense of sight, absolutely void, or filled by a form of matter which we cannot so perceive? There are some reasons why we should suppose that they are so filled. The first is solely applicable to that portion of space which is occupied by the solar system. The bodies revolving round the sun are of two kinds: planets, whose density (i.e. whose mass in proportion to their magnitude) is considerable; and comets, whose density is often very small, i.e. whose magnitude is great, but whose mass is inconsiderable. Hence comets afford a more delicate test, as it were, of any possible resistance, than planets do; and Encke, from an elaborate discussion of the movements of a particular comet, announced that the acceleration of its motion was due to a resistance in space, the resistance of course increasing the sun's power over its mass. Such a medium must necessarily be of extreme tenuity.

Another reason for supposing space to be full of matter is not limited in actual deduction to the solar system only, and left to be applied analogically to the remainder—the immeasurably greater remainder—of the universe, but applies to all the universe that is known to us. It is this: All philosophers are now agreed that light is not a material substance, but an affection of matter; i.e. that without material existence light could not exist—without continuous material existence light could not be transmitted; a vacuum, a break in the continuity, would be an impermeable screen of darkness between a luminous object and an observer. A necessary inference from this is, that all space between the earth and the most remote star that has ever been observed from it, must be filled by a material medium by which the light of that star has been transmitted—that all the universe known to us is filled by such a medium. What is the nature, then, of this material packing of the universe? Is it one already known to us, or one that we must imagine only? One opinion is, that it is a peculiar substance called *ether*, specially adapted for the transmission of light, which not only pervades all the regions of space not occupied by any other material object, but also, in different degrees, other material objects, such as the atmosphere, glass, &c., producing the phenomena of transparency, translucency, and the like; and that it, and it alone, has the power of transmitting luminous undulations. Another opinion is, that the atmosphere which surrounds our globe is merely the condensation, due to the earth's

attraction, of a universal atmosphere which fills space and transmits the undulations of light without the assistance of any supplementary ether, as many other forms of matter transmit and otherwise deal with them. Of course, if this latter opinion be held, the opinion that the atmosphere *entirely ceases* at eighty miles from the earth's surface must be erroneous; and though the most delicate means that we possess would fail to detect any air at all above that height, it may still exist, just as well as an ether the existence of which we are as little able to ascertain experimentally. It has been objected to the theory of a universal atmosphere, that if it were true there would be a sensible atmosphere surrounding the moon, which, if it amounted only to the thousandth part of the density of the atmosphere of the earth, would be detected by certain astronomical observations. However, the atmosphere which would, on this hypothesis, be due to the moon's attraction, would be only of the density of the earth's atmosphere some six thousand odd miles above its surface, or nearly six thousand miles above the point at which it becomes utterly impossible for us to detect the existence of air by any means in our power.

The question of sensible atmospheres, i.e. atmospheres whose existence we can observe from the earth, surrounding the moon and the planets, on the supposition of a universal atmosphere, is so dependent on conditions, such as the temperature of the body, the nature of the matter of which it is composed, &c., of which we are and must always be ignorant, that no satisfactory answer to it can now be arrived at.

As to the infinity of physical space, or the infinity of actual material existence, all that we can say is, that however far we advance (and we have advanced a great deal) in the power of discerning distant objects, we have uniformly found new objects to discern, and we have, therefore, good analogical reason for supposing that no limit can be assigned to their still further existence. This view of what is commonly called the infinity of space is further supported by the fact that metaphysical space, as a conjugate of material existence, in no way precludes the possibility of its infinite extension.

Space Lines. In Printing, thin pieces of type metal, cast to various thicknesses and different lengths, and not so high as type, to put between and increase the width between the lines. They are generally called *leads*.

Space Rules. In Printing, fine lines, cast type high, generally cast to a 4-to-pica lead in thickness, and to any length required. They are used in setting up tabular matter.

Spacing. In Printing, the adjustment of the distance between the words in a line, so that there shall not be any glaring disproportion.

Spadaite. A hydrated silicate of magnesia, found in red translucent masses at Capo di Bove, near Rome. Named after Signor Spada.

Spadix. In Botany, a form of inflorescence in which the flowers are arranged around a fleshy rachis, and enclosed within a kind of bract called a *spathe*, as in Palms and Araceous plants.

Spahis or **Sipahis.** A part of the Turkish cavalry were so called. The word has the same derivation with Sepoy.

Spalacotherium (Gr. σπάλαξ, *a mole*, and θηρίον, *a beast*). In the Purbeck beds at Swanage have been found remains of a small insectivorous mammalian, which exhibits the character of having each of the teeth divided into three pointed cusps adapted for crushing the *elytra* (wing-covers) of the *Coleoptera* or beetles which abounded in the upper oolitic beds. The dentition offers most affinity to the extinct *Amphitherium* and *Dromatherium*, and the existing *Chrysochloris*.

Span (Ger. spanne). In ordinary language, this word signifies a measure taken from the space between the thumb and the middle finger, both being extended. In Architecture and Engineering, it is applied to the extent or spread of an arch between its piers or abutments.

Spanaemics (Gr. σπανός, *poor*, and αἷμα, *blood*). Medicines which are supposed by long-continued use to impoverish the blood.

Spandril (Ital. spandere, *to spread*). In Architecture, the space above the flanks, or the haunches of an arch, or vault, above the intrados, and not higher than the crown of the arch.

Spaniolite. A name given to the Grey Copper-ore containing quicksilver.

Spanish Chalk. A variety of Steatite or silicate of magnesia. It is also called *French Chalk*.

Spanish Juice. The extract of the root of the Liquorice, *Glycyrrhiza glabra*.

Spanker or **Driver.** The name of the gaff sail set on the mizen mast of a ship of three masts, or on the mainmast of a smaller vessel.

Spanner. An iron instrument used in the manner of a lever to tighten the nuts upon screws. There is usually a notch at either end of the spanner, to suit nuts and screw-heads of different sizes.

Spar (Ger. spath). A Mineralogical term applied to certain crystallised substances which easily break into cubic, or prismatic, or other fragments with polished surfaces; hence, also, the term *spathose*, applied generally to minerals of a sparry fracture. The term *spar* is commonly used by miners to denote crystalline quartz; by quarrymen it is applied indifferently to quartz and calcareous spar.

Spar, Fluor, or **Derbyshire.** Fluoride of calcium. [Fluor Spar.]

Spar, Heavy. Sulphate of Baryta. [Barytes.]

Spar, Iceland. Transparent rhombohedral carbonate of lime. [Iceland Spar.]

Spars. In Architecture, a term, now almost obsolete, denoting the common rafters of a roof, as distinguished from the principal rafters or other timbers.

Sparable Tin. A name given in Cornwall to small crystals of Tin-stone, from their imaginary resemblance to the particular kind of nail called a *sparable*. They are found at Huel Harris, Huel Owles, and elsewhere, near Camborne.

Sparoids. The name of a tribe of Acanthopterygian fishes, of which the genus *Sparus* is the type. The palate is edentulous, but the jaws are generally well armed with teeth: sometimes these are all of a conical form, adapted for killing and lacerating: sometimes they are all rounded and obtuse, fitted for bruising. In some species, the anterior teeth are shaped according to the laniary type, and the posterior ones are grinders; in others, the anterior teeth resemble the human incisors. The genera of Sparoid fishes are founded chiefly on these dental modifications.

Sparrow (A.-Sax. speara). The name commonly applied to the species of PASSER, Linn. (*Pyrgita*, Cuv.), which nestles upon buildings, and is termed *house-sparrow* (*Pyrgita domestica*).

Sparrow Hawk (A.-Sax. spearhafoc). The name of the *Falco nisus* of Linnæus, *Accipiter fringillarius* of Ray; which latter name is retained in modern ornithology for the subgeneric denomination of this small Raptorial bird.

Sparry Iron-ore or **Sparry Iron-stone.** Native carbonate of iron, composed (when pure) of 37·93 per cent. of carbonic acid and 62·07 protoxide of iron; but often containing admixtures of oxide of manganese, lime, magnesia, &c. This variety of iron-ore occurs in this country chiefly in Cornwall, and in the north-western parts of Devonshire and Somersetshire, where it is frequently associated with Copper Pyrites. A variety of crystalline forms may be noted at Fowey Consols, and at Buckler's Mine near St. Austell. In Styria, Carinthia, and the adjoining countries, Sparry Iron-ore forms extensive tracts, extending along the chain of the Alps into Austria on one side and into Salzburg on the other. Most of the Styrian steel is manufactured from the immense bed of ore which occurs at Erzberg between Eisenez and Vordernberg. At Samorostro in Spain, a hill, altogether composed of this ore, has been worked for ages.

Spartium (Gr. σπαρτίον, *a small cord*). The generic name of the well-known Spanish Broom, which differs from our native broom, *Sarothamnus*, in the calyx being split above, and thus having two lips instead of one. The plant is widely spread over the Mediterranean region, and has been cultivated in British gardens for upwards of three hundred years. The growth is like that of the common broom, but the green polished twigs are terete and rush-like, instead of angular. The handsome yellow pea-flowers, arranged in racemes at the ends of the twigs, are highly perfumed, and very attractive to bees.

By macerating the twigs a good fibre is obtained, which is made into thread in Languedoc, and into cord and a coarse sort of cloth in Dalmatia. The flowers are said to afford a yellow dye, and the seeds in large doses are emetic and purgative, and sometimes used in dropsy like those of the common broom.

Spasm (Gr. σπασμός, *a cramp*). An involuntary contraction of the muscles, generally attended by pain.

Spatangus (Gr. σπάταγγος). The name of a genus of *Echinidæ*, or sea-urchins, having the mouth situated laterally, and but four rows of pores.

Spathe (Gr. σπάθη). In Botany, a large and coloured bract situated at the base of a spadix, enclosing the latter, and supposed to perform the office of corolla.

Spathose Iron-ore. [SPARRY IRON-ORE.]

Spatulate (Lat. spatula, *a broad knife to spread salve with*). In Zoology, when a substance or part of an animal is flattened, and broader and rounder at the apex, narrow at the base.

Spawn. In Natural History, this term is commonly applied to the eggs or ova of those oviparous animals which exclude them in a mass, either separate, as in most osseous fishes, or enveloped in an albuminous covering, as in frogs, toads, and many molluscs.

Speaker. The presiding officer in each house of parliament is so termed.

In the House of Lords, the lord chancellor or lord keeper of the great seal acts as Speaker; but, if there be no such person, the crown may appoint a Speaker by commission. At all times there are deputy Speakers appointed by commission to officiate during the absence of the Speaker, and if there be no Speaker or deputy Speaker, or none present, the House may elect. The Speaker of the House of Lords is not necessarily a peer, and in several modern instances (as in the case of Sir Frederick Thesiger, March 1, 1858) a lord chancellor has sat as Speaker before his creation as a peer. The Speaker of the House of Lords puts the question and transacts other formal business, but he has no more authority in keeping order or controlling the debates than any member of the House, the appeals on points of order being always made to the Lords present, generally. He may (if a peer) speak and vote, but he has no casting vote; in case of equality of division, the non-contents prevail.

In the House of Commons, the office of Speaker is of much more importance than in the Lords. The Speaker is chosen by the Commons at the desire of and subject to the approbation of the crown, and in rank takes precedence of all commoners. He presides over the deliberations of the House and enforces order. As *mouth of the House*, he communicates its resolutions to others, conveys its thanks, and expresses its censure. He issues warrants

to execute the orders of the House for the commitment of offenders, for the issue of writs, for the attendance of witnesses, and for other purposes, and transacts a great variety of other formal business. The Speaker cannot speak or vote except in committee (when he is out of the chair) or in case of an equality of votes, when he exercises the privilege of giving a casting vote. He has been enabled by statute to issue warrants to make out writs for new elections during a recess. Formerly there was no regular provision for the absence of the Speaker, and various expedients had been adopted on occasions of his indisposition, but a deputy Speaker may now be appointed. (Stat. 18 & 19 Vict. c. 84.) (May's *Parliamentary Practice.*) [PARLIAMENT.]

Speaking Trumpet. [TRUMPET.]

Spear (Ger. speer, Lat. sparus). A weapon consisting of a pointed blade at the end of a long shaft. It is one of the earliest known weapons.

Special Case. In Law, the statement, in a compendious form, of the facts upon which any question of law or equity arises for the purpose of obtaining a judicial decision thereon. This may be done in many cases both at common law and in chancery, when there is no dispute as to the *facts*, and the only contention between the parties relates to a matter of law or equity.

Special Constables. Constables appointed for particular occasions, as to execute a warrant or to assist in preserving the peace. (41 Geo. III. c. 78; 1 & 2 Wm. IV. c. 41; 5 & 6 Wm. IV. c. 43.)

Special Jury. A jury consisting of persons of a certain station in society, as esquires or persons of higher degree, or bankers or merchants. (3 Steph. *Comm.* 617.) [JURY.]

Special Pleader. In Law, one who draws common law pleadings. [PLEADING.] The term is particularly applied to persons who devote themselves to that line of practice without being either attorneys or barristers. They are compelled by statute to take out an annual certificate similar to that taken out by attorneys.

Special Verdict. A finding by the jury of the naked facts of the case, leaving to the court the application of the law, on which the ultimate entering of the verdict for one side or the other may depend.

Specialty. In Law, any instrument in writing under seal. Specialty creditors are those who have their debts secured to them by deed, in opposition to creditors on simple contract. The advantages of the former security are, that it has priority in the distribution of assets in some cases, and that specialty debts in general are not extinguished by the Statute of Limitations, until the lapse of twenty years, whereas simple contract debts are extinguished in six years.

Specie. A term used for gold and silver coin, in contradistinction to *paper money*.

Species (Lat.). In Logic, a predicable which is considered as expressing the whole essence of the individuals of which it is affirmed. The essence of an individual is said to consist of two parts: 1. The material part, or genus; 2. The formal or distinctive part, or difference. The genus and difference together make up, in logical language, the species. It is obvious that the names *species* and *genus* are merely relative; and that the same common terms may, in one case, be the species which is predicated of an individual, and in another case the individual of which a species is predicated: e.g. the individual, Cæsar, belongs to the species man; but man, again, may be said to belong to the species animal, &c., as we contemplate higher and more comprehensive terms. A species, in short, when predicated of individuals, stands in the same relation to them as the genus to the species, and when predicated of other lower species, it is then, in respect of these, a genus, while it is a species in respect of a higher genus. Such a term is called a *subaltern species* or *genus*; while the highest term of all, of which nothing can be predicated, is the *summum genus*; the lowest of all, which can be predicated of nothing, the *infima species*. The difference which, together with the genus, makes up the species, is termed the *specific difference*. [LOGIC; PREDICABLE.]

SPECIES (Lat.). In Natural History, certain groups of individuals, continued or reproducible, with characters, as far as human knowledge of them extends, so fixed as to be specified, are called, in Mineralogy, Botany, and Zoology, *species*.

The definition of such species varies in those three kingdoms of nature; nor has any been proposed which is equally applicable to the different grades of organisation manifested in the series of animals and of plants.

The 'distincta propagatio ex semine' of Ray reaches a long way down, but not to the bottom of the vegetable kingdom.

'The sum of organisms born the one of another, or of common parents, and of all such as resemble their parents as much as they resemble one another,' is applicable to the vast proportion of the Règne Animal known to Cuvier; but many exceptions to his definition of a *species* have since been brought to light.

Lamarck's more concise definition, as 'a collection of like individuals, produced by other individuals equally like them,' is equally affected by the phenomena of parthenogenesis. Cuvier, indeed, qualifies his definition by stating: 'Although organisms produce only bodies similar to themselves, there are circumstances which, in the succession of generations, alter, to a certain point, their primitive form.' (*Tableau Elèmentaire de l'Histoire Naturelle des Animaux*, 8vo. 1798, p. 9.)

One main aim of his successors is, and long will be, to determine that point; or whether there be, indeed, any such at which the mutation of a species necessarily stops. The observed grades of departure from specific type are termed *varieties*, and the degree of variation

in the offspring from the parent appears to be greatest in the lowest organisms. Consequently the definition or recognition of a *species* of Foraminifer, or Brachiopod, e.g., is much less easy than of a bird or a mammal.

Scanty observations on highly organised animals had shown that, when a male and female of different kinds interbred, the hybrid offspring were less fertile in some instances than in others. Thus the offspring engendered between the two kinds of equine animal, called *horse* and *ass*, being barren as a rule, was called a *mule*; and the parents were determined to be *species* under the names *Equus caballus* and *Equus asinus*. The hybrids produced from dog and jackal were found to be fertile (at least in a greater degree) inter se, and accordingly were pronounced to be *varieties*. There is evidence, indeed, that the dog, or some dogs, have been derived from jackals.

In proportion to the degree of man's sovereignty over lower species, is the number and kind of varieties which he obtains from them.

Food diversified in kind and abundance; *medium of existence* more or less cold, or more or less moist; degrees of exposure to *light*; vestures added to natural clothing; modifications of *exercise*; and limitations of *locomotion*, are among the causes of varieties defined by Cuvier, and of which he points out their respective effects. To these influences, man adds the more efficient one of selecting varieties, however produced, to breed from. The range of such departures from the primitive or wild type seems much greater than in the series of the wild species of a genus. But the breeds of dog, horse, ox, sheep, pigeon, fowl, so produced, are fertile inter se.

Many observations make it probable, but more are needed to prove, that, when freed from man's thraldom and care, such breeds or varieties die out or revert to the primitive type.

The inherent capacity of an animal for modification varies in different species.

To whatever degree, under the above-named influences, it attains, such changes of form and structure induce corresponding changes in action: the more frequent employment of certain parts or organs usually leads to a proportional increase of size in such parts; and, as the increased exercise of one part is usually accompanied by a corresponding disuse of another part, such disuse, by inducing a degree of atrophy, concurs with the opposite in forming another element in the mutation of organic forms. Next follows the hereditary tendency to transmit to offspring characters of variation acquired by the operation of external and internal influences on the parents. Finally, is to be added the occurrence, in offspring, of parts, proportions, or powers not traceable to any of the above influences upon parents, and called *accidental varieties*, proceeding, in some instances, to such degrees of departure from specific type as to have received the name of *malformations* and *monstrosities*. The influence of the above various conditions in the origin of species, with the postulate of illimitable time for their continued operation, forms a characteristic part of the work by Lamarck entitled *Philosophie Zoologique*, 8vo. 1809.

The principles, based on rigorous and extensive observations, which have been established since that date, and which have impressed upon the minds of the most exact reasoners in biology the conviction of a constantly operating secondary law originating species, are the following: the principle of irrelative or vegetative repetition, as manifested in lower organisations; unity of type, as exemplified by the power of determining homologous parts; the analogies of transitory embryonal stages in a higher animal to the matured forms of lower animals; the phenomena of parthenogenesis; the progressive departure from type, or from a more generalised to a more specialised structure, exemplified in existing species forming ascending steps in the scale of life, and also in the series of extinct species as they successively approach in time to the neozoic fossiliferous beds.

Owen, admitting, in 1849, that the succession of such species was due to the operation of natural laws or secondary causes, owns his ignorance of their nature or mode of operating in the production of species. (*On the Nature of Limbs*, 8vo. p. 86.) The author of the *Vestiges of Creation*, impressed by the results of embryological investigations since the time of Lamarck, speculates on the influence of premature birth, or of unduly prolonged fœtation, in establishing the beginning of a new specific form; and, in the main, inclines to inherent proneness to deviate from rule or pattern as a more potent cause of specific change than the influence of volitions or of outward circumstances.

The different degrees in which these circumstances operate on the different species or individuals subject thereto, attracted the consideration of naturalists in reference to the instances of extinction of species, progressively, and of late rapidly, brought within their cognisance. The study of this difference engendered the idea or perception of a 'contest for existence' being ever waged by species. Thus, in his account of the gigantic wingless birds of New Zealand, Prof. Owen, in 1850, expressed himself as follows: 'In proportion to its bulk is the difficulty of the contest which, as a living organised whole, the individual of such species has to maintain against the surrounding agencies that are ever tending to dissolve the vital bond and subjugate the living matter to the ordinary chemical and physical forces. Any change, therefore, in such external agencies as a species may have been originally adapted to exist in, will militate against that existence in a degree proportionate, perhaps in a geometrical ratio, to the bulk of the species. If a dry season be gradually prolonged, the large mammal will suffer from the drought sooner than the small one; if such alteration of climate affect the

quantity of vegetable food, the bulky herbivore will first feel the effects of stinted nourishment; if new enemies are introduced, the large and conspicuous quadruped or bird will fall a prey, whilst the smaller species conceal themselves and escape. Smaller animals are usually, also, more prolific than larger ones.

'The actual presence, therefore, of small species of animals in countries where larger species of the same natural families formerly existed, is not the consequence of any gradual diminution of the size of such species, but is the result of circumstances which may be illustrated by the fable of the "oak and the reed;" the smaller and feebler animals have bent and accommodated themselves to changes which have destroyed the larger species.'

The field of observation thus opened, by such instances of *natural rejection* of species, was one rich in the relations of outward circumstances and influences, not only in the preferential conservation of species, but in the fostering and favouring of varieties.

Baden Powell, admitting the influence of external conditions acting unfavourably, so as to cause the declension or extinction of a species, remarks: 'It is therefore a fair inference that, if favourable conditions were continued, and the variety were locally isolated from the rest of the species, it would become a permanent type or species.' (*Unity of Worlds*, 12mo. 1855, p. 376.)

Mr. Wallace, in 1858, assuming that varieties do arise in a wild species, speculates similarly on the influences which may either tend to the destruction of such variations from a specific type or to their adaptation to changes in surrounding conditions, under which they might be better calculated to exist, than the type form from which they had deviated. Arguing against the partial and inadequate views of Lamarck's hypothesis of the transmutation of species commonly given in popular English works or compilations, as Lyell's *Principles of Geology*, e.g., Mr. Wallace remarks: 'The powerful retractile talons of the falcon and the cat tribes have not been produced or increased by the volition of those animals; but among the different varieties which occurred in the earlier and less organised forms of these groups, those always survived longest which had the greatest facilities for seizing their prey.'

'Neither did the giraffe acquire its long neck by desiring to reach the foliage of the more lofty shrubs, and constantly stretching its neck for the purpose, but because any varieties which occurred among its antetypes with a longer neck than usual at once secured a fresh range of pasture over the same ground as their shorter-necked companions, and on the first scarcity of food were thereby enabled to outlive them.' ('On the Tendency of Varieties to depart indefinitely from the Original Type,' *Proceedings of the Linnean Society*, Aug. 1858, p. 61.)

Mr. Darwin expresses this view by the term *natural selection*, not as contrasted with the *natural rejection* instanced in a previous illustration, of which he seems not to have been aware, but with the *artificial selection* of breeds and varieties of domesticated species by man. The following is one of the illustrations of his idea. 'To give an imaginary example from changes in progress on an island: let the organisation of a canine animal which preyed chiefly on rabbits, but sometimes on hares, become slightly plastic; let these same changes cause the number of rabbits very slowly to decrease, and the number of hares to increase. The effect of this would be that the fox or dog would be driven to try to catch more hares; his organisation, however, being slightly plastic, those individuals with the lightest forms, longest limbs, and best eyesight, let the difference be ever so small, would be slightly favoured, and would tend to live longer, and to survive during that time of the year when food was scarcest; they would also rear more young, which would tend to inherit these slight peculiarities. The less fleet ones would be rigidly destroyed. I can see no more reason to doubt that these causes in a thousand generations would produce a marked effect, and adapt the form of the fox or dog to the catching of hares instead of rabbits, than that greyhounds can be improved by selection and careful breeding.' Many other ingenious conjectures are advanced in the work entitled, *On the Origin of Species by means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life*, 8vo. 1859, in which the author states: 'The varieties or incipient species thus produced ultimately become converted, as I believe, into new and distinct species.'

As to the mode of operation of the converting cause, there is, at the bottom, much affinity of thought between Darwin and Lamarck. 'In North America the black bear was seen by Hearne swimming for hours with widely open mouth, thus catching, like a whale, insects in the water. Even in so extreme a case as this, if the supply of insects were constant, and if better adapted competitors did not already exist in the country, I can see no difficulty in a race of bears being rendered, by natural selection, more and more aquatic in their structure and habits, with larger and larger mouths, till a creature was produced as monstrous as a whale.' (*On the Origin of Species*, 1st edit. 1859, p. 184.)

Here, therefore, *internal impulse* is associated with *external circumstance*, abundance, viz., of attractive food, to illustrate the powers in nature which tend to select a form or variety for a transmutation of species. But actual observation leads to a recognition of a cause distinct from both *impulse*, *habitual action*, *change of the ambient medium*, or *external influence* of any kind. 'L'espèce est fixée sous la raison du maintien de l'état conditionnel de son milieu ambiant. Elle se modifie, elle change, si le milieu ambiant varie.' (Geoffroy St. Hilaire, 'Etudes Progressives,' *Mémoires de l'Acad. des Sciences*, t. xii. 1833.)

Taking the whale-kind as now known to zoologists, e. g., they seem to exemplify grada-

tional steps by which extreme modifications of cetacean structure, especially in the skull and dentition, are reached.

But such instances of freedom from the trammels of family likeness seem to be independent of external influences. The ocean has none of those diversities of condition which the dry land shows, and is exempt from the few which, in fresh waters, may be invoked to account for varieties in the species of fish. It is true that the trout (*Salmo fario*) of the mountain streamlet is small, while that of the wide river or wider lake is large; but no such differences in the theatre of life can be invoked to explain the origin of the dwarf porpoise or the giant whale—both have alike the unlimited seas for their range. The external conditions that could *select* the maxillary wall of the circum-narial basin in *Hyperoodon*, *Physeter*, or *Platanista*, are equally inconceivable. But the occasional departure from parental type, manifested by what at first might be called a *monstrous* proportion of the nasal or facial plate of the maxillary, may accord with the idea suggested by the observed steps in a gradation of such deviating developements.

If we were able to trace the successive steps backward in the formation, or creation by preordained law, of the species of *Cetacea* which now respectively propagate their kind, we might arrive at the primitive generalised form whence those species had diverged, and be able to determine whether such cetacean type had ascended from a marine reptile, or retrograded, as in Mr. Darwin's view, from a terrestrial mammal.

The tendency to such speculation is inevitable: the question of the first origin of living things will suggest itself in speculating on the origin of species.

Buffon supposed that certain type-forms were, at first, miraculously created, and that most of the so-called *species* exemplified degenerations from such originally perfect types: applying this view to the two hundred Mammalian species so well and eloquently described in his great work, *Histoire Naturelle générale et particulière*, &c. 4to. 1749–1789, tom. xiv. p. 328) he reduced them to about fifteen primitive stocks; but admitted also certain isolated created forms, which represented both species and genus.

Mr. Darwin, equally invoking a cause distinct and above any natural law, reduces its operation to narrower limits. 'I believe,' he writes, 'that animals have descended from, at most, only four or five progenitors, and plants from an equal or lesser number.' But he adds that 'analogy would lead us one step further, namely, to the belief that all animals and plants have descended from some one prototype,' and thus, 'that probably all the organic beings which have ever lived on this earth, have descended from some one primordial form into which life was first breathed.' (*Op. cit.* p. 486.) The idea of the direct creative act, so restricted, would appear to be that 'certain elemental atoms have been commanded suddenly to flash into living tissues.' (*Ib.*)

At this stage of speculation as to the origin of species, Lamarck is more logical, and his hypothesis more in accordance with the observed actual or existing grades of organised beings.

Lamarck reduces the prototypes of animals to two forms—the *vibrio* and the *monad* (*vers et infusoires*). The influences which operated though time unlimited led from one prototype though the molluscous, from the other through the articulate series, to the several forms of fishes; and thence, through the well-defined vertebrate pattern, up to man. With philosophic consistency, Lamarck sums up: 'Cette série d'animaux commençant par deux branches, où se trouvent les plus imparfaits, les premiers de chacune de ces branches ne reçoivent l'existence que par génération directe ou spontanée.' (*Phil. Zool.* vol. ii. p. 463.)

Every chemical constituent of cell-organisms (*Protozoa*) is found in the mineral kingdom.

Decomposition of mineral species, with water, supplied the first protoplastic matter, which, under the influence of light and heat, and by the conversion of electric, magnetic, or chemical, force into the vital mode, became aggregated into the form of the *cell*.

Organisms having thus originated, decomposition is but the transition from one life to another.

Nothing larger than the microscopic monad, or more complex than *sarcodé*, is produced by *heterogeny*. All higher organisms are derivatives of these.

If it be admitted that the sum of present evidence sways in favour of the becoming of species through the operation of actual powers, we may suppose that provision has also been made for the origination of those germs or germ-like organisms from which the higher species are derived. The nature of that provision, or the mode and conditions of operation whereby protoplasmic organic mucus becomes monadic, may worthily occupy the attention of microscopic observers and chemists.

The question now is a moot one between the heterogenists and the panspermists or those who hold that the germs of every kind of microscopic organism float in the atmosphere and develope in the infusions into which they may fall.

Specific. In Medicine, this term is applied to remedies the effects of which upon particular diseases are little liable to fallacy and uncertainty; hence cinchona is called a specific in certain kinds of intermittent fever, and mercury in syphilis, &c. A *specific character* is that which peculiarly and certainly distinguishes one thing from another.

Specific Gravity. [GRAVITY.]

Specific Heat. [THERMOTICS.]

Specific Performance. One of the main circumstances which led to the growth of the jurisdiction of the Court of Chancery was the power assumed by the chancellors to direct agreements to be performed, specifically, while

the common law courts would only give damages for the breach or non-performance of them, and this distinction still continues to exist in most cases. The Court of Chancery, however, will not decree specific performance of agreements, which it cannot conveniently superintend, such as contracts to construct buildings or works. A limited jurisdiction to order specific performance of agreements has recently been conferred on the county courts.

Specification. In Law, this term is especially used to signify the detailed description of an invention which it is sought to secure by a patent: this must be filed in Chancery and is open to public inspection. [PATENT, LAW OF.]

Spectacles (Lat. spectaculum, *a show* or *sight*, not *that which aids the sight*). An optical instrument, consisting of two lenses set in a frame, for assisting or correcting the defects of imperfect vision. The lenses are convex or concave, according to the nature of the defect to be remedied. In old age the form of the eye becomes flat, and the rays of light are consequently not refracted sufficiently in passing through it to meet on the retina and produce distinct vision. This defect is remedied by a convex lens, which produces a slight convergency of the rays before they enter the eye. Short-sighted people, on the contrary, require concave lenses; because, in their case, the indistinctness of vision proceeds from too great a curvature of the anterior portion of the eye, which causes the rays to meet in a point before they reach the retina—a defect which is remedied by giving the rays a slight divergency before they enter the eye.

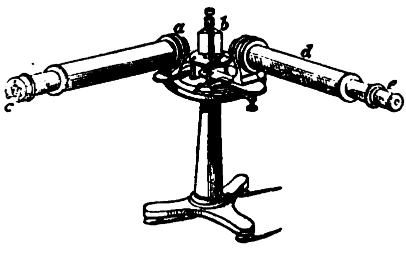
Spectacles appear to have been first used about the latter end of the thirteenth century; but the date and author of the invention are not certainly known, and have been much disputed. It seems most probable that the first hint of their construction and use was taken either from the writings of Alhazen, who lived in the twelfth century, or of Roger Bacon, who died about 1292. A passage in the *Opus Majus* of the latter renders it certain, at least, that he was acquainted with the use of crystalline lenses in magnifying minute or distant objects. (Smith's *Optics*, 'Remarks,' art. viii. 5—90.)

Spectre. In Zoology, a species of four-handed mammal (*Lemur spectrum*, Linn.), so called on account of its nocturnal habits, attenuated frame, long and skeleton-like limbs, and the gliding, stealthy, noiseless motion, by which it surprises a sleeping prey.

Spectroscope. One of the most powerful and important instruments of modern research, in which the analysis of light coming from various light sources is conducted by means of prisms.

If we allow a beam of light to fall on a prism at a proper angle, and if we examine the emergent ray with the naked eye, or let it fall on a plain white surface, we shall find that the ray has been refracted and analysed by its passage. If we wish to observe this phenomenon under the best possible conditions, we shall take care that the incident ray is small and *parallel*, and we shall examine the emergent rays by means of a telescope. The parallelism and reduction of the ray to a fine line is managed by an object-glass (a) near the prism (b), with a very fine slit (c) at its focus, the whole of this arrangement resembling a telescope. The tele-

Fig. 1.



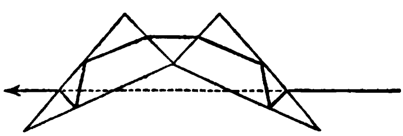
scope (d), by means of which the emergent ray is observed, may have its eye-piece (e) armed with a micrometer, if necessary, for observing the bright lines or dark bands in the spectrum. [SPECTRUM ANALYSIS.]

It will be seen from the figure that if one prism be used in this manner, the two telescopes will form an angle between them. This is the ordinary construction, but for some purposes it is convenient that they should have a common axis. Steinheil has constructed a spectroscope of this kind, in which three prisms are used, the direction of the ray being kept by means of external reflections. Hoffmann has constructed a differential prism with the same end in view. The best form of this kind is the *Herschel-Browning*, the principle of which will be easily seen from fig. 2. It is, in fact, a combination of two direct vision prisms, the smallest angle being determined by the formula—

$$2\,A = 1 - \frac{1}{\mu^2},$$

μ being the refractive index of the glass employed.

Fig. 2.



In fig. 1, we have supposed *one* prism only to be employed, but it is now usual to employ several, the rays being more opened out by each passage, so that a gradually increasing dispersion is obtained. In the instrument manufactured by Mr. Browning for the Kew Observatory, which is now employed in mapping the lines in the solar spectrum with a degree of perfection surpassing anything hitherto attempted, no less than nine prisms are used.

The dispersion may be also increased by using substances having a higher refractive

index than glass. Bisulphide of carbon is the substance usually employed; and as it is a highly volatile liquid, it is enclosed in hollow glass prisms.

In order to obtain the bright lines on the spectrum of the light emanating from any substance, the flame of a common spirit lamp, or a gas jet known as a *Bunsen's burner*, is placed before the narrow slit or knife edges. A small bead of the substance to be experimented on may be fused into a small loop of platinum wire. The wire being attached to a convenient support, the head should be brought to the front edge of the flame.

Some of the most important astronomical discoveries of the last few years have resulted from the application of the spectroscope to the telescope, the aid of the latter being called in to collect the light emanating from the distant stars and nebulæ. The light incident on the prism is rendered parallel, as in the ordinary arrangement, and the emergent rays are observed in the same manner, but a further refinement is required in this case. The image of a star formed at the focus of a good telescope is almost a point; its spectrum, therefore, would be a line, and in such a spectrum it would be impossible to distinguish any of the characteristic features. The point, therefore, is elongated somewhat at right angles to the plane of refraction by means of a cylindrical lens.

Messrs. Sorby and Browning have also arranged a modification of the spectroscope for use with the microscope. It is applied to the eye-piece of that instrument by means of direct vision prisms. It is applicable to opaque objects, and may also be applied beneath the stage. By its means the spectrum of the smallest object, or a particular portion of any object, may be viewed with the greatest precision and ease.

Spectrum (Lat. *an image*). In Optics, the name given to the luminous band produced on a screen or in the eye by subjecting a beam of light received through a small slit or hole, to decomposition by a prism. For the different colours and fixed lines visible in different spectra, see CHROMATICS; COMET; NEBULÆ; SPECTRUM ANALYSIS; STAR; and SUN; and for the refrangibility of the different rays, REFRACTION.

Spectrum Analysis. Every known substance gives out light if it be sufficiently heated. Daylight is supplied from the intensely heated matter of the sun; the artificial light of gas, oil-lamps, candles, &c., is emitted by white-hot particles of carbon; the luminosity even of lightning arises from the highly ignited nitrogen and oxygen of our atmosphere.

Light from various sources differs considerably in composition. The unaided eye is unable to detect differences of colour in the associated mass of rays that impinge upon the retina; it is only when that mass or pencil of rays is first passed through a prism that the eye can ascertain what particular rays are present and what absent. The prism has the power of decomposing a compound ray into its constituent rays; it bends each constituent ray out of its course to an unequal extent, so as to arrange them consecutively in a band. This band is called a *spectrum*. Thus a beam of sunlight is found to consist of rays of almost every conceivable shade of colour, the spectrum beginning with red, which is least bent out of its course, or least *refrangible*, passing through every tint of orange, yellow, green and blue, and terminating in violet rays which are the most refrangible. This spectrum of sunlight has long been familiar to us under other names. Thus, the pretty coloured appearances sometimes seen on the wall, ceiling, floor, and furniture of a room when the sun shines on the prisms of an ornamented glass chandelier are the spectra of beams of sunlight; the white rays are decomposed by the prisms and the thereby disassociated rays reflected from the objects in the room. Received directly into the eye, the effect is still more gorgeous. But the most magnificent spectrum that we are acquainted with, a combination, so to speak, of innumerable spectral bands placed side by side, is that which occurs when rain-drops are the reflecting and refracting media—the familiar but ever-glorious rainbow.

Thus, then, a prism has the power of analysing light, showing what are its constituent rays; the latter being termed a *spectrum*. The operation is that of *spectrum analysis*. But it is analysis in a more extended sense, for every element of our earth gives, when its vapour is ignited, rays which probably are peculiar to itself; if, therefore, a substance of unknown composition is intensely heated, and the light which it emits is examined by a prism, the colour and position of the rays which may be present indicate at once the composition of the substance.

This statement must, however, be somewhat qualified. Every element that has been examined certainly has a characteristic spectrum, but many have yet to be examined. Again, temperature seems to influence considerably the character of a spectrum. The spectrum of a compound containing two or more elements has been proved to be different from the spectra of its constituents if the compound be not decomposed by the heat applied. And, lastly, a method has yet to be devised by which a substance shall be so ignited that every element which it contains shall be vaporised with certainty, and the emission of light from it be sufficiently continuous to admit of practical recognition of its spectrum.

Four new metals have been discovered by spectrum analysis. Bunsen and Kirchhoff, in examining the spectra of certain residues of the evaporation of water from a spring (Durckheim), detected rays of a colour and position in the spectrum hitherto unobserved. Following up the research, they succeeded in isolating the two metallic elements cæsium and rubidium. Soon afterwards Mr. Crookes discovered thallium; indium being the last added to the list in this way.

Spectrum analysis has also thrown considerable light on the question of the constitution of the universe, new facts having been acquired concerning the sun, stars, nebulæ, and comets. Thus, to begin with the sun, the spectrum of sunlight, otherwise bright and brilliant throughout its whole extent, is separated into distinct parts by a large number of exceedingly narrow spaces apparently devoid of light. The appearance of this spectrum when thrown directly on the retina or reflected from a surface is that of light of all colours, from red to violet, traversed by numerous fine lines in a direction transverse to its length. Now, it is remarkable that the spectra of several of the elements are composed of bright rays identical in position with these dark spaces in the solar spectrum. The key to the interpretation of this fact has been obtained experimentally and is as follows: The light emitted by an incandescent body is sifted by passage through any ignited vapour, the ray or rays sifted out being precisely those which the ignited vapour itself emits. So, then, the light emitted by the photosphere of the sun is absorbed by the vapour of various substances in the sun's atmosphere, the only perceptible light which reaches our earth being that not so absorbed. The dark spaces in the solar spectrum being identical with the light emitted by certain ignited terrestrial metals, the inference is that the vapours of those metals exist in the sun's atmosphere. So far as examination has at present extended, these metals are ten in number, viz. sodium, potassium, magnesium, iron, chromium, nickel, calcium, barium, copper, and zinc. Hydrogen is also present in the solar atmosphere. This magnificent discovery is due to Kirchhoff. The analysis of starlight has shown that the stars are built on the same model as the sun, though the details vary in each star yet examined. The light of nebulæ and comets shows us, on the other hand, that those bodies are masses of glowing gas.

Speculation (Lat. speculatio, from speculor, *I watch*). In Commerce, a term employed, with some slight meaning of disapprobation, to designate such purchases as are made in hope that there will speedily be a rise in the price of the article bought, and thereupon a gain to the buyer. Speculation, then, is an anticipation on the part of a trader that demand will be excessive or that supply will be deficient. The former is the commonest cause of speculation and is generally the most liable to fallacy, since it is founded on the interpretation of the inclinations which affect others, or the powers which they possess of gratifying these inclinations, while the latter is more frequently founded on facts. Thus, for instance, in the early days of the gold discoveries in Australia, speculation took the form of exports to that region, and so excessive was the tendency and so great the glut that articles were frequently sold at less than the cost of freight; on the other hand, the speculative purchases of cotton during the continuance of the great American war were based on the anticipation of deficient supply, and were on the whole successful.

The function of the speculator, on the presumption that his action is governed on common prudence, and by as much foresight as possible, is, on the whole, beneficial to society. In appearance, he is at war with the general interests of mankind; in effect he serves them. He renders prices generally steady by his eagerness to buy when prices are low, and he enforces economy by withholding a portion of consumable commodities when scarcity occurs. In past times, the tendency to speculate in such commodities was checked by severe statutes, and it was only when these indirect advantages were detected that these repressive laws were repealed. Thus, Sir John Barnard's Act, passed about the middle of the last century, strove to prevent time bargains on the Stock Exchange, by disabling those in whose favour the bargain had turned out from recovering against the loser by legal process. The brokers met this disability by establishing a strict code of honour. But the public has gradually learned that these negotiations are of considerable utility by obviating the risk of great fluctuations in the price of securities. Of course this action of speculators is quite distinct from the occasional attempts made to force a panic in some stock or shares by the offer of fictitious sales. The most notable of these operations for a rise or fall, were the South Sea Bubble, the Mississippi scheme, and the tulip mania in Holland.

When the speculator purchases consumable articles on credit, his demand raises prices early, and, if his conjecture be correct, only anticipates a certain rise. Should his judgment be in error, he bears the loss; and if many speculators join in the same or similar ventures, the reaction involves an increased demand for bank credit. Speculative purchasers do not therefore, as some economists have supposed, increase the amount of convertible bank-notes, but sales consequent on the reaction do. This fact is of great importance in the theory of banking.

Speculum (Lat. *a mirror*). In Optics, the term *speculum* is usually appropriated to reflectors formed of polished metal; while the term *mirror* is used to signify a reflector of glass. For the focal distances and laws of reflexion of spherical specula, see REFLEXION; and for a description of the method of casting and polishing large specula for reflecting telescopes, see Sir W. Herschel's description of his telescope in the *Phil. Trans.* for 1795; Brewster's edition of Ferguson's *Lectures*; and the article 'Telescope' in the *Encyclopædia Britannica*. [TELESCOPE.]

Speculum Metal. Speculum metal, with which mirrors for reflecting telescopes are made, is an alloy of two parts of copper and one of tin; its whiteness is improved by the addition of a little arsenic.

Speech. [LANGUAGE; METAPHOR; POLYONYMY; SYNONYMY.]

Speed of Railway Trains. [RAILROADS.]

Speed of Steam Vessels. [STEAM NAVIGATION.]

Speeton Clay. A dark blue laminated clay with calcareous nodules, found near Scarborough in Yorkshire, belonging, it is believed, to the lower part of the cretaceous series. It contains fossils.

Speiss. An impure arsenide of nickel, obtained from the ores of cobalt and nickel in smalt-works.

Speldings. A Scotch term for dried and salted whitings.

Spell (A.-Sax. spel, *story* or *tale*). Any form of words, written or spoken, supposed to be endowed with magical virtues.

Spelt (A.-Sax. spelte, Ger. spelz). The *Triticum Spelta*, an inferior kind of wheat grown in some parts of the European continent.

Spelter (Dutch spiauter). The commercial term for zinc. [PEWTER.]

Sperm-cell. In Anatomy, the cells contained in the liquor seminis, in which are formed the spermatoa, or cells of developement of the spermatozoa.

Spermaceti (a word coined from the Gr. σπέρμα, *seed*, and κῆτος, *a large fish*). This substance concretes or crystallises spontaneously out of the oil of the spermaceti whale. It is purified first by pressure, then by fusion and boiling with a weak alkaline ley. When melted in masses, it concretes in crystalline plates of a silvery lustre and unctuous feel. It fuses at about 100°. It dissolves in boiling alcohol; and as the solution cools it separates in brilliant scales, to which Chevreul has given the name of *cetine*. Spermaceti differs from common fats in not yielding glycerine when saponified, but a peculiar base termed *ethal* $= C_{32}H_{34}O_2$.

Spermaceti Whale. [CACHALOT.]

Spermatic Chord. That part which, in Mammals having a SCROTUM, seems to suspend the testicles, and, in fact, contains their vessels, nerves, and ducts, with the surrounding muscular and connective tissue.

Spermatic Fluid. [SPERMATOZOA.]

Spermatoa (Gr. σπέρμα, and ᾠόν, *an egg*). The cells which stand in the relation of nuclei to the sperm-cells, and of developemental cells to the spermatozoa. Sometimes the sperm-cell contains a single spermatoon, sometimes several spermatoa, in which case the resulting spermatozoa often unite together and form a fasciculus, as, e.g., in the sparrow.

Spermatophora (Gr. σπέρμα, and φέρω, *I carry*). In Anatomy, cases of albuminous matter, in which the bundles of spermatozoa are packed; they are largest and most complex in the Cephalopods.

Spermatozoa (Gr. σπέρμα, and ζῶον, *animal*). The filamentary bodies developed in the semen, and consisting of an enlarged extremity called *body*, and a vibratile filamentary appendage called *tail*. Spermatozoa consist of an amber-coloured, highly refracting, homogeneous substance, like the hyaline nucleus of cells, and are formal modifications of the nucleus of the spermatoon. They are essential to impregnation.

Spermidium (Gr. σπέρμα). A kind of small seed-vessel, resembling a seed, and more commonly called an *achene*.

Sphacelus (Gr. σφάκελος). [GANGRENE.]

Sphaeristerium. [BALL.]

Sphaerosiderite or **Spherosiderite** (Gr. σφαῖρα, *a globe*; and σίδηρος, *iron*). A name given by Hausmann to a spheroidal and radiated variety of Sparry Iron-ore found in Greenstone, at Hanau in Western Germany; and in the circle of Jaslo in Austrian Galicia.

The name is also applied generally to the globular concretions of spathose carbonate of iron found in some amygdaloids or lavas. [SPARRY IRON-ORE.]

Sphaerulite or **Spherulite.** A term applied by some mineralogists to a variety of Obsidian or Pearlstone, which occurs in small rounded grains. [PEARLSTONE.]

Sphene (Gr. σφήν, *a wedge*, from the shape of the crystals). A titanate and silicate of lime (or a silicate of titanium, in which part of the latter is replaced by lime). It is found crystallised and sometimes in granular or foliated masses of a brown, grey, and yellow colour, near Tavistock and Tremadoc; in the Shetlands; at Cariglinneen, co. Down; and at Crow Hill near Newry.

Sphenoid Bone (Gr. σφηνοειδής, from σφήν). One of the bones of the head; so called from its being wedged in, as it were, amongst the other bones. It is of a most irregular shape, and very complicated in its processes and connections with the other bones. When removed, it is something of the figure of a bat with its wings extended. It is connected with all the bones of the skull, and with those of the palate, cheeks, and upper jaw. Homologically, the sphenoid of anthropotomy answers to seven bones, the basisphenoid, alisphenoids, orbitosphenoids, and pterygoids.

Sphere (Gr. σφαῖρα, *a ball*). In Astronomy, the concave expanse of the heavens, which, having no definite limit, appears to the eye as the interior surface of a sphere enclosing the earth, which is placed at the centre. The ancients gave the name of *sphere* to the orbits of the several heavenly bodies; thus, the sphere of Jupiter, the sphere of Saturn, the sphere of the fixed stars. In the Ptolemaic astronomy, the different spheres were supposed to be solid and transparent, moving about their common centre independently of each other, and each carrying its appropriate body along with it. [PTOLEMAIC SYSTEM.]

SPHERE. In Geometry, a solid body described by the revolution of a semicircle about its diameter; or it may be defined to be a body bounded by a surface of which every point is equally distant from a single point within the surface, called the *centre of a sphere*. If r denote the radius of the sphere, and x, y, z rectangular co-ordinates, the origin being at

the centre, the equation of the surface is $x^2+y^2+z^2=r^2$.

The following are some of the principal metrical properties of the sphere (for other descriptive properties, see SPHERICS): 1. The surface of the sphere is equal to four times the area of one of its *great circles*; i.e. of a section made by a plane passing through its centre. 2. The curve surface of any zone, or portion contained between two parallel planes, is equal to the curve surface of a cylinder of the same height with the height of the zone, or the distance between the planes, and of the same diameter with the sphere. Hence it follows that the whole surface of the sphere is equal to the curve surface of the circumscribing cylinder. 3. The volume of a sphere is equal to that of a pyramid whose altitude is the radius, and whose base is equal to the surface of the sphere; and hence the volume of the sphere is one-third of the product of its radius into its surface. 4. The sphere is equal to two-thirds of its circumscribing cylinder.

Let r denote the radius of the sphere, s its superficies, v its volume, and π the ratio of the semicircumference to the radius $= 3{\cdot}14159$; then since the area of a circle of which r is the radius is πr^2, the properties above stated give the relations which follow; viz.

$$s = 4\ \pi\ r^2 = 12{\cdot}56637\ \times\ r^2,$$
$$v = \tfrac{1}{3}\ r\ s = \tfrac{4}{3}\pi\ r^3 = 4{\cdot}18859 \times r^3.$$

Spherical Curvature. [CURVATURE, SPHERICAL.]

Spherical Excess. The excess, above two right angles, of the sum of the angles of a spherical triangle. [EXCESS, SPHERICAL.] If Δ denote the superficial area of the triangle whose excess estimated in circular measure is E, we have the simple relation $\Delta = \mathrm{E}\,r^2$, where r is the radius of the sphere. [SPHERICS.] According to Legendre's Theorem, if the radius of the sphere be very large when compared with the arcs of the spherical triangle, then each angle of the latter exceeds by one-third of the spherical excess the corresponding angle of the *plane triangle* whose sides are equal in length to the arcs of the spherical triangle. The area of this plane triangle being approximately the same as that of the spherical one, an approximate value of the spherical excess is readily obtained in geodetical measurements. With respect to the latter subject, however, we cannot here enter into details, and must refer the reader to published accounts of the British Ordnance Survey. In connection with the spherical excess there are two formulæ which, for the sake of reference, may here find a place. The first is known as Cagnoli's, the second as Lehuillier's Theorem.

$$\mathrm{Sin}^2\frac{\mathrm{E}}{2} = \frac{\sin s\,.\,\sin(s-a)\sin(s-b)\sin(s-c)}{\cos^2\frac{a}{2}\ \cos^2\frac{b}{2}\ \cos^2\frac{c}{2}}$$

$$\tan^2\frac{\mathrm{E}}{4} = \tan\frac{s}{2}\tan\frac{s-a}{2}\tan\frac{s-b}{2}\tan\frac{s-c}{2}.$$

As usual, a, b, and c here denote the sides of the spherical triangle, i.e. the angles which the arcs subtend at the centre of the sphere, and s denotes half their sum.

Spherical Indicatrix. [INDICATRIX, SPHERICAL.]

Spherics. In Geometry, the doctrine of the properties of a sphere considered as a geometrical surface. The section of a sphere by any plane is a circle which receives the name of *great circle* or *small circle*, as its plane passes or does not pass through the centre of the sphere. The diameter of the sphere which is perpendicular to a great circle is called the *axis* of the latter, as well as of all the *parallel* small circles; the extremities of this axis are the *poles* of the series of circles, and any great circle through these poles is called a *secondary circle*; the latter cuts the original or *primary* great circle and all its parallels at right angles. The angle between any two secondaries (sometimes called a *spherical angle*, though there appears to be no necessity for the distinction) is measured by the arc which they intercept upon the primary. The poles of these secondaries lie on the primary, and the inclination of the former circles may also be measured by the arc of the latter circle between two of their poles.

The shortest line on the sphere by which two given points can be joined is the arc of the great circle which passes through those points, and is less than a semicircle. Three points on the sphere form a *spherical triangle* whose sides are the shortest lines (great circles) which join the points; these sides are proportional to the angles which they subtend at the sphere's centre. The three poles of the sides of a spherical triangle which lie in the same hemisphere as the triangle itself, form the *polar triangle*. The latter and the original are also called *supplemental triangles*, since a side of the one is the supplement of the corresponding angle of the other. Spherical triangles have many properties in common with plane triangles; for instance, the greater angle always subtends the greater side, and if two angles are equal, so are the opposite sides, and the triangle is *isosceles*. The angles of a spherical triangle, however, are together *greater* than two right angles; the *excess* is a measure of the superficial area of the triangle. A right-angled spherical triangle is one which has a right angle; the supplemental triangle in this case has one of its sides equal to a quadrant, and is termed *quadrantal*. There are also bi-rectangular and bi-quadrantal triangles, as also *tri-quadrantal* ones, the sides of which are all quadrants and the angles all right angles. The spherical surface enclosed between two great semicircles is called a *lune*; its area clearly bears the same ratio to that of the whole sphere which the *angle of the lune* bears to four right angles. From this is deduced the important theorem that the *surface of a spherical triangle has to that of the hemisphere the same ratio which the spherical excess has to four right angles.* For

further properties of the sphere, see SPHERE and TRIGONOMETRY.

Sphero-conic. The section of a sphere by a quadric cone having its vertex at the centre. Such a section obviously consists of two closed and perfectly symmetrical curves in the opposite hemispheres determined by one of the principal planes of the cone. Either of these closed curves may be regarded as a *spherical ellipse*. The same sphero-conic, however, may be regarded as a *spherical hyperbola* in either of the hemispheres into which the sphere is divided by one of the principal planes which cut the cone. The cyclic planes of the cone cut the sphere in the *cyclic arcs of the sphero-conic*, which latter are the analogues of the asymptotes of a plane conic. The focal lines of the cone determine on the sphere the *foci of the sphero-conic*. The great circles of which the several points of a sphero-conic are the poles, envelope the *reciprocal sphero-conic*; of which latter the foci and cyclic arcs are respectively the poles and polars of the cyclic arcs and foci of the original sphero-conic.

The properties of sphero-conics are in many respects precisely similar to those of plane conics. For instance, the sum (or difference) of the arcs (of great circles) joining the foci to any point of a sphero-conic is constant, and the two tangents from any point to a sphero-conic are equally inclined to the arcs which join that point to the two foci. The reciprocals of these theorems show that every tangent to a sphero-conic forms with the cyclic arcs a triangle of constant area, and that the segments are equal which a sphero-conic and its cyclic arcs intercept upon any secant. An elaborate memoir on sphero-conics, by Chasles, will be found in the *Trans. of the Royal Acad. of Brussels*, vol. vi.; it was translated (with additions) by Dr. Graves of Dublin, and published in 1837. A résumé of this memoir, but with original demonstrations, is given by Dr. Salmon in his *An. Geom. of Three Dimensions*.

Sphero-polar Reciprocal. [POLAR RECIPROCAL.]

Spherograph. An instrument invented for the practical application of spherics to navigation. By its aid any possible spherical triangle can be constructed without dividers or scales.

Spheroid (Gr. σφαιροειδής). In Geometry, a solid generated by the revolution of an ellipse about one of its axes. If the generating ellipse revolves about its major axis, the spheroid is *prolate*, or oblong; if about its minor axis, the spheroid is *oblate*.

Let $2a$ be the axis of revolution, and $2b$ the diameter of the generating ellipse perpendicular to the axis; then the origin of the co-ordinates being at the centre, and x being taken on the semi-axis a, the equation of the surface of the spheroid is

$$\frac{x^2}{a^2} + \frac{y^2 + z^2}{b^2} = 1.$$

Let k^2 denote the ratio of the difference of the squares of a and b to the square of a; i.e. make $a^2 k^2 = a^2 - b^2$, and put $\pi = 3{\cdot}14159$: then the whole surface S of the spheroid is expressed by the following series, in which the upper signs are to be used if the spheroid is oblong (i.e. if a is greater than b), and the under signs if the spheroid is oblate: viz.

$$S = ab\left(1 \mp \frac{1}{2.3}k - \frac{1}{2.4.5}k^2 \right.$$
$$\left. \pm \frac{3}{2.4.6.7}k^3 - \&c.\right)$$

The volume of the spheroid, expressed by $\frac{4}{3}\pi a b^2$, is two-thirds of that of the circumscribing cylinder.

An oblate spheroid being approximately the figure of the earth, its properties are of great importance. Referring the reader desirous of full information on the subject to Airy's article in the *Ency. Metrop.* or to the published account of the Ordnance Survey, we will here merely add three formulæ, relative to the curvature of the earth, which are sometimes useful.

Let a be half the polar axis, b the radius of the equator, e the ellipticity, or a number such that $b = a\ (1 + e)$ [ELLIPTICITY], and l the given latitude. Also, let r be the radius of curvature in the direction of the meridian, r' the radius of curvature in the direction perpendicular to the meridian, and R the radius of curvature of a normal section, making with the meridian an angle $= \theta$; then

$$r = a\,(1 - e + 3\,e \sin^2 l) \quad . \; . \; . \; (1)$$

$$r' = a\,(1 + e + e \sin^2 l) \quad . \; . \; . \; . \; (2)$$

$$R = \frac{r\,r'}{r \sin^2\theta + r' \cos^2\theta} \quad . \; . \; . \; . \; (3)$$

Spheroidal Condition of Liquids. When a few drops of a liquid are allowed to fall on a highly heated smooth surface, they are not at once converted into vapour, but, rebounding, roll over the hot surface without moistening it, in the shape of flattened spheroids. This, at first sight, extraordinary and anomalous phenomenon has been called the spheroidal condition of a liquid. After the temperature of the heated body has sunk below 300° Fahr., in the case of water the liquid will no longer remain in the spheroidal state, but boils and disappears in the ordinary way. This phenomenon was first described by Eller at the Academy of Berlin in 1746; ten years later it was studied by Leidenfrost, by whose name it is frequently called; since then many other experiments have been made upon it, but most of our knowledge of this curious property of liquids was derived about twenty years ago from the investigations of M. Boutigny, who first gave to it the name by which it is now known. When in the spheroidal condition, the liquid is not in contact with the hot surface, but is lifted up and sustained by the vapour which is rapidly generated from that portion of the drop nearest the heated body. From this cause, if a dish

perforated with fine holes be used, the liquid will not run through so long as it remains in the spheroidal state. M. Boutigny and others believe that the space, which can easily be seen to exist, between the liquid and the hot plate, is due to the repulsive force of heat; but it is probable that this repulsion would not be exercised at sensible distances. Moreover, in order to assume the spheroidal state it is necessary that the substance be volatile, and if this be the case solids as well as liquids can become spheroidal. The cause of the phenomenon is, therefore, to be found mainly in the developement of vapour from the under surface of the spheroid: cushioned on this vapour, it is moulded by the resultant action of gravity and cohesion.

The best way to obtain the spheroidal state is to heat a little metal dish or spoon to redness, and then to pour in a little water; no ebullition occurs, but the water skips about in little globules or gathers into a mass with a beautifully crimped border; it is evidently out of contact with the vessel, and from the bad conducting power of the vapour only slowly evaporates, unless, however, the heat be withdrawn, and then it instantly flashes into steam. The temperature of the spheroid is a little below the boiling point of the liquid; with water it is about 206° Fahr.

The passage of a large body of water from the spheroidal into the ordinary condition, and the consequent sudden copious generation of steam, has been assigned as a probable cause of the explosion of over-heated steam boilers. A red-hot dish thrown on water is lifted out of contact with the latter, until it has cooled down so far that the tension of the vapour generated is insufficient to sustain the dish. By roughening the surface, or, better, coating it with certain oxides, the conversion of a liquid into the spheroidal state may partially or wholly be prevented. Owing to the separation from the hot surface, due to the spheroidal condition, water or even mercury may be frozen in a red-hot crucible by a bath of solid carbonic acid and ether. From the same cause laundresses know when their irons are hot enough, by the saliva rolling off them, or their wetted finger being unburnt when the iron is touched.

It is owing to the protective influence of the vapour shell surrounding a liquid in the spheroidal state, that a moistened hand can be plunged into molten lead or iron with perfect impunity. Some of the escapes from the fiery ordeal may thus be explained. To repeat the experiment, the molten lead should be as hot as possible, and the finger or hand should be dipped in liquid ammonia before it is plunged in the red-hot mass.

Spherometer (Gr. σφαῖρα, and μέτρον, *measure*). In Physics, an instrument for measuring with great precision the thickness of small bodies, the curvature of optical glasses, &c.

Spherosiderite. A variety of spathose iron-ore. [SPHÆROSIDERITE.]

Spherulite. A variety of Pearlstone. [SPHÆRULITE.]

Sphex (Gr. σφήξ, *a wasp*). A generic name restricted to those burrowing wasps which live in single pairs, and have the wings always outstretched. The female usually places by the side of the eggs she has laid the bodies of insects, killed or paralysed, to serve as food for the grub when hatched.

Sphigmometer (Gr. σφιγμός, *a binding tight*). An instrument for counting the arterial pulsations.

Sphincter (Gr. σφιγκτήρ, from σφίγγω, *I bind tight*). A term applied by anatomists to several muscles which close or contract the orifices which they surround.

Sphinx. In Entomology, the generic name of the Hawk-moths, so called from their size and power of flight. The death's-head moth (*Acherontia atropos*), the privet moth (*Sphinx ligustri*), the humming-bird moth (*Macroglossa stellatarum*), are indigenous examples of the genus, now raised, as the names quoted imply, to the rank of a family (*Sphingidæ*) including many other modern generic sections. The attitude of the caterpillar of the hawk-moths, resembling that of the fabulous sphinx of Egyptian sculpture, suggested to Linnæus the generic name.

SPHINX. The name and figure of this mythical being have been commonly regarded as originating in Egypt; and there is no doubt that the impression made by the art and the theology of that ancient kingdom on the minds of the Greeks, led them in course of time to trace to Egyptian soil the growth of Hellenic art and science. Thus, the sight of the colossal figures at Sais, which Herodotus (ii. 175) terms Ἀνδρόσφιγγες, or male sphinxes, led him probably to the conclusion that the Greek Sphinx was simply borrowed from that of Egypt. He was not less mistaken in this supposition than on the other points of ethnology and mythology in which he was led astray by the impudent assumptions and falsehoods of Egyptian priests. The word *sphinx* is genuinely Greek, being connected with σφίγγω, *to bind fast*; and thus the Sphinx is preeminently the *throttler*, and answers precisely to the Sanscrit ahi, *the snake*, from the root *anh*, to press together or choke, which reappears in the Greek ECHIDNA, and the Latin anguis. This snake or serpent is the Hindu monster VRITRA, who is engaged in deadly strife with Indra, and who, like the Sphinx, brings drought upon the earth, until he is smitten by the spear of the sun-god, as the Theban Sphinx is smitten by ŒDIPUS. This battle, which in India and Greece is wholly or almost wholly physical, assumed on Iranian ground a moral aspect, and became the internecine struggle between AHRIMAN and ORMUZD [DUALISM], the strife between spiritual good and evil. In Western mythology, the same conflict is set forth in the battle of Apollo with PYTHON, of SIGURDR with Fafnir, of Perseus with the Libyan dragon, of Bellerophon with the CHI-

MÆRA. These legends show, further, that the idea of the Sphinx is not more Egyptian than the word. The Sphinx, like Echidna, has the head of a woman with the body of a beast, and shares with Typhon the claws of the lion, the wings of a bird, and the serpent's tail. In short, the resemblance of the Hellenic Sphinx to the so-called Sphinx of Egypt is at best very distant; and the name is found in Greek mythology at a period long preceding that in which Egypt was opened to Greek merchants or travellers. In the Hesiodic *Theogony*, the Sphinx is a daughter of ORTHROS and Chimæra, and a granddaughter of Typhon and Echidna; and the form Phix, which the name assumes in this poem, serves only to indicate the connection of the Greek σφίγγω with the Latin *figo*, and thus to bring before us the same idea which is presented in the Sanscrit Ahi and Vritra. The derivation of the name Phix from the Bœotian Mount Phikion must be classed with the derivations of Apollo Lykios from the country Lycia, or of ORTYGIA, as an epithet of Artemis, from an islet off the eastern coast of Sicily.

Thus, then, like Vritra, the Sphinx is a monster who chokes up the rain-clouds and prevents them from refreshing the earth in the time of drought, and, like Vritra, she can be overcome only by the power of the sun, signified in the Theban legend by Œdipus. A few mythical phrases serve to explain the tale. The first, *Œdipus is the slayer of the Sphinx*, reproduces the struggle of Zeus against Typhon, of Apollo with the Delphian dragon; the second, *Œdipus has smitten the Sphinx*, as it sits like the storm-cloud on the brow of the hill overhanging the city, brings before us the spear of Indra when it falls on Vritra, the demon who lurks behind the masses of thunderclouds piled above the plain. In the riddle of the Sphinx we have the old saying that man cannot comprehend the language of the thunder; while in the solution of the enigma by Œdipus, we see the wisdom of Apollo which even HERMES longs in vain to acquire, and which knows the secret things of the highest heavens and the unfathomable sea. The discovery of the secret is followed by the death of the Sphinx, who precipitates herself from the cliff on which she has been seated, precisely as the smiting of Vritra is followed by torrents of rain from the clouds which he had made his hiding-place.

The form of the so-called Egyptian Sphinx is that of a winged lion with a human head and bust, always in a lying attitude, whereas the Greek Sphinx is represented in any attitude which might suit the fancy of the poet. The Egyptian figures seem to have been set up in avenues, forming approaches to the great temples. The statue disinterred by Belzoni near the Pyramids of Ghizeh has again been nearly covered with sand. It is stated by Pliny that the Sphinx represented the Nile in a state of flood, as this event occurred regularly under the signs of the Virgin and the Lion. Figures of lions have also been found with the heads of rams and hawks. The Egyptian Sphinx had no wings, and thus presents another point of difference to the monster of Aryan mythology.

Sphragistics (Gr. σφραγιστικός, from σφραγίς, *a seal*). The science of seals, their history, peculiarities, and distinctions, especially with a view to the means which they afford of ascertaining the age and genuineness of documents to which they are affixed. Ancient seals were chiefly impressed on common wax of different colours; sealing-wax came into use in the sixteenth century. This branch of diplomatics owes its origin to Heineccius, who published a work on the subject in 1709. Gercken's treatise, styled *Anmerkungen über die Siegel zum Nutzen der Diplomatik* (Augsburg 1781), will be found a useful guide.

Spiauterite. [WURTZITE.]

Spiccato (Ital. *divided*). In Music, a term indicating that every note is to have its distinct sound. When used in relation to instruments played with a bow, it is to be understood that every note is to have a bow distinct from the preceding or succeeding one.

Spices. The generic term for those aromatic or fragrant vegetable productions, pungent to the taste, which are used as flavouring ingredients in sauces and cookery. They also serve as condiments. The principal of these in common use are nutmegs, mace, allspice or pimento, ginger, cinnamon, and cloves.

Spider. [ARACHNIDÆ.]

Spike (Lat. spica, *an ear of corn*). In Botany, a form of inflorescence in which all the flowers are sessile along a common axis, as in *Plantago*.

Spikenard. The spikenard of the ancients has been, with tolerable certainty, pronounced by Dr. Royle to be the plant called *Nardostachys Jatamansi*, the root of which is highly esteemed at the present day throughout the East as a perfume and as a stimulant medicine. The plant is a native of the mountainous parts of the north of India. Some, however, refer the Spikenard to one of the fragrant Indian grasses belonging to the genus *Andropogon*, the *A. Iwaranensa* of Roxburgh.

Spiking Guns. Rendering guns unserviceable either (1) temporarily, by pushing into the vent a spring spike which can be removed when the spring is compressed by a rammer pushed down the bore from the muzzle; or (2) more permanently, by driving an iron nail hard into the vent, which must be drilled out before the gun can be used.

Spilanthes (Gr. σπίλος, *a spot*, and ἄνθος, *a flower*). A large genus of composite tropical weeds, the leaves of many of which have a singularly pungent taste, which is especially noticeable in the Pará Cress, *S. oleracea*. This plant is cultivated as a salad and potherb in tropical countries, and, like many cultivated plants, its native country is uncertain. The Japanese call the plant Hoko So.

Spinach (Ital. spinacce, from Lat. spina, *a thorn*). A well-known potherb, the *Spinacia oleracea* of botanists. The common Spinach is a

hardy annual, whose native country is unknown, though generally supposed to be Western Asia. It has been cultivated in this country for more than 300 years, and is noticed in Turner's *Herbal* of 1568 as 'an herb lately found and not much in use.' The plant has large thick succulent deep-green leaves, for the sake of which alone it is cultivated, and which are considered wholesome; when properly dressed, and thoroughly deprived of all moisture before being mashed with butter or rich gravy, they make an excellent dish, which may be eaten with any kind of meat. The seeds of one of the species are spiny, whence it is commonly called, tautologically, Prickly Spinach. It is a singular fact that the water drained from Spinach after being boiled is capable of making as good match-paper as that made by a solution of nitre.

Spinal Chord or **Spinal Marrow.** The name given in Anthropotomy to the portion of the great axis of the nervous system lodged in the vertebral column. It was originally suggested by the analogy of the part in texture, colour, and position in the neural canal, to the marrow in the long bone of the limbs. [MYELON.]

Spindle (A.-Sax. spindel). In Geometry, a solid generated by the revolution of the arc of a curve line about its chord. The solid generated by the revolution of a curve about its axis is called a *conoid*.

In Mechanics, the term *spindle* sometimes denotes the axis of a wheel or roller.

SPINDLE. [WEAVING.]

Spindle-tree. The common name for *Euonymus europæus*.

Spine. [VERTEBRÆ.]

Spines (Lat. spinæ). Branches which, being imperfectly formed, lose their power of extension, become unusually hard, and acquire a sharp point. They are very different from aculei, or prickles, which are a kind of hardened hairs. In leaves, they are processes formed either by an elongation of the woody tissue of the veins, or by a contraction of the parenchyma; in the former case, they project beyond the surface or margin of the leaf, as in the holly; in the latter case, they are the veins themselves become indurated, as in the palmated spines of *Berberis vulgaris*.

Spinel (Fr. spinelle). An anhydrous aluminate of magnesia, consisting (when pure) of 71·99 per cent. of alumina and 28·01 magnesia; but part of the magnesia is often replaced by lime and the protoxides of zinc, manganese, and iron, and the alumina sometimes by peroxide of iron.

It is of various tints of red, violet, and yellow, sometimes black, as at the copper mine, Migiandone, in the valley of Toce in Piedmont; occasionally nearly white. It occurs in octahedrons, the edges of which are occasionally replaced, and sometimes in rhombic dodecahedrons; also in macles. It is found in Wicklow in small rounded grains, in the sands of mountain streams; but the finest specimens are brought from Ceylon, Siam, Pegu, and other eastern countries. Spinel constitutes a beautiful gem, which is often sold for Oriental Ruby. The Scarlet Spinel is called *Spinel Ruby* by lapidaries; the rose-red, *Balass Ruby*; the yellow or orange-red, *Rubicelle*; the violet-coloured, *Almandine Ruby*.

Spinellane or **Spinelline.** A name given to the variety of Sphene (*Séméline*) found at Lake Laach, near Andernach, on the Rhine.

Spinelle. [SPINEL.]

Spinelle Ruby. The name given by lapidaries to the scarlet varieties of Spinel.

Spinet (Ital. spinetta). A musical stringed instrument with a key-board, &c., similar in construction to a harpsichord, from which, indeed, it little differs, except in being much smaller; but like that, it is now superseded by the pianoforte.

Spinners or **Spinnerets.** In Entomology, organs with which insects form their silk or webs. In spiders they consist of two retractile pieces issuing from anal protuberances, and giving out the threads.

Spinning. [COTTON MANUFACTURE.]

Spinning Jenny. [COTTON MANUFACTURE.]

Spinozism. This name is sometimes used to denote the ethical system of Benedict Spinoza, a Jew of Amsterdam, born in 1634. This system was called ethical, because, although founded on a speculative view of nature, it had freedom and duty for its object. From a few axioms he deduced mathematically the principle that 'there can be no substance but God: whatever is, is in God, and nothing can be conceived without God.' His system has been pronounced immoral, in so far as it 'prostrates the energies of the soul before a cold and sterile synthesis of the All, considered as a mere mechanism of causation.' This system is closely connected with the critical method by which, in the *Tractatus Theologico-Politicus*, he examined the several books of the Old Testament for the purpose of showing that any theory of biblical infallibility was untenable, and of protesting against the position which 'submitted the divine light of reason, heaven's best and noblest gift, to the dead letter of a book exposed during so many ages to all the hazards of malice, mutilation, and neglect.' With this purpose he entered into a detailed examination of the several books, the circumstances of the writers, and the occasion of their composition, and thus sought to show that all the documents illustrated the psychological conditions of their literary origin, like any other human records. He thus separated religion from theology, making the former to consist in a spirit which harmonised with this scientific method, and was prepared to accept all conclusions established as facts, without regard to consequences. This distinction led him to claim the right of free enquiry only for the religion of philosophy as distinguished from the religion based on traditionary theology. (Hallam's *Literary History*; Brucker, *History of Philo-*

sophy; Mackay, *The Tübingen School and its Antecedents*.)

Spinster. Literally, a woman who spins; but in Law the word is the common title of unmarried women.

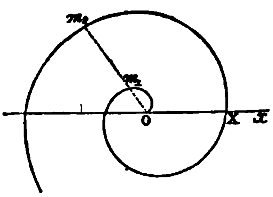
Spinthère (Gr. σπινθήρ, *a spark*). A greenish variety of Sphene, occurring crystallised in very irregular four-sided pyramids, which are obliquely truncated, in Dauphiny, adhering to crystals of Calc Spar.

Spiracles (Lat. spiraculum, *a breathing hole*). In Entomology, the breathing pores of insects are so called.

Spiræa (Lat.; Gr. σπειραία). A genus of Rosaceous plants, consisting of shrubs or perennial herbs. Among the latter is the fragrant-blossomed Meadow Sweet, *S. Ulmaria*. The essential oil of this plant has been produced artificially by the oxidisement of salicine, and has been termed *spiroylous acid*. Its chemical formula is $C_{14}H_5O_3 + HO$.

Spiral. In Geometry, the name given to a large class of curves which, in general, have the property of circulating round a point or *pole*. They receive different names according to their properties or their discoverers. Some of the principal spirals are noticed under the titles, SPIRAL OF ARCHIMEDES, HYPERBOLIC SPIRAL, LOGARITHMIC SPIRAL, PARABOLIC SPIRAL, &c. For the investigation of the properties of spirals, see Leslie's *Geometrical Analysis*; Peacock's *Examples of the Differential and Integral Calculus*; Maclaurin's *Fluxions*, &c.

Spiral of Archimedes. The curve traced by a point moving with uniform velocity along a line (radius vector) which rotates with uniform velocity around a point. Its equation is obviously $r = a\theta$; it starts at the pole o, and every two consecutive convolutions intercept a constant length $2\pi a = m_1 m_2$ upon all radii vectores. It is sometimes called the *equable spiral*, and was proposed by Conon to Archimedes, who in his treatise *On Spirals* investigates many of its properties. It is the pedal of the involute of the circle, and has for its inverse the hyperbolic spiral $r = \frac{a}{\theta}$, or reciprocal of the involute. [PEDAL.] These spirals belong to the family whose general equation is $r = a\,\theta^n$, a characteristic property of which is that the radius vector as it rotates is cut less and less obliquely by the curve; it is only after an infinite number of rotations, however, that the radius vector cuts the curve perpendicularly.



Spiral Vessels. In Vegetable Anatomy, spiral vessels are membranous tubes with conical extremities, lined in the inside by a fibre twisted spirally, and capable of unrolling with elasticity. Their function is that of the conveyance of air. They are found in almost any part of the plant except the bark; but are most abundant in leaves and flowers, and least common in the stem and root, except in the medullary sheath of the former.

Spire (Lat. spira). In Architecture, amongst the ancients, the base of a column, also the astragal or torus of the base. In modern architecture, however, the term is applied to the erection above the tower of a church, which diminishes gradually as it rises, sometimes assuming the form of a plain slender pyramid, polygonal on plan, rising from the square base formed by the tower from which it springs.

Spirifer. The name of a genus of extinct Palliobranchiate molluscs, characterised by the shell having two internal calcareous spiral appendages.

Spirit. [SOUL.]

Spirit Level. A glass tube nearly filled with spirit of wine, and hermetically sealed at both ends. The exact horizontal position of its axis is ascertained by the air bubble being at equal distances from the middle point in the length of the tube. The level is used for determining the relative heights of ground at two or more stations, and also for determining the horizontal position of any surface.

Spirit Room. A department in the hold of a ship, which serves as the vessel's wine-cellar. Its precise locality depends on the circumstances of stowage.

Spirit of Wine. [ALCOHOL; FERMENTATION.]

Spirits. Fluids containing more than half their bulk of absolute alcohol are known by this name—that in which equal parts of water and alcohol are combined being known as *proof* spirits; and the increased proportion of the latter ingredient being designated as so many degrees over proof. The word is also employed for wood alcohol, the common naphtha; and in the language of certain trades, as, for instance, the dyers, certain chemical compounds, as chloride of tin, are also called *spirits*.

Generally, however, spirits are understood to signify such alcoholic drinks as are intended for drinking. Of these there are three principal kinds: brandy, which is distilled from wine; rum, from fermented molasses; whisky and gin or geneva, from malted grain. Large quantities of spirits are distilled from potatoes, the starch of which is fermented. The flavours of spirits are derived from certain essential oils or ethers developed in the process of distillation, or gradually evolved as the spirit is kept, or, in the case of grain spirits, added as flavouring to the distilled fluid.

As the intrinsic price of spirits, owing to the heavy customs and excise duties which are levied on them, is far less than the selling price, spirits are stored in bond, even when manufactured at home, the duty being payable only when the fluids are taken out in parcels for consumption.

The following are the prices of proof spirits (in bond) by the gallon, for four years:—

	1861	1862	1863	1864
	s. d.	s. d.	s. d.	s. d.
Rum, West Indian	2 6$\frac{3}{8}$	2 2	1 11$\frac{3}{4}$	2 3$\frac{1}{4}$
Brandy	9 1	9 1	7 6$\frac{1}{4}$	6 2$\frac{5}{8}$

The excise duty paid on British spirits for the five years ending with 1865, amounts, on an average, to 9,500,000*l.* per annum.

Imports of Foreign Spirits for the Five Years ending 1865.

	1861	1862	1863	1864	1865
	gallons	gallons	gallons	gallons	gallons
Rum	8,114,823	7,765,099	7,194,738	5,499,872	6,898,599
Brandy	2,097,934	2,375,835	3,132,293	4,907,771	3,122,576
Other foreign and colonial spirits .	666,245	417,481	858,999	1,328,802	1,700,407
Total	10,879,002	10,558,415	11,186,030	11,736,445	11,729,582

The importations show little aggregate variation, the increase of foreign spirits being due to the equalisation of duties.

Spirit-rapping. [CLAIRVOYANCE.]

Spirito, Spiritoso (Ital. *spirit, with spirit*). In Music, denotes, when affixed to a movement, that is to be performed in a spirited manner.

Spiritualism. That system according to which all that is real is spirit, soul, or self; that which is called the external world being regarded as either a succession of notions impressed on the mind by the Deity, or else the mere educt of the mind itself. The first is the spiritualism of Berkeley; the second, which may be called pure egoism, is that of Fichte. [MATERIALISM.]

Spiritus Asper (Lat.). In Grammar, the rough breathing, marked thus ʽ, placed before Greek words beginning with a vowel, which should be pronounced like words beginning with *h* in English. It is also placed before all words beginning with the letter ρ.

Spiritus Lenis (Lat.). In Grammar, the soft breathing, marked thus ʼ, placed before all Greek words beginning with a vowel, which have not the rough breathing. It thus denotes merely the absence of the spiritus asper.

Spirketting. That part of the inner planking of a ship which lies between the ports and the next lower water-way. It serves to keep the water-way fixed, which, in its turn, holding down the beam ends, gives solidity to the entire structure.

Spirous Acid. [SALICYLOUS ACID.]

Spirulidæ. The name of a family of Dibranchiate Cephalopods, of which the genus *Spirula* is the type. They are characterised chiefly by having a spiral discoid chambered shell developed in the substance of the mantle, instead of a calcareous or horny plate.

Spittle. [SALIVA.]

Spiza (Gr.). The Spiza of Aristotle is supposed to be the same as the Chaffinch, or *Fringilla cœlebs*, of Linnæus. The chaffinch is permanent in the South of Europe, and a regular bird of passage in the northern countries. Its notes are susceptible of a greater range of modulation than in the other members of the genus. The colours of the male are far more brilliant than those of the female.

Splanchnology (Gr. σπλάγχνον, *an entrail*, and λόγος). The doctrine of the viscera.

Splanchnoskeleton (Gr. σπλάγχνον, and σκελετόν, sc. σῶμα, *a dried body* or *skeleton*). Those bones which are connected with the sense organs and viscera, e. g. the heart-bone in the bullock and some other large quadrupeds.

Splayed (a corruption of *displayed*). In Architecture, a term used to express an angle cut off, or oblique on plan.

Spleen (Gr. σπλήν). A spongy viscus, of an oval form, the use of which is unknown. In the human subject it is placed in the left hypochondrium, between the eleventh and twelfth false ribs. The term *spleen* is also used for a species of hypochondriasis to which the English are said to be particularly open.

Splenitis (Gr.). Inflammation of the spleen.

Splenius. A flat muscle, situated between the back of the ear and the lower and posterior part of the neck.

Splent or Splint Coal. A hard laminated kind of coal, less bituminous than caking coal, and intermediate between Cannel and common pit-coal. It burns free and open, without caking, and furnishes a good house-coal. Splint coal is produced by the Glasgow coal-field, as well as by those of Shropshire, Warwickshire, Derbyshire, and Nottinghamshire, and constitutes the bulk of the coal from North and South Staffordshire.

Splicing (Ger. splessen, *to split*). Joining the two ends of a rope, or uniting one end to any intermediate part by interweaving the strands. An *eye splice* forms an eye or circle at the end of a rope. A *short splice* is the joining of two ends not intended to pass through a block. A *long splice* is used to unite two ends which have to pass through a block. It is formed by untwisting the two ends, and interweaving the strands of one in the alternate strands of the other. The strands must be hauled well through, and beaten with a marline spike to render them firm.

In Naval language, the phrase, *to splice*

the main brace, denotes an extra allowance of spirits in cases of cold or wet.

Splint (connected, like *splinter*, with *split*). A piece of wood or pasteboard, so shaped as to support a broken or debilitated limb.

Splintery. That fracture of minerals which is nearly even, but exhibits small splinters or scales thicker at one extremity than the other, and adhering by their thicker ends to the broken surface.

Spodumene (Gr. σποδόω, *to burn to ashes*). A silicate of alumina and lithia, with part of the lithia replaced by soda. It is found in crystallised and laminated masses, hard, brittle, translucent, and of various shades of green or grey. It was first discovered at Utö, in Sweden. Before the blowpipe, it exfoliates into little scales of an ash colour; hence its name. It is also found in granite, at Killiney, co. Dublin, in long bent prisms of a greenish-grey colour. It is also called *Triphane*.

Spoliation, Writ of. In English Law, this writ is obtained in the ecclesiastical courts for the fruits of a benefice. The suit founded on this writ lies for one incumbent against another, where they both claim by one patron, and the right of patronage is not in question.

Spondee (Gr. σπονδή, *a libation*). In Greek and Latin Poetry, the name of a foot consisting of two long syllables. It was so called because, from its slow movement, it was ordinarily employed in the hymns sung in honour of the gods during the offering up of a sacrifice.

Spondaic verse is an hexameter line, in which the two last feet are spondees, instead of the usual termination, a dactyl and a spondee; but in these the fourth foot is always dactylic.

Spondias (Gr. *a kind of wild plum*). A genus of *Anacardiaceæ*, the species of which are natives of the tropics of both hemispheres. The fruits of some of them are edible. Thus, in Brazil and the West Indies, *S. lutea*, *S. Mombin*, *S. tuberosa*, &c., yield fruits eaten under the name of *Hog Plum*, the taste of which is said to be peculiar, and not agreeable to persons unused to them. These fruits are chiefly used to fatten swine. *S. dulcis*, a native of the Society Isles, yields a fruit compared in flavour to that of the Pine-apple. *S. mangifera* yields a yellowish-green fruit, which is eaten in India, and is used as a pickle in the unripe state.

Some of the species are employed medicinally. Thus, the bark, leaves, and wood of *S. mangifera* are used in various complaints in India. An insipid gum also exudes from the bark of this tree. *S. Mombin* has astringent leaves, while its fruits are laxative, and its seeds are said to be poisonous. The bark of *S. venulosa* has aromatic astringent properties. *S. tuberosa* is also employed in fevers; the fruit is the part used. *S. Birrea* affords to the natives of Abyssinia an edible kernel, while its fruits are employed in Senegal in the preparation of an alcoholic drink.

Spondylus (Lat. from Gr. σπόνδυλος, or σφόνδυλος). The name of a Linnæan genus of the Vermes Testacea, comprehending the spring oysters; characterised by having a strong tooth on each side of the depression lodging the elastic ligament of the hinge of the shell. The genus is included in the Ostracean family of the Acephalous Testacea by Cuvier, and has been subdivided by Lamarck into the genera *Spondylus* proper and *Plicatula*. Some of the species of *Spondylus*, as the water-clam (*Sp. varius*), form a series of chambers by secreting successive layers of nacreous shell at a distance from each other, the last chamber containing a quantity of fluid, which escapes by very slow evaporation through the pores of the calcareous shell.

Sponge (Gr. σπόγγος, akin to Lat. fungus, Fr. éponge). In Artillery, a wooden staff, the head of which is covered with sheepskin, and adapted to the form of the chamber or end of the bore of the piece of ordnance for which it is intended. It is used to free the bore from any impurities left by the discharge, or any lighted fragments of the cartridge.

SPONGE. In Commerce, sponge is a cellular elastic albuminous tissue, covered in the living state with a kind of semifluid sarcode. After death, this substance drips or drains away, and leaves merely the sustaining tissue, called *sponge*; formed by the combination of a multitude of small canals, capable of receiving water in their interior, and of becoming thereby distended. The sponges of this kind, called *keratose* or *horny*, occur attached to stones at the bottom of the sea, and abound particularly upon the shores of the islands in the Grecian Archipelago. Sponges afford on distillation a considerable quantity of ammonia; and contain a substance called *fibroine*, which is closely analogous in constitution to silk.

The sponges of commerce are usually prepared before they come to the market, by being beaten and soaked in dilute hydrochloric acid (36 water + 1 acid) with a view to cleanse them, and to dissolve adherent portions of carbonate of lime; but the use of any mineral acid as a solvent is said to deteriorate the quality of the article. The varieties of sponge are very numerous, not less than 250 having been reckoned, but of these only three kinds are met with in commerce, two being derived from Turkey, the third from the West Indies. Turkey sponge is distinguished as *toilette*, the form of which is cup-shaped, the edges of the tubes being fringed with long filaments; or as *honeycomb*, a coarser and more solid variety. The chief mart for Turkey sponge is Smyrna, and quantities varying from 500,000 lbs. to little more than 100,000 lbs. are annually imported from this city. West India sponge is almost valueless, and is imported, it seems, merely to hawk about in the streets and deceive unwary buyers by its apparent cheapness.

Sponge is sold by weight, and many fraudulent devices are adopted among the dealers of the Levant to increase its weight, such, for instance, as laying the fresh sponge on the shore, so that the ripple of the water may fill the pores with fine sand. (*Com. Dict.*)

Sponge. In Natural History, the name of a class of organisms (*Porifera*) which have not acquired the distinctive characters of plants or animals, but consist of sarcode or *gelatinous flesh*, composed of an aggregate of amœbiform bodies, connected and supported, in most of the species, by a spicular framework, which may be silicious, calcareous, or albuminous. The mass, which is commonly amorphous, is traversed by canals, of which those that terminate in the superficial *pores* are *incurrent*, and those that terminate in larger orifices or *oscula* are *excurrent*. The main sign of vitality is the course of currents of water entering by the *pores*, and escaping by the *oscula*. The incurrent streams are nutrient, the excurrent carry out the waste particles and the spores. The latter are ciliate and locomotive, as in some algæ. The movement of the currents is due to ciliary action. The most definitely shaped and beautiful sponges are those of the genus *Euplectella*; the most useful are the *horny* or *keratose* kinds, represented by the *Spongia officinalis* of commerce. Sponges belong to the sub-kingdom *Protozoa*. [Acrita; Amorphozoa.]

Sponge Tent. This material is formed by dipping sponge into hot melted wax plaster, and pressing it till cold between two iron plates: it is then cut into pieces, and used for dilating wounds.

Spongiole. In Botany, the lax cellular tissue and mucus situated at the extremities of roots, having the property of absorbing fluid like a sponge; whence the name.

Sponsions (Lat. sponsio, *a bond*). In International Law, acts and engagements made on behalf of states by agents not specially authorised, or exceeding the limits of the authority under which they purport to be made, are so called by writers on this branch of jurisprudence. Such conventions must be confirmed by express or tacit ratification. The latter is implied from the fact of acting under it as if bound by its stipulations; but mere silence is not, in general, held equivalent to ratification. Such are the official acts of admirals and generals suspending or limiting hostilities, capitulations of surrender, cartels of exchange, &c. (Grotius, *De Jure Bel. et Pac.* lib. iii.; Vattel, liv. ii.; Wheaton *On International Law*, vol. i. p. 291.)

Sponsors (Lat. sponsor, *a surety*). In the Roman Catholic, Greek, Lutheran, and Calvinistic Churches on the Continent, and in the Church of England, the name given to the persons who at the baptism of infants make a profession of the Christian faith in their name, and guarantee their religious education. (Neander's *Church History*, vol. i. part ii.) In the Presbyterian Church, baptism is administered without sponsors.

Spontaneous Axis. Under certain circumstances the motion of a perfectly free body, under the action of instantaneous forces, resolves itself, at the first instant, to a simple rotation about an axis unaccompanied by any motion of translation. When this is the case, the axis is termed a *spontaneous* one. Thus the effect upon a body of a blow whose line of action is parallel to a central principal axis is to cause rotation, for an instant, around a spontaneous axis. (Poinsot 'On Percussion,' in Liouville's *Journal*, 1857.) Euler, in his *Theoria Motus*, 1790; Lagrange, in his *Mécanique Analytique*, Paris 1853; and Delaunay, in Liouville's *Journal*, vol. v., have also written on this subject.

Spontaneous Generation. The notion that corruption is the source of life was, among the ancients, almost universal, and it is a common popular opinion even in the present day. In the scientific world, indeed, the opinion that organised beings can arise without pre-existent germs, has been all but exploded. It has, however, of late been revived; and if the facts brought forward could be implicitly depended upon, the doctrine would certainly be less doubtful than it has of late been considered.

Wherever due attention has been paid, observes Mr. Berkeley, to prevent the possibility of access of atmospheric air, no vegetation has ever appeared, provided proper precautions have been taken to place all possibly pre-existent germs in such a condition that their reproductive powers must be destroyed. If the residue of rain or snow-flakes, or the dust of trade winds, is carefully examined, numerous animal and vegetable productions may always be detected; and the lower forms of either kingdom are propagated with such extreme rapidity, that the swarming of animals or vegetables in *infusions* seems almost magical. Some of these will bear a heat equal or even much superior to that of boiling water for some time without losing their vitality; therefore the simple boiling of water is not sufficient, even if, while it passes through a furnace, care be taken to exclude the outward air or to prevent its containing reproductive germs. Concentrated sulphuric acid has sometimes been used for the same purpose, but this plan is subject to error, as, whatever may be the case with germs which may be present on the outside of a bubble passing through the acid, it does not follow that those in the middle of the bubble should be killed. Experiments, however, have been carried on by M. Pouchet, which appear to exclude all chance of the accidental transmission of germs through the sulphuric acid; but these experiments have been met with counter results of experiments by M. Pasteur. In the present state of the controversy, which is as yet undecided, no general conclusion can be drawn, and more facts are required. Nevertheless, it is apparent that a much larger number of scientific men are now disposed to look favourably on the doctrine of heterogenesis than twenty years ago. The synthesis of *inorganic* and *organic* matter seems within the limits of possibility. (Lindley and Moore, *Treasury of Botany*.) [Species.]

Spool (Ger. spule). A piece of cane or reed, or a hollow cylinder of wood with a ridge

at each end, used by weavers for winding their yarn.

Spoondrift. The light spray blown off the waves in a violent wind.

Sporadic (Gr. σποραδικός, *scattered*). A term applied to such diseases as attack a few persons only at any time or season.

Sporangia (Gr. σπορά, *a seed*, and ἀγγεῖον, *a vessel*). This word is used in cryptogamic Botany, to denote the cases in which the spores are formed. In ferns it is applied to the little cysts with their elastic ring; in pseudo-ferns, to the organs immediately containing the spores, whether naked or contained in a common receptacle; in mosses, to the urn-shaped bodies which are often called *capsules* and *thecæ*. Amongst algæ, lichens, and fungi, it is seldom used in a general sense. In the latter it is sometimes applied to asci when large and pear-shaped as in truffles, to the spore-bearing vesicles of moulds, or to the lens-shaped bodies contained in the receptacles of plants like *Nidularia*, though they are certainly not of the same nature as the organs just mentioned. When the case is so small as to become microscopic, it is sometimes called *sporangiolum*.

Spore (Gr. σπορά). The reproductive bodies of cryptogams. These bodies do not contain an embryo, but consist merely of one or more cells variously combined together; hence, they are called *spores* to distinguish them from true seeds. Amongst *Fungi*, the name is restricted to those reproductive bodies which are produced either singly or in little chains at the tips of the fruit-bearing threads. In many cases, however, these bodies are generated within cells or asci, and they are then for distinction's sake termed *sporidia*. It is, however, desirable that the word *spore* should be used in the more general sense, as opposed to *seed*, the grand distinction between cryptogams and phænogams consisting in the different nature of their mode of reproduction.

The spores of acrogens are produced for the most part in mother-cells four together, after the manner of pollen-grains—often retaining their original form, so that when mature they have one spherical and three plain sides. In a few genera, however, there is only a single spore in each sporangium. In *Algæ* the spores are sometimes nothing more than the transformed joints of certain threads; sometimes they appear to be formed from the contents of a cell, as they are in the ascigerous *Fungi*; sometimes they are endowed with active motion like animals, and are then called Zoospores. In Lichens they are of the same nature as the sporidia of *Fungi*.

Spores or sporules germinate either by elongation of some particular part, and subsequent cell-division, or by cell-division without any protrusion of a thread or membranous expansion. In *Myxogastres* they germinate sometimes after the fashion of other *Fungi*, but sometimes the outer case is ruptured, and a body appears with the attributes of some of the lower *Infusoria*, which, apparently without any cellular division, produces the semi-gelatinous mycelium peculiar to those *Fungi*.

Sporidia (a word coined from Gr. σπορά, and εἶδος, *form*). A term used in describing the spores of *Fungi* and Lichens when they are contained in asci. Sporidia, like spores, may consist of one or more cells, and these may be covered with a distinctly organised cuticle. They have frequently a thick gelatinous coat, which is usually absorbed as the contents of the cells become fully organised. They germinate by the protrusion of the inner membrane, the outer being ruptured or perforated, or in some cases by the elongation of both. In compound sporidia a distinct germinating thread is often produced by each cell. Sporidia are by no means constant in size and form. Great differences of dimensions and outline may exist in the same ascus. They have sometimes a very different outline when seen from the back or side; and in some cases, like the spores of so many Agarics, they are hollowed out on one side like a fragment of a bombshell. In many cases the ascus in which they were generated is absorbed, so that they appear naked; and it is probable that occasionally they undergo further developement when free, as is certainly the case with that of some spores of *Fungi*. These reproductive bodies are sometimes called *sporidiola*.

Sportum, Sportula (Lat.). In Roman Antiquities, a dole. It was an ancient usage in Rome for rich men to distribute victuals on certain occasions among their poor clients, each of whom attended for the purpose with a wicker basket (sportum). Afterwards this dole was generally commuted for money; and the sum thus distributed, about 100 quadrantes, or eighteen pence English, was called *sportula*.

Sporules (Gr. σπορά). The reproductive bodies of Asexual or Cryptogamic plants; differing from seeds in not being generated by impregnation, and in having no definite and predetermined points of growth, but springing forth into young plants from any part of their surface. [Spores.]

Spots on the Sun. [Sun.]

Spottiswoode Press. [Printing Machine.]

Spring (a Teutonic word). In Astronomy, one of the four seasons of the year. For the northern hemisphere, the spring season begins when the sun enters Aries, the first of the northern signs, or about March 21, and ends at the time of the summer solstice. [Seasons.]

Spring. In Mechanics, a piece of mechanism, formed of tempered steel or some other elastic substance, applied mostly for the purposes of producing resistance, or of preventing a shock from the collision of hard bodies, or of giving motion to mechanism by its effort to unbend itself. For the law of the force exerted by a spring, see Elastic Curve.

Spring. In Naval language, a rope or hawser passed from the stern of a ship and made fast to the cable or anchor from the bow

by which she is riding. The object is to vary at will the direction in which she rides, an object of importance when the broadside has to be brought to bear on any given point.

Spring Beam. In the paddle-box of a steam vessel the spring beam is a strong timber parallel to the ship's side, and forming at once the base of the paddle-box and the seat of the plummer-block in which the end of the paddle shaft revolves. It is held in position by the paddle beams projecting beyond the vessel's side. In many modern forms of paddle-box the spring beam is dispensed with, the paddle shaft working in a chock in the side.

Spring Tides. The tides at the times of the new and full moon. At these times the sun and moon are in a straight line with the earth, and their joint effect in raising the waters of the ocean is a maximum, and the tides are consequently the highest. [Tides.]

Springs. Outflows of water or other liquid from the earth. They occur in all parts of the world, in valleys and on hill tops, on land and under water, within caverns, at hill sides, at all levels, and both naturally and after artificial boring through the superficial strata. All water springs are connected ultimately with the rainfall from the clouds, a complete circulation being thus kept up. Oil Springs are connected generally with large deposits of organic matter, either animal or vegetable. Mineral Springs and Thermal Springs consist of water that has passed through the deeper and heated portions of the earth's crust. Springs occur naturally in gravel; at hill sides, where they issue from the edges of strata; or at faults in strata. They are especially common in stratified and limestone districts, but some are found even in granite. [Fountain.]

Springs, Artesian. Vertical perforations of the exterior crust of the earth, of small diameter, and frequently of great depth, through which subterraneous water rises to the surface, often forming abundant and elevated jets. [Artesian Well.] The oldest Artesian well known to exist in France is in the ancient convent of the Chartreux, at Lillers, in Artois. It is said to have been made in 1126. The inhabitants of Egypt and of the great desert of Sahara appear to have been long acquainted with this mode of obtaining water, and the Chinese are said to have practised it for thousands of years.

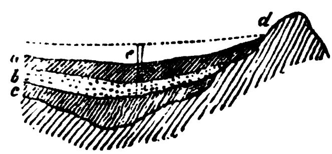
Various conjectures have been made as to the source of the water which comes from the Artesian wells. The simplest and most natural explanation is, that the water is supplied by the rain which falls on the surface at a higher elevation, and which penetrates through the pores and fissures of the ground till it meets with some impermeable stratum, or is collected in subterranean reservoirs. It has been objected that springs are sometimes situated on or near the summits of mountains, which could not be supplied in this way; but on an attentive examination of all the circumstances, i.e. on measuring accurately the extent of surface at a greater elevation than the spring, and comparing it with the quantity of rain that falls annually in the same climate, it has been found, in every instance, that the aqueous deposition from the atmosphere greatly exceeds the supply from the spring. It is computed that not more than a third part of the rain which falls in the valley of the Seine is conveyed to the sea by the river; the remaining two-thirds support vegetation, supply fountains and springs, or are returned to the atmosphere by evaporation. The immense bodies of water which some continental rivers roll towards the ocean are but a small part of the rain which falls in the surrounding countries.

Assuming, then, that the subterraneous water is supplied from atmospherical deposition, it remains to be explained how it arrives at the situation it occupies in the interior of the earth, and by what forces it is raised from great depths to the surface.

All persons who have paid the slightest attention to geology are aware that in stratified countries different beds of rocks are superposed on one another, and ranged in a certain order. The strata sometimes follow a horizontal direction for a considerable extent of country; at other places they are inclined to the horizon, appearing to have been thrust up by the action of a powerful force acting from beneath the surface. In such cases the edges of the strata are often exposed, especially on the summits and flanks of hills, to the action of the atmosphere. Between the strata are frequently found beds of permeable sand, through which water, coming in contact with them, must necessarily pass, first through the inclined part by virtue of its specific gravity, and then in the horizontal branches by virtue of the pressure of the water remaining in the elevated portions of the strata. In such manner the water insinuates itself between the different strata; and hence we may expect that as many distinct sources of subterraneous water will be met with in penetrating perpendicularly through the surface, as there are distinct layers of a permeable nature reposing on impermeable strata. This anticipation is confirmed by experience. M. Arago mentions, that, in digging for coal near St. Nicholas d'Aliermont, a short distance from Dieppe, seven distinct and copious sources of water were found, the respective depths of which were: 1st, between 80 and 100 feet; 2nd, 328 feet; 3rd, from 570 to 590 feet; 4th, from 690 to 710 feet; 5th, 820 feet; 6th, 940 feet; 7th, 1,090 feet; and the occasional force of each source was very great. Similar occurrences are frequent in the neighbourhood of London, and are familiar to all miners. But it is not enough that the structure of the country be such that water can percolate between the different strata: the phenomena of Artesian fountains could not be explained without supposing it to be collected in large quantities, and forming subterraneous reservoirs of immense extent. That such reservoirs exist, no doubt can be entertained. The celebrated fountain

of Vaucluse sends forth at all times a stream of water sufficient to form a considerable river. Even in the driest seasons, when the water is least plentiful, it yields 4,780 cubic feet per minute. After great rains, its product is thrice as great. The mean quantity emitted is 9,360 cubic feet per minute, or about 5,030 millions of cubic feet in a year. Many other examples of the same kind might be cited, showing that water must not only be collected in subterraneous cavities in immense quantities, but that it also passes freely from one place to another. In fact, the disposition of the rocks in strata permits the water to be collected under the surface and to be conveyed without waste, as if in close pipes.

According to the view which has now been taken of the manner in which subterraneous water is collected, its elevation to the surface through a natural fissure or artificial perforation is a simple result of hydrostatic pressure. Generally speaking, the edges of the strata are exposed only on the acclivities of hills, or in elevated places, where, consequently, the rain water can be received under beds of



impermeable materials. Conceive two strata of clay or rocks, as *a* and *b*, having a bed of sand or other matter permeable to water interposed, and suppose that *d* is the place where the edges of the strata crop out, or where a fissure allows a free entrance of the water to the permeable stratum. The water at first descends through the effect of gravity; it then passes along towards *b* in consequence of the pressure exercised by the superior part of the column near *d*. Now, suppose a perforation to be made at *e*, and continued till it reaches through the stratum *a*, the water will naturally continue to rise till it gains the same altitude as *d*, or at least till it reaches the surface if below that altitude. The water, in fact, between the two impermeable strata is in the same circumstances as in an artificial pipe; and if the surface of the ground at *e* is considerably lower than *d*, the ascensional force may be sufficient to cause a considerable jet.

Some Artesian fountains (for example, that at Lillers, in Artois) are situated in the middle of immense plains, where not the most insignificant hill is to be seen on any side. In such cases, it may be asked where we are to look for those hydrostatic columns whose pressure causes the rise of the subterraneous water to the level of the lowest points. The answer is obvious: we must suppose them placed beyond the limits of view; at the distance of 50, 100, or 200 miles, or even at a greater distance. The necessity of supposing the existence of a subterraneous liquid column of two or three hundred miles in extent cannot appear a serious objection, when it is considered that the same geological structure has been found to prevail sometimes over even a much greater extent of country. An interesting paper on this subject is given by Arago, in the *Annuaire du Bureau des Longitudes* for 1835.

Numerous works of this kind have been executed of late years. One of the most remarkable of them is that of Grenelle, a suburb at the south-west of Paris, where there was formerly a great scarcity of water. The strata which were penetrated were: 1. The tertiary strata above the chalk; 2. Chalk; 3. Greensand and clay; 4. Oolite or Jura limestone. The sheet of water flows in a stratum of gravel under the limestone. On account of the great depth of the boring, the work was attended with much difficulty, and retarded by various accidents. At length, in February, 1841, after eight years of exertion, the engineer (M. Mulot) had the satisfaction of seeing the water he was in search of burst forth from a depth of about 600 English yards, and the jet no less than 4,000,000 litres, or in round numbers 880,000 imperial gallons, in the 24 hours. The temperature is 81° of Fahrenheit, corresponding to an increase of 1° for each 20·4 yards of descent. The bore is protected by a metal tube, divided into four unequal lengths, and successively decreasing in diameter. The dimensions are as follow: From the surface of the ground to the commencement of the first tube, 2·5 yards; length of the first tube, 165 yards; of second tube, 227 yards; of third, 72 yards; of fourth, 124 yards; from extremity of last tube to bottom of bore, 7·5 yards; total, 598 yards. The diameter of the first or highest tube is about a foot, and of the lowest about six inches, English. The expense was about 12,000*l.* sterling. For a description of the boring apparatus, and methods of conducting such works usually followed in this country, see Ure's *Dictionary of Arts, Manufactures, and Mines*; and for details respecting some Artesian wells in England, the *Reports of the British Association.*

Springs, Intermittent. In many parts of the world there are springs which sometimes issue freely and are sometimes dry. When this occurs periodically, the springs are said to be *intermittent.*

In limestone districts, springs are due to very different causes from those that act in volcanic districts; and as there are remarkable intermittent springs in both, the explanations must succeed each other.

When large bodies of water exist in hollow spaces and clefts of rock in limestone districts, the means of escape to the surface are often tedious, obscure, and winding, and liable to be partly or entirely choked. It may thus happen that water, having reached a certain point below the surface of high ground (the channels being full), may find the readiest way of escape by means of a kind of natural pipe, which first rises a little and then descends

to a free outlet. In this case, if the delivery pipe is at a lower level than the receiving pipe, and the total rise less than thirty feet, the combination will act as a siphon, and the contents of the reservoir be rapidly drawn off when the siphon acts, and slowly or not at all while the water is rising to such a level as to cause the siphon to begin its action.

Intermittent springs in volcanic districts are very different, and involve the action of steam, probably under high pressure. The geysers of Iceland are fine specimens of such springs. [GEYSERS.] They rise in a tract covered by lava. The Great Geyser springs from a spacious basin at the summit of a mound formed of silicious incrustations deposited by the spray of its waters. In the centre of this basin is a pipe 78 feet deep, through which the water rises, flows over, and is thrown up in jets, attended by loud explosions and subterranean rumblings, and slight tremors of the ground. When these jets are most violent, they shoot to a height of 200 feet; and after playing for some time, a snorting noise is heard, which gradually becomes as loud as thunder, and steam rushes forth with prodigious violence. This deafening roar lasts for a variable time, and the eruption terminates, coming on again after a variable interval of rest.

A satisfactory explanation of these remarkable springs has been offered by Professor R. Bunsen, in his important memoir on pseudo-volcanic phenomena. He refers to the funnel of the geyser, as the main seat of the mechanical force, by which the mass of water is thrown up and converted into boiling foam. The correctness of this he proved by sinking marked stones to different depths; only those suspended near the surface were thrown to a great height. In the lower part of the funnel and in the reservoir below the water, the heat is far above the boiling point. At and near the surface cooling goes on very rapidly. After an eruption, the water falls back in the basin, and, as it rises again, the temperature goes on increasing up to a certain height in the funnel, which is half the height between the surface and the reservoir. When a fresh eruption is about to commence, the temperature approaches to that of the boiling point of the water under the pressure of the column above. At this time a very slight impulse suffices to bring a large portion of the column into a state of ebullition; and the mechanical force thus developed is more than sufficient to raise the huge mass of the water to the great elevation already described. By actual calculation, Professor Bunsen proves that the column of water is fully capable of performing the eruption by the force thus generated. Other intermittent thermal springs are known in Iceland, and of these the Little Geyser is an example. They are due probably to the existence of a subterranean caldron or focus of vapour, and the eruption is caused by the pressure of steam on the roof of this cavern or caldron. This pressure is small immediately after an eruption, but as water pours in and the heat continues, there is no escape, and at length the force becomes sufficient to throw the whole column into the air. The intervals between these eruptions are not very regular.

Springs, Mineral. In many parts of the world, water issues from the earth loaded with mineral matter in solution. The carbonates of lime, magnesia, and soda; sulphates of lime, magnesia, potash, and soda; muriates and chlorides of soda, magnesia, and lime; iron and silica, are the minerals chiefly contained. Carbonic acid gas, oxygen, nitrogen, and sulphuretted hydrogen gases, are also contained sometimes in very large quantities.

Mineral springs often pour forth from the ground, in parts of the earth where there are no volcanic rocks, or any appearance of recent volcanic action. They are, however, usually associated in some way with mechanical disruption of rocks. Thus, the springs at Buxton are near great faults in the carboniferous limestone, and those at Leuk in Switzerland are amongst the High Alps. Many other examples might easily be given. Central France (Auvergne) and the French side of the Pyrenees are especially remarkable for the number of their mineral springs, the volume of the water, and its mineral contents.

Occasionally large quantities of naphtha, or other bituminous fluid, pour out of the earth as springs. These have lately become so important as to require notice in a separate article.

Springs, Naphtha, Oil, and Petroleum. Jets of water containing a large admixture of petroleum and the various minerals allied, such as bitumen, naphtha, and pitch, have long been known, and localities in which fluid bitumen oozes out in large quantities from under water are also known. In one locality on the river Irawadi, there are said to be upwards of 500 such wells, yielding annually half a million of hogsheads of mineral oil; but oil wells such as those that have recently attracted attention in North America are new and remarkable phenomena. The first notices of the existence of oil springs, in North America, in large quantity, appeared about the end of 1858, and two years subsequently 50,000 gallons of valuable produce of this kind were raised daily on the western borders of New York State only. This quantity was obtained from wells sunk from 70 to 500 feet, and the oil was pumped. At the end of 1859 in the state of Pennsylvania, and in the middle of 1860 in Ohio, other oil-yielding districts were discovered, and subsequently Canada, both Upper and Lower, Kentucky, Virginia, Tennessee, Arkansas, Texas, New Mexico, and California, have all been found prolific. Cuba has recently been added to the list of localities. The oil-yielding district reaches from the 65th to the 128th degrees of west longitude from Greenwich, and from near the equator to the 60th degree of north latitude. The oil is derived from Silurian, Devonian, and carboniferous rocks.

The geological position of these oils seems not to be very strictly defined, but it is observed that the main deposit of oil is generally underlaid by tough clay. A violent outburst of carburetted hydrogen gas usually occurs when the oil is reached by boring, and this is followed by a mixture of oil and gas, and afterwards of oil alone, which is sometimes thrown to a height of 100 feet in the air. At the outset, some wells have yielded 4,000 gallons of oil in 24 hours, from a four-inch pipe.

The oils are sometimes clear and transparent, but more usually of a dark brown colour. They are very inflammable, and many accidents have occurred in their use, both at their first issue from the earth and subsequently. These oils are of the nature of naphtha. They generally require distilling, and by slow distillation yield a good lubricating oil, as well as a burning oil and a valuable residuum of paraffine for candles. Benzole is also obtained from them.

At the beginning of the present year (1866), upwards of 50,000 gallons per day were being raised, a great part of which was exported, chiefly to England.

Springs, Thermal. Many springs of hot water rise out of the earth in different parts of the world, besides the remarkable intermittent springs of Iceland. [Geysers; Springs, Intermittent.] The name *thermal spring* is applied only to those cases in which the temperature of the water, as it reaches the earth's surface, is uniform throughout the year, and higher than the mean annual temperature of the air at that point. The following are some of the most remarkable hot springs. At Buxton in Derbyshire, the springs throw out 13,500 cubic feet per day of 24 hours, at a temperature of 82°. At Bath, more than double the quantity, at 115°. At Plombières, in France, the quantity is smaller, but the temperature 147°. At Vernet, in the Pyrenees, the enormous quantity of two and a half millions of cubic feet issue at a temperature of 132°. At Wiesbaden the temperature is 158°; at Carlsbad 167°; at Cantal, in France, as much as 174°; and in the north-west of Spain 192°. Hot springs are known in various parts of Italy, in Portugal, in Greece, Turkey, and the Balkan, in various parts of Asia and Africa, and in both North and South America.

The water of hot springs always contains a certain proportion of solid ingredients held in solution, and generally some gas. The former usually consist of muriates, chlorides, carbonates, and sulphates of lime, soda, and magnesia, but include also iron and silica. Manganese, cobalt, nickel, tin, titanium, copper, lead, silver, and gold have all been detected in springs. As much as 170 grains of solid ingredients are sometimes held in each pint of water. The gases in thermal springs are chiefly carbonic acid, sulphuretted hydrogen, nitrogen, and oxygen. The larger quantities of carbonic acid are of course present in cold, not in hot water. Thermal springs are almost universally valued for their healing powers.

Springing. In Architecture, the lower part of an arch, or that part from which it rises.

Sprit, Spritsail (Dutch spriet, Old Eng. sprit, *to sprout*). A spar or pole. The word was once so used generically. It survives in several terms, notably in *bowsprit*, which is a spar sprouting from the bow. When the word is employed singly, it means a diagonal spar for supporting a quadrilateral fore-and-aft sail, the sprit's heel being against the mast, and its head maintaining the upper corner of the sail farthest from the mast. The spritsail, in particular, was a square sail borne under the bowsprit on the dolphin-striker. It is now obsolete. In very ancient ships there was a sprit-topsail on a mast rising from the outer end of the bowsprit.

Sprocket Wheel. On Shipboard, the sprocket wheel in a capstan is a wheel, armed with pointed studs, round which the chain-cable passes. The studs afford a firmer bite on the cable.

Spruce Beer. A liquor, made of treacle or molasses, and tinctured with the essence of spruce, well boiled in water and fermented.

Spruce Fir. The common name for the trees of the *Abies* family, and specially applied to *A. excelsa*.

Spruce Ochre or **Ocre de Rue.** A dark-coloured yellow ochre, similar to Roman ochre. It is much employed, and affords useful and permanent tints.

Spun Yarn. [Rope.]

Spunk (akin to *fungus* and *sponge*). *Polyporus* (formerly *Boletus*) *igniarius*, a species of fungus, called also Touchwood. The plant, when cut into thin slices and beaten till soft, has been used as a styptic to check hæmorrhage; it is also used, when soaked in a solution of nitre, for kindling matches and tobacco, under the name of Amadou or *German tinder*.

Spurge (Fr. épurge, Ital. spurgo). The common name for the plants of the Euphorbia genus. The Spurge Olive is *Daphne Mezereum*, a deciduous shrub, all parts of which, but especially the fruit and the bark, are very acrid and poisonous; it is used as a sudorific and alterative in medicine, and is sometimes applied externally as an irritant. [Daphne.]

Spurs (A.-Sax. spur). Projections carried out from the banks of rivers to deflect the current and protect the banks; they may be formed either of masonry, carpentry, or brushwood, according to circumstances. They are much employed in defending the banks of the Rhine, the Po, the Danube, the Elbe, &c.; but the French engineers appear to prefer the continuous system of defence afforded by walls, or *pierrés*.

Squad (Fr. escouade). A Military term for a small subdivision of men either for purposes of drill or interior economy.

Squadron (Fr. escadron, Ital. squadra, from Lat. quadratus, *squared*). In the Army, a body of cavalry consisting of two troops. It is the unit of cavalry tactics.

SQUADRON. In Naval matters, a section of a fleet, forming the command of a flag-officer.

Squall (Swed. squal). The Sea term for a gust of wind, or for a short temporary increase in the force of the wind.

Squalus (Lat.). In Ichthyology, the Linnæan generic designation of the shark tribe.

Squama (Lat. *a scale*). In Botany, the bracteæ of an amentum; also used occasionally for any kind of bracted or rudimentary leaf which has a scaly appearance.

Squammipennes (Lat. squama, *a scale*; penna, *a fin*). The name of a family of Acanthopterygious fishes, comprising those which have the dorsal and anal fins covered with scales.

Squameous (Lat. squamosus, *scaly*). In Zoology, when a surface is covered with small scales.

Square (Welsh cwâr, Fr. carré, Lat. quadratus). In Geometry, a four-sided rectilineal figure, of which all the angles are right angles, and all the sides equal.

SQUARE. A Military formation of troops. A *solid square* is formed to resist cavalry, and the men all face outwards. A *hollow square* is formed to hear orders read, &c., and the troops face inwards.

SQUARE. In Naval language, this term is applied to the yards, and implies that they are at right angles to the masts. *Square-rigged* means that the rig includes yards which can be set square. *Square sail* is a quadrilateral sail never borne as a fore-and-aft sail.

Square Measures. The relative magnitudes of squares of given dimensions. [MEASURE.]

Square Number. In Arithmetic, the product of a number multiplied by itself. Thus the squares of the natural numbers, 1, 2, 3, 4, 5, &c., are respectively, 1, 4, 9, 16, 25, &c. Among the properties of square numbers, the following may be mentioned: Every odd square number is of the form $8n+1$, or when divided by 8 leaves 1 for the remainder. Every even square number is of the form $4n$, or is divisible by 4. Every square number ends with one or other of the following digits, 0, 1, 4, 5, 6, 9.

Square Root. In Arithmetic, the square root of any number is the number which being multiplied into itself produces the given number. Thus, 12 is the square root of 144, $\frac{1}{3}$ is the square root of $\frac{1}{9}$, and ·05 the square root of ·0025. When the given number is not an exact square, the root may be found to any degree of approximation by the process for extracting the square root, which is taught in every book of common arithmetic. [QUADRATIC EQUATION.]

Squares, Minimum. [MINIMUM SQUARES.]

Squared Differences of Roots. [EQUATION OF SQUARED DIFFERENCES.]

Squaring of the Circle. [QUADRATURE.]

Squarrose (Lat. squarrosus, *rough and scurfy*, perhaps akin to Gr. ἐσχάρα [ESCHAR]). In Botany, a term applied to those parts of plants which are covered with bodies spreading at right angles, or at a greater angle, from the surface which bears them, or being so arranged, as the leaves of some mosses.

Squash (another form of *quash*, from the root of Lat. quasso, Fr. casser). A variety of *Cucurbita Melopepo*.

Squatina Angelus. [KINGSTON.]

Squill. The root of *Urginea maritima*, formerly called *Scilla maritima*. Squills are imported from the Levant. The roots have a nauseously bitter and very acrid flavour, and are generally cut into slices and dried for pharmaceutical uses. There are two varieties, the red and the white; which, however, do not appear to differ materially in composition. In large doses squill is purgative and emetic; but it is chiefly employed in smaller doses as a powerful expectorant, and as a diuretic in combination with other remedies. Half an ounce of oxymel of squills is sometimes prescribed as an emetic in cases where the bronchiæ are much loaded with viscid mucus, and in the chronic coughs of old people. [URGINEA.]

Squirrel. [SCIURUS.]

Squirting Cucumber. The *Momordica Elaterium* or *Ecbalium agreste*. When the fruit or *pepo* is ripe, it separates from the stalk, and expels its seeds and a thin mucous juice with considerable violence through the remaining aperture. The acrid purgative, known in pharmacy under the name of *elaterium*, is deposited by this juice.

SS, Collar of. So called from the shape of the links; in Heraldry, in silver the badge of an esquire, in gold that of a knight, and, with several varieties in the design, that of various high officials. Its origin, according to Edmonton, 'was, no doubt, religious,' and it is said, in England, to have been originally the cognisance of the house of Lancaster, and introduced in 1407. There seem, however, to be earlier instances.

Stabat Mater Dolorosa. The first words of a celebrated Latin hymn, in rhymed lines of eight syllables without metre; said to have been composed by a Franciscan monk named Jacopone da Todi, in the fourteenth century. It has been set to music by nearly all the greatest composers. The Stabat Mater is performed in the ecclesiastical services of the Roman church during Holy Week.

Stable and Unstable Equilibrium. When a body, in equilibrium under the action of given forces, receives a very small displacement, the points of application and the directions of the forces remaining unaltered, equilibrium may still exist, and if so, it is said to be *neutral*. It may, however, be destroyed, and in this case the original state is called one of *stable* or *unstable equilibrium*, accordingly as, after the displacement, the body tends to return to, or depart still farther from, its former position. Under the influence of gravity, for example, a body is in equilibrium when the vertical through its centre of gravity passes through the point of support, and the equilibrium is stable or unstable accordingly

as a slight displacement causes the ascent or descent of the centre of gravity; it will be neutral if the altitude of the centre of gravity remains unaltered by the displacement. An egg on an horizontal plane may serve to illustrate all three states.

Staccato (Ital. *separated*). In Music, a term denoting that the notes to which it is affixed are to be detached in a marked way from each other, much like SPICCATO.

Stack (Welsh ystac, Dan. stak). Corn in the sheaf piled up in a circular or rectangular figure, brought to a point or ridge at top, and afterwards thatched to protect it from the influence of the weather, and more especially from rains. The term is also sometimes applied to hay piled up in the same manner; which, however, in most places, is called a *rick*. The foundation of a corn stack is commonly made on a platform of wood or iron, raised on props to protect it from the moisture of the soil, and also from rats and mice; differing in this respect from ricks of hay, which are built always on the ground.

Stadium (Gr. στάδιον). In Ancient Architecture, an open space used for athletic exercises. Amongst the Romans, the form of the *stadium* was very similar to that of the *circus*; but most of the Grecian stadia were surrounded by an earthen mound. Vitruvius informs us that the length of a stadium was much greater than its breadth; and that the lists were formed by a terrace, or a bank of earth. Though the stadium mostly formed part of a gymnasium, it sometimes was a part of a separate structure, and was built at great cost and with considerable elegance, as the stadium on the Corinthian isthmus, mentioned by Pausanias, and that of Herodes Atticus, at Athens, which was constructed of Pentelican marble.

STADIUM. A measure of length in use among the ancient Greeks and other nations. It was equal to 600 Greek or 625 Roman feet, or to 125 Roman paces. Hence the stadium contained 606 feet 9 inches, English. (Smith's *Dictionary of Greek and Roman Antiquities*, arts. 'Stadium' and 'Measure.')

Stadtholder (Dutch stadhouder, *city-holder*). The name formerly given to the commander-in-chief of the military forces in the republic of the United Netherlands. William I., prince of Orange, had been made governor or stadtholder of the three provinces of Holland, Zealand, and Utrecht; and during the war of independence he was continued in that office by the goodwill of those provinces. After his death, the earl of Leicester was declared stadtholder by the States-General; while some of the separate provinces appointed Prince Maurice, son of their former governor. For a century and a half afterwards the office was conferred and withdrawn by the several provinces at many different times, although always confined to members of the house of Orange. William IV. prince of Orange, in 1747, was the first general hereditary stadtholder; in 1794, the office ceased on the French conquest; in 1814, the head of the house of Orange was raised to the throne by the title of King William I.—a title retained by his successors. The power of the stadtholder varied in different provinces, and at different periods.

Staff (A.-Sax. stæf). The staff of an army consists of the officers charged with the administration of the various departments of the service. The following is the staff of the British army:—

1. General officers or colonels commanding divisions, districts, brigades, &c.
2. Adjutant-general's department. [ADJUTANT-GENERAL.]
3. Quartermaster-general's department. [QUARTERMASTER-GENERAL.]
4. Personal staff, consisting of military secretaries, assistant military secretaries, and aides-de-camp.

Officers for the staff other than personal staff must either pass through the staff college, or undergo the final examination laid down for the particular appointment, except those who attained the rank of lieutenant-colonel before January 1, 1860, or have proved their abilities in the field. Officers of the Royal Engineers are exempted from these rules.

The duties of brigade major, town or fort major, fort and garrison adjutant, correspond to those of officers of the adjutant-general's department at their respective commands.

There is also a staff, viz. adjutant, quartermaster, &c., to each regiment.

STAFF. In Music, the five lines with the spaces between them, on which music is written.

Staff Angle. In Architecture, a square rod of wood, or, in modern practice, of Keene's or Parian cement, standing flush with the finished plastering of the wall on either side, at the external angles of the plastering of the rooms, in order to oppose the tendency of the usual rendering to chip. Sometimes the staff beads are executed of copper or zinc.

Staff College. In the British Army, the school of instruction for officers who wish to be placed upon the staff of the army. It was founded in 1858, and a general order of August 25, 1863, details the qualifications necessary for admission. These are, briefly: a previous service of not less than three years; a certificate as to character and efficiency from the commanding officer; a certificate of good health and fitness for active duties from a military surgeon; a certificate of having passed the examination for the rank of captain. The candidates undergo a competitive examination in mathematics, modern languages, surveying, and military history, and the successful ones undergo a course of two years' study in the same and other subjects at the staff college. There is then a final examination, after which each officer is attached for a short time to each of those branches of the service to which he does *not* belong. He is then qualified to hold a staff appointment. There are always thirty officer students at the Staff College.

Stag. [DEER.]

Stag Beetle. The largest of British beetles (*Coleoptera*), so called on account of the length, thickness, and shape of the mandibles of the male, which resemble the antlers of a young stag, and are peculiar to the male sex. This insect (*Lucanus cervus*, Linn.) abounds in some wooded localities of the southern counties, flying about in the summer evenings, especially round the oak, on the wood of which the larva feeds, burrowing therein and passing several years in that stage of existence before its final transformation.

Stained Glass. [GLASS PAINTING.]

Stairs (A.-Sax. stæger). In Architecture, steps leading from the lower to the upper part of a house. When these are surrounded with walls or balustrades, with landing-places for the resting of the person ascending, or for communication between the several stories of a building, the whole is called a *staircase*. Vitruvius makes no mention of staircases in his treatise upon architecture; and indeed with the ancients they formed no part of the interior decoration, being generally upon the outside of the buildings. Those of which traces survive are narrow, and in some cases the steps are at least a foot in height. In modern architecture, those stairs which proceed in a right line of ascent are called *fliers*. When the steps wind round a solid or open newel, they are called *winders*. Mixed stairs are partly composed of flying and winding steps. Rondelet, after an examination of the most celebrated staircases, stated that the best proportions of the width of the tread to the rise of the steps was ascertained by the formula

$$2\,h + w = 2 \text{ ft. } 2 \text{ in.}$$

in which h would represent the height of the rise, and w the width of the tread; the length 2 ft. 2 in. being the length of the average pace of a man walking on even ground.

Stalactites (Gr. σταλακτίς, *that which drops*). Conical or cylindrical concretions of carbonate of lime attached to the roofs of calcareous caverns, and formed by a gradual dropping of water holding the carbonate in solution.

Stalagmite (Gr. σταλαγμός, *a dropping*). Stalactical formations of carbonate of lime found upon the floors of calcareous caverns, and due to the deposit of carbonate of lime from the evaporation of water fallen from the surface.

Stalk (Swed. stielk, Gr. στέλεχος). In Architecture, an ornament resembling a stalk in the Corinthian capital from which the volutes and helices spring. It is sometimes fluted.

The word *stalk* has lately been applied to the *chimney stalks*, carried up to a great height above the roofs of the buildings with which they are connected.

Stall (A.-Sax.). In Architecture, a seat raised on the sides of the choir or chancel of a church. Stalls are sometimes placed near the high altar for the priest and deacon or subdeacon; they are then called *sedilia*. At St. George's Chapel, Windsor, a stall is appropriated to every Knight of the Garter after his election and installation.

Stall-feeding. Cattle kept in stables and tied up separately, their food being brought to them, are said to be *stall-fed*. The advantages of this mode of fattening cattle are very great, both to the farmer or feeder and to the public; because much less food is wasted, and a much greater quantity of manure is produced. The disadvantages are, that more manual labour is required for cutting and carrying the food from the field to the stable; and that the flesh of the animals, for want of exercise, is not considered so high-flavoured as that of cattle which have pastured at large. To remedy this defect of stall-feeding, it is well, instead of rendering the animals fixtures by tying them up to stakes, to put them individually in so-called *boxes* about ten to twelve feet square, or to put two or three together in small yards, with a shed at one end, in which they may take exercise, shelter, or repose, according to their inclination. By this mode an equal quantity of manure is produced with less labour, and the flesh of the cattle is reckoned wholesome. When herbage plants, or grasses, are cut over only two or three times in the course of a season, instead of being continually cropped by the bite of cattle during the whole summer, the amount of vegetable produce is found to be much greater, because the plant while growing perfects a sufficient number of leaves to nourish the root; and when this produce is given to cattle in racks, in stables, sheds, or small courts, much less of it is wasted than if it were eaten on the spot where it grew. Hence, any given surface of cultivated land will produce a much greater quantity of butcher meat under crops to be mown than under herbage to be pastured; and stall-feeding, therefore, is one of the greatest modern improvements in husbandry. There can be little doubt that, with the progress of rural improvement, it will ultimately become universal; and then, and not till then, will the butcher meat of warm climates be equal to that of such climates as that of Britain. In warm climates, at present, cattle cannot be fattened by pasturing.

Stall-plate. In Heraldry, a square or oblong plate of gilt copper, upon which the arms of Knights of the Garter and of the Bath are emblazoned, and fixed in their stalls in the chapels of St. George at Windsor and of Henry VII. at Westminster. The plates now in existence date from the beginning of the reign of Henry VI., and are of great historical value.

Stallage. In Law, a duty paid for the liberty of setting up movable stalls or tables, or the like, in a fair or market; due to the owner of the soil as such, to set up stalls without whose license is trespass. When the stalls are fixed into the ground, the duty is termed *pickage*.

Stamens (Lat. stamen). In Botany, the male apparatus of a flower. The stamens are situated immediately within the petals, and

consist each of the filament, the anther, and the pollen, of which the two latter parts are essential, and the former not. They are a modified form of the petal, and are placed next it on the inside towards the centre of the flower. Independently of their physiological importance, they are much used as good marks of discrimination in systematical botany.

Staminidia (Lat. stamen). Those bodies which are supposed to be, in *Hepaticæ* and other Cryptogamic plants, the equivalent of anthers in more perfect plants.

Staminodium. In Botany, a term applied to an abortive or rudimentary stamen, or to an organ which from its position and form appears to be such. It is readily seen in the form of a scale on the corolla of *Scrophularia*.

Stammering (A.-Sax. stamer, Ger. stammeln). A term vaguely used to denote all kinds of defective utterance; but more strictly it may be described as an organic or symptomatic affection, as distinguished from *stuttering*, which is chiefly idiopathic or functional. The former is a difficulty in uttering certain elementary sounds; the latter is chiefly a difficulty in the fluent enunciation of words and sentences. Owing to the many anomalous forms which stuttering may assume, the number of remedies suggested has been very great. See an article on 'The Irrationale of Speech,' in *Fraser's Magazine* for July 1859.

Stamps. In Finance, an expedient by which a revenue can be derived from legal and other instruments, either by impressing paper, or by inserting or attaching some fabric to parchments, and providing either that the instrument shall have no legal authority except it bear this impression, or that penalties should be levied on those who construct instruments from which these government impressions are absent.

The invention of stamps as a means of revenue is ascribed to the Dutch war of independence in the sixteenth century, a crisis which was fruitful in financial expedients. They were first introduced into England by 5 & 6 Wm. & Mary c. 21, and were rapidly extended to every possible object. They were imposed on bills and notes in 1782, on foreign bills and receipts in the following year, and with some exceptions (as those on newspapers and pamphlets) have been retained in a modified form in our own time. In the case of newspapers, the stamp releases the paper from the charge of postage, to which if the stamp be not annexed the newspaper is still liable.

The word *stamp*, as is well known, is also applied to the adhesive labels affixed to letters, and first introduced after the post-office reform of 1840, though here it merely signifies a payment for a specific service.

Properly speaking, a stamp is a tax on contracts, and with rare exceptions is of doubtful expediency, because unfair and unequal in its incidence. There can be no reason, for instance, in burdening the conveyance of land, still less a pledge of land by mortgage, with a heavy tax, and exempting the transfer of other kinds of property, as merchandise, from such a liability. And the unfairness of the tax on conveying land is the more marked, because no tax was levied till lately on the succession to land, and even now the tax is lighter than that on succession to personal property. But of all taxes, none is primâ facie more just than a tax on inheritances.

The manner in which the stamp duties are chiefly secured is by prohibiting the reception of instruments in evidence unless they bear the stamp required by the law. It has consequently not unfrequently been the case, that an innocent mistake in interpreting a fiscal regulation has proved fatal to a just claim—the instrument on which the claimant relied being found to have been improperly stamped. This has been partially remedied by the Common Law Procedure Act 1854, which renders such instruments admissible in some cases on payment of the stamp duty, and a penalty, to the proper officer of the court. An unstamped instrument, though inadmissible in evidence of its contents, may yet be received in evidence for some collateral purposes, as to show illegality or fraud, and unstamped instruments are now admissible in evidence in criminal proceedings.

The all but universal evasion of the stamp duties leviable on instruments of simple contract, as bankers' drafts and receipts, led the government a few years since to substitute a uniform penny stamp in lieu of the graduated duties previously payable. No doubt this tax is not strictly defensible, as no uniform duty can be; but it is acquiesced in, partly because the amount is trifling, and, in part, because it is a relief from another system which would have been extravagantly oppressive had it not been notoriously evaded. The alteration in the stamp duties on drafts and receipts was strenuously urged on the government, by an eminent member of the Society of Friends, the late Mr. Christie. [Taxes.]

Stamper Press. A machine, of Dutch origin, used for the purpose of expressing oil by pressure through the interstices of bags. The stamper consists of a long rectangular box open at the top; at each end there are two plates, between which one bag of seed is placed, yielding a cake of 9 lbs. Next to one of the inner plates is a filling-up piece, then an inverted wedge, then another filling-up piece, after which is introduced a vertical driving-wedge, and, lastly, another filling-up piece is inserted between the driving-wedge and the other inner plate. As soon as the bags have been placed vertically in the press-box, a stamper made of hard wood, about 16 feet long and 8 inches square, with a descent of about 22 inches in the final stroke, is allowed to fall at the rate of 15 strokes per minute for a period of about 6 minutes upon the head of the driving-wedge. This is sufficient to drive it down level with the top of the press-box, the stamper being worked by two cams, or wipers, on a revolving shaft.

Side by side with the first stamper is a second one, immediately above the inverted wedge, which is held suspended at a fixed point by means of a lever, while the first stamper is in action; but as soon as it is time to remove the bags, the first stamper is raised by means of a lever above the point at which the cams come in contact with it, and by the same means the other stamper, which was previously suspended, is allowed to fall upon the inverted wedge, driving it downwards, and thereby releasing the working wedge, so that the attendant may remove the bags and repeat the operation. A press like this will do 12 cwt. of cake per day. (Fairbairn's *Mills and Millwork.*)

Stanchions. The Sea term for upright supports in general.

Stand. A Sea term, used variously; as, for example, a sail is said to *stand* well or ill. A ship is said to *stand* towards or from the shore or any object (for to *sail*). To *stand on*, to continue the course. To *stand by*, to be ready.

Standard (Ital. stendardo, Fr. étendard). In Botany, the upper and erect petal of that form of corolla which is called *papilionaceous*, from its fancied resemblance to a butterfly.

STANDARD. In Heraldry, a large square flag bearing the whole of the achievements of the monarch or nobleman, as seen in the royal standard of England. In ancient times, the royal standard, when placed before the pavilion of the monarch, either at a tournay or at an encampment, was eleven yards long and three yards broad. The length of the standard when borne in the field denoted the rank of the leader; that of a duke was seven yards long; that of a peer of lower degree, five yards; that of a knight-banneret, four. In modern times standards of peers or knights-bannerets are seldom displayed but in funeral processions. They are then long and narrow, and pointed at the ends; that of a duke is about fifteen feet in length, that of peers of lower degree, about twelve.

STANDARD. In Shipbuilding, a bracket or knee situated *above* the object to which its horizontal arm is bound.

STANDARD. A flag intended to be borne in battle. At present, in the British service, the term is applied only to the flags of cavalry regiments, other than dragoons or dragoon guards. Cavalry standards are of silk, and each regiment has two—the first or royal standard crimson, with a device upon it; the second or regimental standard of the colour of the facing of the regiment, with a different device.

Standard Measures of Length. [WEIGHTS AND MEASURES.]

Standard of Money. [MONEY.]

Stanethyl. An organo-metallic body containing tin and the organic radical ethyl.

Stanislaus, St., Order of. A Polish order of knighthood, founded by Stanislaus, king of Poland, in 1765, and renewed by the emperor Alexander in 1815.

Stannaries (Lat. stannum, *tin*). The stannary courts of Devon and Cornwall are courts of record for the administration of justice among the tinners. They are of very ancient date, and were confirmed in 33 Edw. I. They are held before the vice-warden. The appeal from the vice-warden lies to the lord warden, assisted by legal assessors, and thence to the Judicial Committee of the Privy Council.

Stannic Acid. Peroxide of tin.

Stantion, called also **Stemson.** In a wooden vessel, a timber rising within the stem, or within the apron. It forms an inner stem, and adds greatly to the strength of the fore-part of the ship. It is united by a scarf joint to the keelson.

Stanza (Ital. *station*). In Poetry, a series or number of verses connected with each other in a poem, of which the metre is constructed of successive series similar in arrangement. The stanza, however, must be understood to form a shorter division than the classical strophe, to which this definition would be equally applicable. It is so called from terminating with a full point or pause. The *ottava rima*, which consists of six lines in alternate rhyme ended by a couplet, the lines being decasyllabic or rather hendecasyllabic, is the principal Italian stanza. [OTTAVA RIMA.] The Spenserian stanza (which was perhaps invented by the poet from whom it derives its name, but certainly first applied by him to the construction of a regular poem) consists of eight decasyllabic verses and an Alexandrine at the end; the first and third verses forming the first rhyme; the second, fourth, fifth, and seventh, another; and the sixth, eighth, and ninth, a third rhyme.

Stapelia (after Dr. J. B. à Stapel, Dutch editor of Theophrastus). A genus of South African succulent-stemmed leafless *Asclepiadaceæ*, chiefly remarkable for the curious wrinkled toad-like appearance of their handsomely marbled or mottled star-shaped flowers, and the disgusting carrion-like scent emitted by most of them.

Stapes. A stirrup. One of the bones of the internal ear is so called, from its shape.

Staphyleaceæ (Staphylea, one of the genera). A small group of polypetalous *Thalamifloræ*, formerly united with *Celastraceæ*, but now recognised as having the essential characters of *Sapindaceæ*, and added by many botanists to that order as a tribe distinguished by the stamens being inserted outside instead of inside the disc, and by albuminous seeds. They consist of trees or shrubs, which are natives of Europe, Asia, and northern and tropical America.

Staphyloma (Gr. σταφύλωμα). A disease of the eyeball, in which the cornea becomes opaque and tumid, forming a white projection, sometimes resembling a grape in shape; it occasionally increases to a great extent, and requires to be removed by an operation.

Staple (Low Lat. stapulum, said to be derived from an old French word estape, signifying a mart for wine, wine being the principal

product of France). In mediæval times, certain products in the supply of which this country possessed peculiar advantages, were called *staples*, and the market for such kinds of produce was carefully regulated. Thus, wool and hides were staple agricultural produce, the sale and exportation of which were put under various limitations and conditions, the prices being fixed by statute or proclamation. So, again, tin was a staple in Cornwall, lead in Derbyshire; and on many occasions an exact control was exercised over these goods, sales being restricted to particular localities, and occasionally prohibited. Such prohibitions were, up to a comparatively late period, laid on the export of wool, and extreme penalties inflicted on those who evaded or broke the law.

In order to give importance to Calais, Edward III. fixed the staple of wool at this town; i. e. the price at which the article could be purchased by foreign buyers, especially by the weavers of the Low Countries, was determined by the rates prevailing in the Calais market. Of course there were many qualities of wool, and therefore very various prices; but the rate at which sales were effected at Calais regulated, either directly or indirectly, the market value of all wool at other marts.

The mayor of the staple was an important officer, intrusted with the maintenance of the regulations laid on staple trades. He was also empowered to take the recognisance known under the name of STATUTE STAPLE, by which a merchant, when ordinary conveyance of land was illegal, was enabled to pledge his estate for the payment of debts, and so to raise funds for carrying on his trade.

Star (Gr. ἀστήρ, ἄστρον, Lat. astrum, Ger. stern: for some remarks on the history of the word, see RISHIS). In a popular sense, the word *star* is used to designate any celestial body whatever, including the planets; but in Astronomy it is applied to those self-shining bodies, constituted like the sun, situated at almost infinite distances from us, and doubtless, like our sun, the centres of systems similar to our own.

One of the first results of the observation of the heavens was the discovery that the stars maintain always the same positions relatively to each other. Hence, they were called *fixed stars*, in distinction to the *planets* or *wandering stars*, which are constantly changing their places in the firmament. The fixity of the stars is, indeed, not absolute, for modern observations have detected changes of relative position among them; but these changes are so minute, that in general they become sensible only after the lapse of a number of years, by a comparison of position determined with the most perfect instruments at the beginning and end of the interval. They are consequently altogether inappreciable to unassisted vision, and the discovery of their existence has not rendered a change of language necessary: astronomers still speak of the *fixed stars*.

Apparent Magnitude of the Stars.—The first circumstance which arrests the attention of the observer of the stars, is the great difference in their apparent magnitudes or their relative brightness. In order to establish a gradation in this respect, and for the convenience of description and reference, astronomers divide them into classes or orders, which are called *magnitudes*. A few of the most brilliant are denominated stars of the *first magnitude*; those of an inferior degree of brightness are of the *second magnitude*; and so on down to the 6th or 7th, which, according to the established convention, comprehend the stars visible to the naked eye. The gradation is, however, still continued among those which are visible in the telescope, and magnitudes from the 8th to the 16th are familiar to those who are in the practice of using powerful instruments. It is, however, to be remarked, that this classification is not based on any photometrical determination, but is entirely arbitrary. 'Of a multitude of bright objects,' says Sir John Herschel, 'differing, probably, intrinsically, both in size and splendour, and arranged at unequal distances from us, one must of necessity appear the brightest, one next below it, and so on. An order of succession *must* exist; and it is a matter of absolute indifference where, in that infinite progression downwards from the brightest to the invisible, we choose to draw a line of demarcation. All this is matter of pure convention. Usage has, however, established such a convention; and although it is impossible to determine exactly, or à priori, where one magnitude ends and another begins, and although different observers have differed in their magnitudes, yet, on the whole, astronomers have restricted their first magnitudes to about 15 or 20 principal stars, their second to 50 or 60 next inferior, their third to about 200 yet smaller, and so on; the numbers increasing very rapidly as we descend in the scale of brightness, the whole number of stars already registered, down to the 7th magnitude inclusive, amounting to 15,000 or 20,000.' ('Astronomy,' *Cabinet Cyclopædia*, p. 374.)

The method of estimating the apparent magnitudes, therefore, usually adopted is by a scale of brightnesses decreasing in geometrical progression, each term being half of the preceding, or at least having a fixed ratio to it. Sir J. Herschel proposes and recommends the adoption of a scale decreasing as the squares of the terms of an harmonic progression, viz. the series $1, \frac{1}{4}, \frac{1}{9}, \frac{1}{16}, \frac{1}{25}$, &c. This scale is not a purely photometric one, like the former, but involves the physical idea of supposing the scale of magnitudes to correspond to the appearance of a first-magnitude star removed successively to twice, three times, four times, &c. its original or standard distance: so that upon the supposition of an equality among the real lights of the stars, the nominal magnitude would be a sort of index to the presumable distance.

Arrangement and Nomenclature of the Stars.—In order to indicate the quarter of the heavens in which any star is situated, astronomers, in

the earliest ages of the science, had recourse to the method of forming them into groups, to which they gave the name of *constellations* or *asterisms* [CONSTELLATION], and distinguished the different groups one from another by appellations borrowed in general from mythology, and suggested by vague resemblances or fanciful analogies, the origin of which it is now difficult or impossible to trace. A few of the brightest stars received particular names; some of which, conferred by the Greeks and Arabs, have been preserved, as Sirius, Rigel, Aldebaran, Arcturus, Capella, &c.; but it is obvious that this nomenclature could not be carried to any great extent. The system which has prevailed in modern times, and been generally adopted by astronomers in their charts and catalogues, was invented by Bayer, whose *Uranometria*, containing charts of all the constellations, was first published at Augsburg in 1603. It consists in distinguishing the stars belonging to each constellation by the letters of the alphabet, beginning with the brightest, which is called α. The next brightest is called β, the next in order of brightness γ, and so on; and when the letters of the Greek alphabet were exhausted, Bayer had recourse to the Roman, and then to the Italian. It is to be observed, that the order of the letters indicates only the relative brightness of stars in the same constellation, without reference to other parts of the heavens. Admitting the principle, it might have been simpler to have employed the ordinal numbers 1, 2, 3, 4, &c. for distinguishing individual stars. But great perplexity is caused by the irregular forms of the constellations, whose numerous contortions and interlacings with each other baffle the efforts of memory, and which seem, as Sir J. Herschel remarks, 'to have been purposely named and delineated to cause as much confusion as possible.'

Distribution of the Stars.—The stars are very irregularly distributed over the celestial sphere. In some regions spaces of considerable magnitude occur in which scarcely a single star is to be seen, while in others they are crowded together, so as to present to the unassisted eye the appearance of a confused mass of light. A great and rapid increase of number is in general perceptible as we approach the borders of the Milky Way, where they appear, when viewed through a powerful telescope, to be crowded almost beyond imagination. Besides the general increase which takes place towards this region, there are in several parts of the heavens patches or clusters of stars, where great numbers are condensed into a very narrow space. A telescope turned upon the Pleiades shows fifty or sixty large stars crowded together within a small area, and comparatively insulated from the rest of the heavens. Another occurs in the constellation Cancer, and is called Præsepe, or the Beehive, from the great number of stars which it presents in the telescope. In the sword-handle of Perseus and in Hercules there are also groups of the same kind, perhaps the most glorious of such objects, in which the individual stars can be distinguished in a telescope of moderate power; and in various parts of the heavens there are found luminous spots in which no star can be distinguished with ordinary telescopes, but which, when viewed through very powerful instruments, are found to consist of stars crowded together so as to occupy almost a definite outline. Many of them, says Sir J. Herschel, 'are of an exactly round figure, and convey the complete idea of a globular space filled full of stars, insulated in the heavens, and constituting in itself a family or society apart from the rest, and subject to its own internal laws. It would be a vain task to count the stars in one of these *globular clusters*. They are not to be reckoned by hundreds; and on a rough calculation, grounded on the apparent intervals between them at the borders (where they are not seen projected on each other) and the angular diameter of the whole group, it would appear that many clusters of this description must contain at least ten or twenty thousand stars compressed and wedged together in a round space, whose angular diameter does not exceed 8 or 10 minutes; i.e. in an area not exceeding the tenth part of that covered by the moon.' (*Astronomy*, p. 400.)

Number of Visible Stars.—As no limit can be set to the distance to which the stars may extend in space, the number of visible stars is limited only by the powers of the telescope. But the direct enumeration is beyond human power; and in order to obtain an approximation, it is necessary to have recourse to hypothetical considerations. By a very ingenious investigation, founded on the numbers ascertained by Sir W. Herschel to exist within certain limited spaces, Struve has attempted to compute the whole number in the heavens within the range of the twenty-foot reflector. He first establishes a law of diminution depending on the angular distance from the plane of the galactic circle [GALAXY], and having ascertained the mean number visible in the field of the telescope in that plane, he finds, by a process of integration, the whole number in the celestial vault to be upwards of twenty millions. Whether this number be near or far from the truth, it must be taken as the most probable estimate yet made. M. Chacornac, however, estimates at 77,000,000 the stars comprised in the first thirteen magnitudes.

If we confine our attention to stars visible to the naked eye, the number may be estimated with greater precision. The number of stars of the several magnitudes, in the northern hemisphere, contained in Argelander's catalogue, is as under:—

Magnitudes .	1	2	3	4	5	6
Stars in each .	9	34	96	214	550	1,439
Sums . .	9	43	139	353	903	2,342

Assuming the *density* to be the same in the southern hemisphere as in the northern, the catalogue should contain 4,684 stars. It is estimated by Struve, that the number entered

in the catalogue is to the whole number existing (and visible to the naked eye) within a given space, in the ratio of 8,136 to 10,000. Hence the whole number of stars which can be seen with the naked eye is 5,757, i. e. less than 6,000. The number of stars down to the ninth magnitude already registered and mapped amounts to nearly 300,000.

Distance.—Although it is a very improbable supposition that all the stars are of the same size, it is equally improbable that their real magnitudes are in any way dependent on their distance; but unless this latter supposition be made, we must conclude that, *on the average* (putting individual cases out of view), the most distant will be those which have the smallest apparent magnitude.

Argelander, of Bonn. has given a catalogue of the stars visible to the naked eye, in which they are divided into six orders of magnitude; the faintest stars, or those just perceptible by the naked eye, being considered as the smallest, or the sixth magnitude. If we suppose six concentric spheres to be described about the sun, with radii such that the first contains all the stars of the first magnitude, the second all those of the first and second magnitude, the third all those of the first three magnitudes, and so on; and if we also suppose the *mean* distance of the stars of the first magnitude to be unity, then, according to the computation of Struve (founded necessarily on certain hypothetical assumptions respecting the distribution of the stars in space), the mean distance of the stars of the different orders of magnitude, and the radii of the spheres circumscribing them, as above supposed, are as follow:—

Magnitudes	Mean Distance	Radius of Sphere
1	1·0000	1·2638
2	1·8031	2·1408
3	2·7639	3·1961
4	3·9057	4·4374
5	5·4545	6·2093
6	7·7258	8·8726

For stars of the next three magnitudes, the data for computing the relative distances have been furnished by Bessel's zone observations. Struve finds the radii of the circumscribing spheres to be as follow: For those of the seventh magnitude, 14·4365 units; for those of the eighth 24·8445; of the ninth 37·7364; and, lastly, he concludes that the smallest stars observed by Sir William Herschel with his twenty-foot reflector are at an average distance of 227·8 units, or 25·67 times more distant than the smallest stars visible to the naked eye. (*Etudes d'Astronomie Stellaire*, p. 81.) So much for estimation. The element from which the distance can be actually deduced is the annual parallax, or the angle subtended by the diameter of the earth's orbit at the distance of the star [PARALLAX]; this distance is so great that, except in a few instances, all the attempts of astronomers to determine it have hitherto been fruitless; in other words, at the distance of the star, the diameter of the earth's orbit, a line some 180,000,000 miles long, is not of sensible dimensions. We know, for instance, that from α Centauri the radius of the earth's orbit would be hidden by a thread $\frac{1}{25}$ of an inch in diameter, held at a distance of 650 feet from the eye.

We give below a table of the principal distances already determined, expressed in radii of the earth's orbit; they can be converted into miles by multiplying them by the length of that radius.

The number of years required by light to travel the different distances is also shown:—

	Radii of Earth's Orbit	Years
α Centauri . . .	211,330	3·6
61 Cygni . . .	550,920	9·4
Vega.	1,330,700	21·0
Sirius	1,375,000	22·0
ι Ursæ Majoris .	1,550,800	25·0
Arcturus . . .	1,622,800	26·0
Polaris	3,078,600	50·0
Capella	4,484,000	72·0

The distances of other stars are also known, but with less precision. None, however, are less than the distance of α Centauri. It is no extravagant supposition that there may be others still visible which are a thousand times more remote. If, therefore, one of these were annihilated, some ten thousand years would elapse before its extinction could be perceived at the distance of the earth.

Real Magnitudes.—The only means formerly possessed of obtaining any indication respecting the real magnitudes of the stars was by means of the quantity of light received from them. Sir J. Herschel compared the light of α Centauri directly with the moon, and from several experiments, made with attention to all the circumstances required to be taken account of, found that the mean quantity of light radiated to the earth by a full moon exceeds that sent by α Centauri in the proportion of 27,408 to 1. Dr. Wollaston (*Phil. Trans.* 1829) found the proportion of the sun's light to that of the full moon to be that of 801,072 to 1. Combining these results, it appears that the light sent to us by the sun is to that sent by α Centauri as 21,955,000,000, or about twenty-two thousand millions to one.

A knowledge of the distances of the stars does not help us to determine their real dimensions, as has been done in the case of the planets and the sun, for the apparent diameter of the most brilliant stars is so small that it defies all measurement.

If, however, we suppose that the intrinsic intensity of the light be the same for Sirius (for example) as for the sun of our system, we shall arrive at pretty clear, if only conjectural, views on the dimensions of this magnificent star. On this hypothesis, the diameter of Sirius would be fifteen times that of our sun; so that, even in granting to its light an intrinsic brightness triple that of the sun, the dimensions of Sirius would still be five times greater, and its volume would be 125 times that of the sun.

Proper Motions of the Stars.—On comparing

the places of the stars determined by recent observations with the positions assigned to them in the older catalogues, it is found that many of them have undergone a very sensible displacement. Within the last fifty years the double star 61 Cygni, above mentioned, has moved through 4′ 23″ of right ascension; and as the motion appears to be uniform, its rate is therefore about 5·3″ annually. Another star (μ Cassiópeiæ) has an annual proper motion of 3·74″. The number of stars in which such motion has been detected, though of smaller amount than in the above instances, is very considerable. Out of 2,959 stars in the catalogues of Bradley and Piazzi, Bessel found 425 having a proper motion of not less than 0·2″. The discovery of the existence of such changes in the places of the stars gives rise to some interesting speculations relative to the constitution of the universe. That the stars gravitate to each other like the bodies of the solar system is rendered certain from the phenomena of binary stars; and when we admit the prevalence of this force among them, we are led to suppose a centrifugal force to be necessary to counteract the tendency to a general collapse produced by their mutual gravitation. Hence, we conclude that the proper motions must be performed in circular or elliptic orbits round some very remote centre; and as every appearance leads us to suppose the stars to be bodies of the same nature as our own sun, it becomes extremely probable that the sun with its attendant system is transported through space with a similar motion. Now, the translation of the solar system would necessarily give rise to an apparent change of the positions of the stars; for in consequence of the diminution of distance, they must appear to recede from that point of the heavens towards which the sun's motion is directed, and to converge and become more condensed in the region diametrically opposite. Sir William Herschel was of opinion that this is what actually takes place, and that a general recess of the principal stars from the point occupied by ζ Herculis is already indicated by the catalogues, and consequently that the solar system is carried forward in the direction of that star. It seems, however, to be the opinion of astronomers at present, that the observations are not yet sufficient to establish the certainty of this motion; but whether the supposition shall be confirmed or not, it would appear that all the proper motions which have been remarked cannot be accounted for in this way. It is a curious circumstance, and was first noticed by Bessel, that a large proportion of the stars which have a proper motion are double stars. The most decided case of proper motion lately recorded is that of Sirius, which is now known to have one or more companions.

Arcturus in a century traverses the eighth part of the diameter of the moon. α Centauri, in the same interval of time, is displaced a quantity measured by the fifth of this diameter.

To determine the real velocity of a star from the proper motion, the distances of the stars of which the proper motion is measured must be known. We give a table of some velocities which have been thus determined:—

	Miles per second
Arcturus	54
61 Cygni	40
Capella	30
Sirius	14
α Centauri	13
Vega	13
Polaris	1½

Variable and Periodic Stars.—Proper motion is not the only indication of the existence of active forces in the stellar regions. Many stars have been observed whose light appears to undergo a regular periodic increase and diminution of brightness, amounting in some instances to a complete extinction and revival. Of this kind one of the most remarkable is the star *Omicron* in the constellation Cetus, or the Whale, which has a period of about 334 days. At its greatest brightness it is a star of the second or third magnitude, and continues in this state about a fortnight, when its light begins to wane, and at the end of three months it becomes for some time invisible to the naked eye. Algol, in the constellation Perseus, appears for about 62 hours as a star of the second magnitude; its light then suddenly diminishes, and in about 3½ hours it is reduced to the fifth magnitude: it then begins to revive, and in the space of 3½ hours more it is restored to its original state, thus accomplishing its period in about 69 hours. The star δ Cephei has a period of about 5 days 8½ hours, and β Lyræ one of 6 days 9 hours. A star in the breast of the Swan has a period of about 15 years, during five of which it is invisible. Various other similar instances have been remarked; and the variable stars already catalogued amount to a large number.

Temporary Stars.—On examining ancient catalogues, it is found that some stars formerly distinguished by their splendour have entirely disappeared, no stars being now found in the places which they are set down as having occupied. Others have suddenly shone forth with extraordinary brilliancy, and after a longer or shorter period have gradually died away, and become extinct. A phenomenon of this kind, about 125 years B.C., induced Hipparchus to undertake the formation of his catalogue. In the year 389 of our era a star suddenly blazed forth near α Aquilæ, and remained for three weeks as bright as Venus, and then disappeared. But one of the most remarkable instances is that of the star which appeared in 1572, and was observed by the astronomer Tycho Brahe. It suddenly shone forth in the constellation Cassiopeia, attained a splendour equal to that of Jupiter and Venus when nearest the earth, and could be seen by the naked eye at mid-day. Its brightness gradually diminished, and at the end of sixteen months it disappeared, and has never been seen since. During the time of its visibility, its

apparent place remained unchanged. All the phenomena attending it are fully described by Tycho in his work entitled *De Nova Stella Anni* 1572. A similar phenomenon occurred in the year 1604, in the constellation Serpentarius, of which an account is given by Kepler (*De Stella Nova in Pede Serpentarii*, Pragæ 1606). For various other instances of a similar kind, and also of stars set down in the catalogues, but which cannot now be found, the reader is referred to Lalande's *Astronomie*, tome i. p. 259.

There is reason to believe that the so-called new and temporary stars are nothing but variable stars viewed at the period of their greatest brilliancy. Tycho Brahe's star, discovered in 1572, has been recently paralleled by a new star which made its appearance in *Corona Borealis*. In a few days its light was reduced from the 3rd to the 9th magnitude; and the application of the spectroscope, that most powerful instrument of research of modern times, showed it with a spectrum resembling that of our sun and the other stellar bodies, but with the difference that in addition to this, a gaseous spectrum, overlying the other, as it were, seemed to indicate the existence of an atmosphere of hydrogen in a state of incandescence enveloping the star.

Double and Multiple Stars.—Many of the stars which appear to the naked eye, or telescopes of feeble power, merely as bright points, are found, when observed with high magnifying powers, to be composed of two, and some of them of three or more stars, in close juxtaposition. This appearance may arise from the circumstance of two stars being situated in nearly the same line of view; for it is evident that two stars thus placed would appear as a double star, however great the real distance between them may be. It was suggested by Galileo that the variations (if sensible) of the apparent distance between two contiguous stars would furnish a good method of determining the annual parallax; and a series of observations on double stars was undertaken by Sir William Herschel with a view to this question. The result, however, was a discovery of a very different kind; for instead of finding an alternate increase and decrease of the apparent distance between the two stars, which would be the consequence of an annual parallax, he observed in some instances a regular progressive change from year to year in one direction. By reason of the slowness of the apparent motion, a considerable interval elapsed before he was able to determine its laws; but it was explicitly announced by him in 1803 that there exist sidereal systems composed of two stars, one revolving round the other, or both about a common centre. Subsequent observations have fully confirmed this discovery; and in some instances even the ellipticity of the orbits and the periods of revolution have been determined. Some of these binary systems, as they are called, have periods of great length; but in such cases the periods, being computed from observations extending over only a small part of the orbit, and liable besides to considerable uncertainty, cannot be held to be determined with much precision. Thus, the period of Castor has been computed by Sir J. Herschel to be 252 years, and by Mr. Hind to be 632 years. A period of 629 years was assigned to γ Virginis, but Sir J. Herschel has found that the observations are better represented by an orbit in which the time of revolution is 182 years. The period of 61 Cygni is supposed to be about 500 years. There are others, however, having much shorter periods, and which have already been observed through their entire orbits. The star η Coronæ, for example, has a period of little more than 43 years, and has consequently completed nearly two revolutions since its discovery as a double star by Sir William Herschel in 1761. ζ Ursa Majoris has a period of about 58¼ years, and 70 Ophiuchi one of about 80 years. Since the time of Sir William Herschel the observations of double stars has been a subject of much interest in astronomy, and catalogues containing some thousands of them have been published, giving the apparent distances of the two bodies, and their angles of position, or the direction of the straight line which joins them, by comparing which with future observations their orbits and periods will become known. (Herschel and South, *Phil. Trans.* 1826; Herschel, *Memoirs of the Royal Astronomical Society*, vol. iii.; Struve, *Catalogus Stellarum Duplicium et Multiplicium*, Petropoli 1837; Herschel, *Outlines of Astronomy*, 1864.)

Some of the binary systems afford curious instances of contrasted colours, the colour of the smaller star being frequently complementary to that of the larger. In such instances the larger star is usually of a ruddy or orange hue, and the smaller one blue or green. Sir J. Herschel thinks it probable that the colour of the small star is the effect of the brighter light of the large one; for it is a general law of optics that when the retina is under the excitement of any bright-coloured light, feebler lights for the time appear coloured with the complementary tints. This opinion seems strengthened by the fact that though insulated stars of a red colour, almost as deep as that of blood, appear in many parts of the heavens, no green or blue star (of any decided hue) has been noticed unassociated with a companion brighter than itself; but, on the other hand, several instances are known in which a blue or green star retains its colour in an undiminished degree when its more brilliant neighbour is concealed from the field of view of the telescope. The application of the spectroscope has further taught us that absorption varies very largely in these bodies.

On this account the celestial scenery in the various multiple systems composed of coloured stars must be of the most gorgeous description. In an extremely remarkable group, situated in the Southern Cross, near the star Kappa, among the principal stars two are red and ruddy, one is of a greenish blue, two are

green, and three others are of a pale green. 'The stars which compose it, seen in a telescope of diameter large enough to enable the colours to be distinguished, have the effect,' says Herschel, 'of a casket of variously coloured precious stones.'

Sir John Herschel remarks on this subject: 'It may be easier suggested in words than conceived in imagination what variety of illumination *two suns*—a red and a green, or a yellow and a blue one—must afford a planet circulating round either; and what charming contrasts and "grateful vicissitudes"—a red and a green day, for instance, alternating with a white one and with darkness—might arise from the presence or absence of one or other, or both, above the horizon.'

For the structure of the sidereal universe of which our sun forms a part, the reader is referred to the article GALAXY.

Star Anise. The fruit of *Illicium anisatum*, an evergreen growing in Japan and Cochin China. The seeds have the odour of common anise, and yield, when distilled with water, an oil sometimes called *Oleum badiani*, which is used by liqueur makers.

Star of Bethlehem. The popular name for *Ornithogalum umbellatum*.

Star Chamber, Court of (Curia Cameræ Stellatæ; from the ornaments of the ceiling of the room in which at one period it sate). This court was originally the privy council itself, 'sitting in the Star Chamber,' and there exercising important criminal jurisdiction, and administering equitable relief. It is mentioned as early as the reign of Edward III. In the third year of Henry VII. an Act was passed giving to the Court of Star Chamber determinate criminal powers, extending chiefly to state offences and misdemeanours of a public kind. The judges were four high officers of state, with power to add to their number a bishop and a temporal lord of the council, and two justices of the courts of Westminster. They proceeded by bill and information without the assistance of a jury. The sittings of the privy council itself, as a criminal court, were after this gradually abandoned, and its powers transferred to the Star Chamber. This court continued to exercise very extensive jurisdiction, both in political matters and in private concerns, during the reigns of Henry VIII. and his successors, until it was finally dissolved by 16 Ch. I. c. 10, together with what remained of its cognate jurisdictions. [COUNCIL, PRIVY.]

Star Fort. A fort with several salient angles, in shape something like a star. [FORTIFICATION.]

Star of India. An order of knighthood instituted by Queen Victoria in 1861, for the purpose of rendering honour to conspicuous loyalty and merit in the princes, chiefs, and people of her Indian empire. It consists of the sovereign, a grand master (who is always to be the governor-general of India), and twenty-five knights, with such honorary knights as the crown may appoint, the knights to include military, naval, and civil officers, and natives of India. The insignia of the order are, a collar, investment badge, and star, with the motto, 'Heaven's Light our Guide.' (Boutell's *Heraldry*.)

Starboard. The right-hand side of a ship, looking forwards.

Starch (akin to stark, *stiff* or *strong*). Starch is one of the commonest proximate principles of vegetables. It is characterised by its insipidity, and by insolubility in cold water, in alcohol, and in ether. It dissolves in, or at least forms a gelatinous compound with, water heated to 175°; and this solution, even when much diluted, is rendered blue by iodine. This admirable test of the presence of starch is not effective in hot solutions; and by boiling the blue colour disappears, but returns in strong solutions as they cool. The term *starch* is commercially applied to that obtained from wheat, which for this manufacture is ground and diffused through vats of water, where it undergoes a slight fermentation, and acquires a peculiar sour smell. A part of the gluten and albumen of the grain is thus separated in the form of a viscid scum. The starch, being in the form of a finely divided white powder, is gradually further separated by washing in large quantities of water, from which it is ultimately allowed to settle, and put into wicker baskets lined with linen to drain. It is then cut into squares, which are dried first in airy chambers upon porous bricks, and afterwards rolled up in papers and *stove* dried. In this latter operation the starch acquires that peculiar columnar texture and fracture which is well exhibited in opening a paper parcel as it comes from the stove. A little *smalt* is generally added to the starch, by which it acquires a very pale blue tint, and is better adapted to conceal or cover the yellow tint acquired by worn linen. Starch may be obtained from many other grains, and from potatoes and several other esculent vegetables. *Arrowroot* is the starch of the *Maranta arundinacea*; *sago*, of the *Sagus farinifera*, an East Indian palm-tree; and *tapioca* and *cassava* of the *Manihot utilissima*. Viewed under the microscope, the varieties of starch exhibit a more or less distinct globular appearance, and are said to be made up of little spherical particles of soluble starch, enveloped in an insoluble membrane, which protects the interior from the action of cold water, but which is broken or burst by hot water. In the progress of germination, and by various chemical agents, starch may be converted into gummy and saccharine matters. [DEXTRINE; DIASTASE; GLUCOSE.]

Starkey's Soap. A compound of turpentine, or oil of turpentine, and alkali.

Starling. A small social species of the conirostral tribe of perching birds (*Insessores*), allied to the crows. Our common starling (*Sturnus vulgaris*, Linn.) is mainly insectivorous, collects in large flocks in autumn, is readily tamed, and taught to warble and imitate human speech.

Starost. A title under the Polish republic enjoyed by noblemen who were in possession of certain castles and domains called *starosties*. These were grants of the crown, and conferred only for life, but generally renewed after the demise of a possessor to his heirs.

Starstone. A variety of sapphire, which, when cut and viewed in a direction perpendicular to the axis, presents a peculiar reflection of light in the form of a star. It is found in Ceylon, and is usually cut *en cabochon*, or in a hemispherical form. It is the Asteria of Pliny and the ancients.

Starting Gear of an Engine. The mechanism by which the motion of an engine is begun, and which is of a very different kind in different classes of engines. Many large engines are provided with a small steam engine to start them, and some are provided with starting valves. In every species of starting gear, the indication to be fulfilled is to enable the steam to press upon one side of the piston, while the other side is open to the atmosphere or condenser. [STEAM ENGINE.]

State Rights. The various *plantations* or settlements which were ultimately consolidated into the American Union, in 1782, or which were afterwards added to it by conquest, purchase, or occupation, had at the outbreak of the War of Independence, or as from time to time they were made to form part of the Union, a great variety of laws and constitutions, not a few discrepant political and commercial interests, and very well marked social differences. The harmonising of these laws, interests, and differences, was part of the work of those who first established the Union; a work which required infinite tact, sagacity, patience, and perseverance. For instance, so slight (in the opinion of those who formed the federal constitution) was the bond which was to form the basis of the political and diplomatic unity between the different states, that Franklin concealed his discovery of the Gulf Stream till some years after the acknowledgment of American independence, lest the possible diversion of European trade from Charlestown to New York might render the inhabitants of Carolina disaffected towards the national cause. Thus, again, although before the commencement of the War of Independence the Quakers of Pennsylvania had determined on excommunicating all members of the Society of Friends who kept slaves in their possession, and although Wesley had denounced slavery in the American plantations as 'the sum of human villanies,' and had called into existence among his followers a strong abolition party, slavery was permitted as a state institution, to be maintained or annulled according to the pleasure of the local legislature. On the other hand, the slaveholding states, in order to effect a compromise, were obliged in turn to accede to the protectionist theories of the North, and to copy the republican principles of equality which were far from the practice and habits of the early planters of Virginia and the Carolinas.

The Act of Independence declared the Union to be one and indivisible, while it recognised the internal legislation and self-government of the several states. Thus, for instance, all tariffs from which customs duties were to be collected, the right of declaring peace and war, the election of the chief officers of state, the management of the public debt, the occupation of forts and arsenals, the administration of the army and navy, the supervision of harbours and lighthouses, remained in the hands of the federal government, and of the congress and senate assembled in Washington (i.e. the legislative and political capital of the Union), a city which, with the district of Columbia surrounding it, formed, as it were, a sort of administrative metropolis.

On the other hand, the internal organisation of the several states was left to the conduct of the local legislatures. These states had each its parliament or congress and its governor. These parliaments could impose taxes, to be applied solely to state purposes; could legislate on a variety of subjects, such as the tenure of land, the right of succession, marriage, and divorce, religious and educational endowments, the social status of the various persons who formed the electoral body; could borrow money for roads and canals; and, whether small or great, contributed an equal number of representatives to the senate.

In time of peace, and when the Union was not burdened by debt, the functions of the congress and senate were comparatively unimportant. The executive was almost entirely in the hands of the president and his cabinet. The ministers do not, as in England, depend on the good will of parliament, but are nominated and retained in office solely at the will of the president. Hence the congress and senate (though they had together important powers) were, in effect, more a debating club than a legislature, and exercised but little influence on the foreign policy or the public law of the states; and conversely, the local legislature in the several states occupied a very important position, and was becoming increasingly independent of the central authority.

The divergence of interests, economical and social, which characterised the northern and southern portions of the Union, and the jealousies constantly developed from such a divergence, continually threatened a rupture between political parties, and with it a dislocation of the Union. The several states were constantly disposed to treat the authority of the Washington government and parliament with contempt, and, under the name of *nullification*, to render themselves all but independent of the central authority. There cannot, indeed, be a doubt that the Union was at first voluntary, and that there was, from the excessive devotion of the people to what were called in very early time state rights, no slight colour in the assertion, that the sepa-

ration between the two sections of the Union, which was often threatened, was the inherent right of all the states which had formed the original pact. It might, of course, be objected, that such a theory would justify a still further subdivision; that all social contracts are in their beginning voluntary, or at least are admitted so to be in a republic; but that the developement of this principle would be the dissolution of society altogether. It might further be urged, that the federal constitution proclaimed the Union to be indissoluble, and that it by no means follows that nations who are dissatisfied with the results of a voluntary act, can quit themselves of the obligation, any more than a private person can disclaim a formal and legally executed deed.

The administration of the states was by no means faultless. This was shown strikingly in the various acts of repudiation committed by many of the wealthiest states. Ten of these repudiated obligations incurred to state creditors, most of these debts having been contracted for manifest, and on the whole enduring, public benefits. The forcible appeal of Sydney Smith to the congress of Washington is well known. But the temptation to repudiation was very strong. States, like individuals, need that their conscience should be stimulated by the risk of discovery and punishment; and in general, communities having diplomatic relations with other countries find it necessary to be honest, in order that they may have any place in the world's markets. The several states of the Union, however, were under no such control; they stood in no diplomatic relation to any but the Washington government.

The doctrine of state rights culminated in secession. It is well known that opinions were strongly divided in Europe, and even in the United States, as to the justification of this act. It should be noted, however, that immediately on the commencement of the civil war, the question was distinctly settled, and the maintenance of the Union, at any risk, loss, or cost, became, for very obvious reasons, a passion among the great mass of the American people. The success of secession, to the mind of most American statesmen, implied the maintenance of vast standing armies, and ultimately of political retrogression. Any sacrifice, it was felt, was trivial compared with the enormous evils of maintaining an imaginary frontier extending for thousands of miles, and separating by no natural barriers two states, or two aggregates of states, whose disunited interests were and would be intensely irreconcilable. At present (1866), the contest, happily only political, which is raging in the United States, bears testimony to the tenacity with which the several communities composing the Union cling to the right of domestic legislation, even when the exercise of this right would imperil all the results of the war, by stereotyping distinctions of race.

It can scarcely be doubted that state rights, in so far as they are aggressive, or antagonistic to the general interests of the American people, will be modified. The memory of past sacrifices, losses, expenses, and debts, will effect much; the increasing importance of congress will effect far more. At present, congress has on its hands the management of an enormous debt. The charges of this debt, in part met by direct taxation, are in great measure liquidated by customs and excise duties; the former being, in accordance with the protectionist theory, to which recent events have given temporary strength, by far the most onerous and inconvenient to the mass of the community. But no one can doubt that before long protection will be assailed in congress, and that this body, whose functions have up to the war been comparatively unimportant, will have to devote much attention to these national questions, and will become a field for the exercise of great financial and political skill. In such a case the local legislatures will occupy a very inferior position.

Stater (Gr. στατήρ). An ancient Greek measure of value. It was undoubtedly a coined piece of money at an early period. The common gold currency in the republican times of Greece consisted of staters. The Attic golden stater weighed two drachms, and is estimated at twenty silver drachms; but the value of the coin struck by different states with this denomination varied greatly.

States or **Estates** (Fr. états, Ger. stände). In modern European History, those divisions of society, professions, or classes of men, which have partaken, either directly or by representation, in the government of their country. Their number has varied in different countries. In France, and most other feudal kingdoms, there have been three estates (nobles, clergy, commonalty), members of the ancient national assemblies. Hence the well-known appellation *tiers état* (third estate) for the last. In Sweden there are at this day four: nobility, clergy, citizens, peasants. In most countries the ancient system of assemblies convoked from separate estates disappeared by the progress of absolute government in the sixteenth and seventeenth centuries; and in modern monarchical constitutions the English system of government, by king, lords, and commons, or analogous powers, has for the most part prevailed.

States-General. In French History, assemblies which were first called A.D. 1302, and were held occasionally from that period to the year 1614, when they were discontinued, till they were summoned again in the year 1789. These states-general, however, were very different from the ancient assemblies of the French nation under the kings of the first and second race. (Hallam's *Middle Ages*, ch. ii. part ii.) There is no point with respect to which the French antiquaries are more generally agreed than in maintaining that the states-general had no suffrage in the passing of laws, and possessed no proper jurisdiction. The whole tenor of French history confirms this opinion. [ASSEMBLY; DIRECTORY.]

Statics (Gr. ἡ στατική, sc. ἐπιστήμη, *the*

science of weight). The branch of Mechanics which has for its object the investigation of the conditions of equilibrating forces, or the conditions under which several forces applied to a rigid body mutually destroy each other.

There are three general principles on which the theory of equilibrium may be grounded; these are: 1. The principle of the lever; 2. The principle of the composition of forces; and 3. The principle of virtual velocities.

Principle of the Lever.—The equilibrium of a straight horizontal lever, loaded at its extremities with weights which are reciprocally proportioned to their distances from the fulcrum, was demonstrated by Archimedes [LEVER]; and it is easy to extend this principle to the bent lever, when the fulcrum is at the angular point, and to show that if the two arms be urged in opposite directions by two forces perpendicular to the arms and reciprocally proportioned to their lengths, there will be equilibrium. Now, it is an axiom in statics that a force may be regarded as acting at any point whatever in the line of its direction; and hence it follows that any two forces, applied at any points whatever in a plane which is only movable round a fixed point, and having any directions whatever in that plane, will be in equilibrium when they are to each other reciprocally as perpendiculars drawn from the fixed point to their lines of action; for the perpendiculars may be regarded as the arms of a bent lever having the fixed point for its fulcrum. This general principle, which is also called the *principle of moments*, suffices for the resolution of all the problems of statics, and is indeed the only one which was rigorously demonstrated before the discovery of the composition of forces, i. e. before the publication of the *Principia* in 1687.

Composition of Forces.—The second general principle consists in this, that any two forces acting together upon the same point of a body are equivalent to a single force represented in intensity and direction by the diagonal of a parallelogram, the sides of which represent the two given forces. This equivalent of the two forces is called their *resultant*; and as the resultant may be combined with a third force acting on the same point, and the resultant of this composition with a fourth, and so on, it follows that any number of forces applied to the same point have a single resultant, or may be replaced by a single force. [FORCE.] This principle was not known to the ancients. Galileo demonstrated that a body moved by two uniform velocities, the one vertical and the other horizontal, must acquire the velocity represented by the hypothenuse of the right-angled triangle, whose sides represent respectively the two velocities. This is a particular case of the principle. Newton proved it to be true generally, and substituted the composition of forces for that of motions; and in the second corollary to the third law of motion, he shows how the laws of equilibrium may easily be deduced from it. The *Nouvelle Mécanique* of Varignon, published in 1725, contains the first complete theory of the equilibrium of forces in different machines, deduced solely from the principle of the composition of forces. The simplicity of the principle, and the facility of its application to all questions connected with equilibrium, caused it to be almost immediately adopted; and it is the basis of all the modern treatises on statics.

Virtual Velocities.—If we conceive the body to which a system of forces is applied to be slightly displaced, and multiply each force by the velocity of its point of application, estimated in the direction of that force, *the algebraical sum of the products thus formed will vanish if the forces be in equilibrium*; and conversely, *if the sum vanish the forces will be in equilibrium*. This is the third general principle on which the conditions of equilibrium may be made to depend. It applies almost self-evidently to the conditions of equilibrium of the lever, pulley, and other simple machines. Its generality was first remarked by John Bernoulli. It has been adopted by Lagrange, as the basis of his *Mécanique Analytique*; and it has the advantage over the others of being capable of representation in a single general formula, which includes the solution of every question that can be proposed relative to the equilibrium of forces. Lagrange, however, remarks that it is not sufficiently self-evident to be erected into a primitive principle; but it may be regarded as a general expression of the laws of equilibrium deduced from the two former principles. [VIRTUAL VELOCITY.]

The general problem of statics consists, as above remarked, in the determination of the conditions of equilibrium of a body under the action of a given system of forces or pressures.

These conditions are expressed by the following *six equations of equilibrium*, which may be at once deduced from the principle of the COMPOSITION AND RESOLUTION OF FORCES AND COUPLES.

$$\Sigma P_i \cos \alpha_i = 0, \quad \Sigma P_i \cos \beta_i = 0, \quad \Sigma P_i \cos \gamma_i = 0,$$
$$\Sigma P_i (y_i \cos \gamma_i - z_i \cos \beta_i) = 0,$$
$$\Sigma P_i (z_i \cos \alpha_i - x_i \cos \gamma_i) = 0,$$
$$\Sigma P_i (x_i \cos \beta_i - y_i \cos \alpha_i) = 0.$$

Herein P_1, P_2, &c. denote the given forces, $\alpha_i, \beta_i, \gamma_i$ the direction cosines of any one of them, say P_i, with respect to any rectangular co-ordinate axes, and x_i, y_i, z_i the co-ordinates of any point in the line of action of P_i; the summation is, of course, to be extended to all values of i corresponding to the given forces. The application of these equations to special problems is explained in all treatises on mechanics. The classical work on the subject is Poinsot's *Elémens de Statique*; Möbius's *Statik* is also a most instructive work; the principal contents of both, however, are collected in every good English text-book, of which a few have been already cited in the article MECHANICS.

Station (Lat. statio). In Astronomy, a

planet is said to be at its *station*, or to be *stationary*, when its motion in right ascension ceases, or its apparent place in the ecliptic remains for a few days unaltered. The real motions of the planets are always in the same direction from west to east; but owing to the motion of the earth from which they are seen, their *apparent* motions, though generally from west to east, or direct, are sometimes from east to west, or retrograde, and in changing from one of these directions to the other the planet appears for some short time to stand still. The distance of the earth and of a planet from the sun being given, and also their periodic times, the determination of the arc of retrogradation, or the times at which the planet will appear stationary, is an easy problem; but to the ancient astronomers, who were unacquainted with the relative distances of the planets, and who, moreover, supposed the earth to be the centre of motion, the phenomena of the stations and retrogradations occasioned great embarrassment, and the principal object of the various systems which were propounded previous to that of Copernicus was to give a satisfactory explanation of them. [EPICYCLE; PLANET.]

STATION. In Shipbuilding, the same as ROOM AND SPACE.

STATION. In Surveying, the place selected for planting the instrument with which an angle is to be measured.

Station Pointer. An instrument used in maritime surveying, for expeditiously laying down on a chart the position of a place from which the angles subtended by three distant objects, whose positions are known, have been observed. It consists of three scales, which move about a common centre. Two of these carry divided circular arcs, and the third is provided with two verniers adapted to the arcs, by means of which the scales can be opened so as to form any two angles. If we suppose the angles of the scales to be made equal to the two measured angles, and the instrument to be laid on the chart, so that the edges of the three scales coincide with the positions of the observed objects, the centre will mark the position of the spot from which the objects were observed. (Simms' *Treatise on Mathematical Instruments*, p. 98.)

Stations (Lat. statio, *an outpost*). In Ecclesiastical Antiquities, the weekly fasts of Wednesdays and Fridays. These were omitted between Easter and Whitsuntide. They terminated at three in the afternoon; hence sometimes called *semijejunia*. Saturday was made a station day by the council of Elvira; and this, it is said, led to the gradual neglect of the Wednesday station in the Western church.

The term *station* is also applied to certain points in the narrative of the passage of Christ from the judgment-seat to the cross, which are selected by the Roman Church as subjects for meditation, and are well known through the pictorial representations common in Roman Catholic churches.

Stations, Railway. Buildings erected for the reception of the passengers and goods intended to be transported by railways. These stations are either terminal stations or side stations. The terminal or main stations frequently divide their business into two parts, and one portion of the station is devoted to the reception of passengers, and the other portion to the accommodation of goods; or sometimes there are two different terminal stations, one for goods and the other for passengers.

Terminal or main stations are often of great extent, and of a complex character, as, in addition to the structures required for the reception of goods and passengers, carriage dépôts and locomotive workshops are comprehended in the general design. In such stations there must be provided booking offices, where the several classes of passengers take their tickets; waiting-rooms for the first, second, and third class; refreshment-rooms, luggage office, and various other requisite accommodations. Generally, too, the chief offices of the railway company, with proper apartments for the secretary and clerks, and a board room for the directors, are situated at the principal terminal station of a railway. There are also platforms both for the arriving and departing trains, and platforms for loading and unloading luggage, with proper hoisting gear driven by steam. There are also lamp rooms and rooms for the accommodation of the attendant porters; and there is always a system of turn-tables, or other analogous arrangements, for transferring the engines and carriages from one line to the other.

The most remarkable feature of railway stations is the roof, which covers the platforms where the trains are received and despatched, the area covered being often very great, and the roofs being sometimes of very large span. These roofs are generally formed with wrought iron ribs or rafters properly trussed, but sometimes they are made of timber. In the new station at St. Pancras, designed by Mr. Barlow for the Midland Railway, the area covered is 690 feet by 240 feet. The main ribs are 29 feet 4 inches from centre to centre, with three intermediate ribs at equal distances between them, carried at every 18 feet 6 inches by trussed purlins between the main ribs. The ribs spring directly from the ground, and are firmly connected to massive brick piers below the floor level. The curve of the ribs is formed with two radii of 160 feet and 57 feet meeting in an angle at the centre 100 feet above the level of the rails. The ribs are 6 feet deep, and are formed with open box flanges 10½ inches deep, the flanges being braced together by diagonal channel iron, and radial struts forming the purlins. The purlins are braced beams, so constructed as to stiffen the main ribs laterally. The whole of the roof is braced horizontally, to resist any strain that may be caused by the pressure of the wind either on the gable or on the side. The apex of the roof is covered with glass ridge and

furrow skylight, 152 feet wide, extending nearly the entire length of the roof, and each gutter of the skylight has a snow grating along its whole length, with cross strips to enable the workmen to repair and paint the skylight, when required. The part of the roof below the skylight is covered with boarding and slates. To take off the thrust of the ribs, they are connected across below the rails by wrought-iron beams resting on pillars. The weight of iron in this roof is about 1,100 tons. The roof of the Great Northern Railway station is formed with a circular plank arch on Colonel Emy's plan. [ROOF.] That of the Charing Cross station is also circular, but iron of 180 feet span. The roof of the Lime Street station at Liverpool is of iron of 152 feet span, and that of the station at Birmingham is 864 feet long, and at one end 212 feet span, the width at the other end being slightly less. The Broad Street station of the North London Railway is one of the most successful examples of stations in this country. In roofs constructed with trussed principals, provision is usually made to allow of the expansion of the metal. But in arched roofs this is not so necessary, although rollers, or other expedients for permitting expansion, are usually introduced.

In the Cannon Street station of the Metropolitan District Railway, designed by Mr. Hawkshaw, the total length is 675 feet, and the breadth 201 feet 8 inches, covered by an arched roof of a single span. There are 20 trussed principals, placed 33 feet 6 inches apart, except where the station crosses Thames Street, where they are 35 feet apart. The clear span between the bed plates on the opposite walls is 190 feet 4½ inches. The height from the rails to the springing is 46 feet; from springing to upper side of rib 60 feet; and from upper side of rib to ridge of central skylight 9 feet; making a total height of 115 feet. Each principal is 1 foot 9 inches deep, and 1 foot 2 inches across the bottom flanges. The web is ⅜ thick, and the connecting angle irons are 3 inches by 3 inches by ½ inch. The rib is curved with a radius of 108 feet ⅞ inch, which gives a versed sine of 60 feet. It is trussed at eight points, with vertical struts tied together at the bottom, and braced diagonally. The struts are made of two wrought-iron plates, 10 inches by ½ inch each, stiffened on the outside by T irons 6 inches by 3 inches by ½ inch, and kept asunder by cast-iron distance pieces. The diagonal bracing consists of flat bars 6 inches by ¾ inch at the centre, and 6 inches by 1 inch at the springing. The ends of the main ribs rest on cast-iron bed plates, one bearing being fixed and the other moving on rollers, so as to permit expansion and contraction, and thus take all strain off the walls. For a width of 10 inches from each end, the rib is made double, and the intermediate space is filled with a casting, which stiffens the rib and gives greater area of bearing surface. Wrought-iron purlins 1 foot 8 inches deep, with upper and lower flanges, formed of angle iron 5 inches by 3 inches by ½ inch, extend along the whole length of the roof, at intervals of 11 feet. Louvres on each side of the skylight provide for ventilation. The roof for 22 feet on each side of the louvre frames is formed of corrugated zinc sheets, laid on plank 1½ inches thick, below which for about 50 feet the roof is of glass, and below that it is covered with slates. The length of the longest vertical strut in the roof is about 27 feet, and of the shortest about 15 feet.

It would exceed the limits of this article to enter into any description of the railway workshops commonly introduced at important terminal stations. But it may be stated generally that the circular form of workshops at one time employed has now been abandoned, and the workshops for the repair and construction of locomotives are now very much like common engine factories. In the Crewe workshops great improvements have been introduced by Mr. Ramsbottom, together with many new machines, among which may be enumerated the rolling mill for rolling the tires of railway wheels out of a perforated disc without a seam, and the duplex steam hammer, in which two hammers are made to move simultaneously in a horizontal plane, so that the mass of iron on the anvil is struck by a hammer on each side at the same time. Most of the woodwork of railway carriages is now made by proper shaping machines to the form required. No good arrangement of sheds has yet been introduced for keeping engines under when the steam is up, and the smoke emitted from the engines rapidly corrodes the iron work of the roof in which such engines are usually placed, while the smoke vomited forth from the doors and other apertures near the ground constitutes a nuisance to the neighbourhood. For getting the steam up in locomotives and for keeping it up, swivelling pipes of sheet iron, like water cranes, should be set at convenient distances apart on each line of rails, which pipes should communicate with a great flue running beneath the floor of the shed from end to end, and communicating with a chimney, in which the velocity of the current of smoke might be maintained by the introduction of a steam jet. Each engine when the fire was kindled would have the swivelling pipe brought over the funnel, so as to take the smoke and transmit it to the great chimney, by which it would be conducted high into the atmosphere, and there dispersed. In some cases the locomotive running sheds, instead of being rectangular, are fan-shaped and sometimes semicircular, with a turn-table for directing the engine upon any one of the radiating lines, but the turn-table is not usually covered. With this arrangement any injury to the turn-table locks all the engines up.

The arrangement of the booking offices in a railway station is an object of considerable importance where a large passenger traffic has to be conducted. Two plans are in common use. In one the offices are set upon the departure platforms, and in the other they are

placed across the ends of the platforms at right angles to the lines of rail. At the Victoria station in Pimlico both plans are in use, the former being adopted for the London, Chatham, and Dover, and the latter for the Brighton traffic. Goods stations should be so placed as to be easily accessible from the neighbouring high roads, and should be so arranged that the goods trains may be run into them direct without uncoupling. The mineral and general goods traffic should be kept distinct, and goods yards should be placed upon a level, and arrangements for shunting without the use of engines should be provided. At the Camden station small capstans driven by shafting are erected at suitable points, and by passing a rope round one of these revolving capstans a train may be moved in any required direction. Hydraulic machinery, for hoists and otherwise, is employed at some stations with satisfactory results. The Great Northern goods shed, which is nearly in the centre of the yard, covers fourteen lines of rails.

Suspension roofs for large spans were advocated by Mr. Hansom about 1840, and more recently by MM. Lehaître and de Mouldésir in a paper read before the Society of Civil Engineers of France in 1866. They estimate that a roof of this character for a circus 100 mètres or 328 feet in diameter with a central column of cast iron, and the covering of zinc No. 14 wire gauge, would not exceed 3*l*. 6*s*. 8*d*. per square yard, or without the central column 3*l*. 2*s*. 6*d*. For rectangular buildings it is proposed to carry the chains by columns placed upon the side bearing walls, those parts of the rafters which are nearest the sides being slung from the chains, while the central portions are supported by struts. The suspension may be effected by steel wire ropes.

Stationary Contact. The curve of intersection of two surfaces which touch each other has in general a double point at the point of contact, the tangents at which are distinct. When these tangents coincide, there is a cusp or stationary point on the curve of intersection, and the contact of the surfaces is then said to be *stationary*. (Salmon's *Analytical Geometry of Three Dimensions*, Dublin 1862.)

Stationary Engine. A form of steam engine for drawing carriages on railways by means of a rope, so called to distinguish it from the locomotive engine, which runs along the railway, drawing the carriages after it. Railway propulsion by means of stationary engines placed along the line for the purpose of drawing the carriages from stage to stage, was at one time contemplated as an alternative system to locomotive propulsion. But the improvements carried out about 1830 in the locomotive removed the chief inducements to the adoption of stationary engines, which are not now employed except as an expedient for enabling a train to ascend very steep inclines. The Ghauts in India, the Sœmmering Alps, and many other mountainous ascents up which railways have been carried, are surmounted by powerful locomotives; and a locomotive has been enabled to pass over Mont Cenis, by constructing the line with a high central rail, the opposite sides of which are bitten by friction wheels driven by the engine. But the railway recently carried over a part of the Andes to Santiago makes use of stationary engines, which draw up the train from stage to stage by ropes. Such ropes should be made of steel wire, and should have numerous swivels in their length to obviate the risk of kinks. There is nothing peculiar in the stationary engine employed for this purpose.

Stationary Point. If a plane curve be conceived to be generated by the motion of a point in a line (the tangent) which itself turns around that point, then a stationary point on the curve will be produced whenever the describing point comes to rest momentarily, previous to changing the direction of its motion in the tangent. A stationary point is sometimes called a *cusp*. It may also be regarded as a *double point* at which the two tangents to the curve coincide. The tangent at a stationary point, therefore, meets the curve in three coincident points; it is termed a *cuspidal tangent*.

Stationary State. A phrase employed by some economists to denote that condition of society which neither progresses nor retrogrades, and in which the accumulation of capital only keeps pace with its destruction or consumption. Such a condition is of course hypothetical; but the expression is intended to indicate that when the rate of profit is low, the disposition to accumulate is weakened; when the rate is high, saving is encouraged. These facts will, however, be exhibited concurrently with the disposition of a community, provided the advance of capital is secured to the lender; for it may be the case that rates of profit are high, while the disposition to accumulate may be neutralised by indifference or by insecurity, or the rate of profit may be very low, while the instincts of the people lead them to economy. The last case may be illustrated by the low rate of profit and the saving habits of the Dutch in the last century.

Stationary Tangent of a Curve. A double tangent at which the points of contact coincide. It meets the curve, therefore, in three consecutive points. The curve being regarded as the envelope of a movable line, the latter will be a stationary tangent whenever, previous to its rotation being reversed, its motion is momentarily arrested. The point of contact of a stationary tangent is called a *point of inflexion*, since the curve there passes from one to the other side of the tangent. The points of inflexion of a curve (together with its double points) all lie on its Hessian.

Stationary Tangent Plane of a Surface. A tangent plane which has stationary contact with the surface. Such a plane may be regarded as a double tangent plane whose points of contact coincide. The point of contact of a stationary tangent plane is called

a *parabolic point*. [INDICATRIX; PARABOLIC POINT.]

Through any point in space there can in general be drawn $4n(n-1)(n-2)$ stationary tangent planes. (Salmon's *Analytical Geometry of Three Dimensions*.)

Stationery. The name given to all the materials employed in the art of writing, but more especially to pens, ink, and paper. The term *stationery* is derived from the business of booksellers having been anciently carried on entirely in stalls, or *stations*. The Stationery Office in London is the medium through which all government offices, both at home and abroad, are supplied with writing materials; and at the same time it contracts for the printing of all reports and other matters laid before the House of Commons, &c. It consists of a comptroller, a storekeeper, and about thirty clerks and other subordinate officers, and has a branch establishment at Dublin.

Statistics. This modern term, which has finally superseded its ancient equivalent *political arithmetic*, is held to include all collections of facts which bear upon social life, and such inferences from these facts as rest on numerical calculations, in special contrast to those which are derived from a real or supposed analysis of the moral nature, or the sympathies, the antipathies, the reason, and the feelings of mankind. The fundamental law in such inferences is, that in particular domains of enquiry comprising these social phenomena, the uncertainty which attaches itself to all induction on the individual action of mankind, and their individual tendencies and liabilities, is eliminated when an aggregate is taken. Thus, for instance, we cannot state certainly that any particular individual will apply himself to the satisfaction of any economical demand, but we may be quite certain that, in a general estimate of society, parties will be found who will engage themselves in such occupations; we cannot assert that any particular individual will die of disease in a given number of years, but we may be certain, if a sufficiently wide basis for inference be taken, and all the facts which might disturb the average be accounted for, that a given number of lives will fall annually out of a thousand inhabitants of all ages, and so on. The essential feature, then, of all statistical inductions is that they are derived from averages, and the necessary caution in all such averages is that they are at the best approximations to physical certainty, for every statistical product is always guarded by a margin of variation. If it were possible to analyse completely the physical, mental, and moral constitution of man, we might be able to deal with individual men as accurately as we can determine the constitution and predict the phenomena of inorganic bodies. But at present organic existence, and in particular those forms of organic existence which are endowed with spontaneity, are not so susceptible of such a scientific analysis as would result in a scientific induction. Statistical methods of inference, therefore, are strictly relative to such phenomena as defy exact analysis, and are provisional, or at least imperfect.

Similarly, statistical enquiry is directed to such physical phenomena as, being relative to man's several instincts and interests, are not yet collected within the verge of exact analysis. For instance, the course of the seasons, and in particular their effects on the supply of food, are matters of most interesting statistical enquiry. The utmost powers which meteorological observations have conferred on mankind in variable climates seem to be the capacity for a somewhat vague prediction as to what the weather will be for the next twenty-four hours, and this in particular when considerable atmospheric changes are imminent. There has yet been no approximation even of the rudest kind to the discovery of a cycle of the seasons. We have not the least means of guessing, with even a shadow of precision, in the month of January what will be the weather in August. But as the gross amount of corn grown on the soil is relative to the amount and distribution of direct solar heat and moisture in the three summer months, and the amount of corn grown has an immediate effect on prices, and an indirect effect on the relations in which this country stands to foreign corn-producing regions, evidence as to the annual crop, and averages over a series of years, are of considerable importance to the trade and resources of a community, and are said to be statistical. A similar obscurity attends any attempt to determine precisely the constitution of the atmosphere, and its freedom from or impregnation by those mysterious molecules by which endemic, epidemic, and sporadic diseases are generated and perpetuated. But statistical enquiry during the local and general prevalence of such phenomena is exceedingly important, generally highly suggestive, and occasionally susceptible of being put into the shape of a rule. Logically, then, the inference of the statistician is the calculus of probability, in which the probability is heightened by the width of the area, and the plurality of the instances or examples from which the inference is attempted.

The earliest statistical calculations—apart from some vague and uncertain guesses as to the currency and population—were made for certain practical purposes, for the granting annuities and effecting insurances, i.e. the first statistics were what is called *vital statistics*. Such calculations illustrate better than anything else the nature of a statistical induction. No one would ever venture to insure only one life at a vast sum, or grant one annuity only, the payment of which would occupy the whole income of the individual or company making the grant. A number—the largest number possible—of small or comparatively small insurances or annuities are negotiated and effected, in order that the element of risk may be eliminated as much as possible. The ordinary duration of human life, as calculated from enquiries, is not, however, adopted in either case; a margin is always left wherewith

to cover risks and avoid such exceptional circumstances as might disturb the probability. But even with this margin, no small nicety is required in making the calculation. In the early days of the actuary's craft, the duration of human life was considerably underrated. As a consequence, a loss was generally incurred on annuities, a gain on insurances.

Physical laws are very seldom developed from statistics, but they are occasionally suggested by them. An excellent illustration of this distinction is to be found in the laws which govern prices. In the very early days of statistical enquiry, Gregory King came to the conclusion that a scarcity in any commodity for which there is a great and permanent demand, raised the price of what was at hand to satisfy demand to a far greater height than the whole quantity would have reached had the demand and supply been in equilibrio. Thus, for instance, if 20 million quarters of wheat are needed as food for a nation, and the price when in equilibrio is 50*s.* the quarter, a scarcity of ten per cent. will not raise the remaining 18 millions to the price of the 20, i.e. to 50 million pounds, but to 60 or more. Here we have a law, depending upon the urgency of a demand for the necessaries of life, suggested no doubt in the first instance by statistical data, but depending on certain facts in the moral and physical nature of man.

Statistical influences are exceedingly liable to fallacy. This contingency is embodied in the cynical maxim that 'there is only one thing falser than facts, that is figures.' Fallacies in statistics, real and apparent, arise from several causes. In the first place, there is, as Bacon observes, an eager tendency of the human mind towards generalities (gestit mens humana exsilire ad magis generalia), and nowhere so constantly as on social and political phenomena. Concurrent with this tendency, if not identical with it, is that of referring phenomena to simple causes when, in fact, they are the products of a complex causation. A dominant cause, or even a dominant point of view, is taken to explain and account for all the facts. But the chief risk which statistical inferences run, is that of admission as to their scientific, or quasi-scientific sufficiency, but of resistance on the ground that qualifying circumstances, or inveterate and repugnant habits, or compensating forces render it necessary that they should be postponed, modified, or disclaimed. No fuller statistical proof could have been given of any rule, than that in vindication of free trade in corn; it was resisted, not from hesitation as to its abstract truth, but because it was averred that the state of society was artificial, one in which existing interests, originally perhaps indefensible, but now vested, had to be maintained, and in which political and social expediency should override economical laws.

Much discredit has fallen on statistics in consequence of the extravagant and undue exaltation which, in the hands of some persons, has been accorded to certain averages. Thus, the attempt to discover a physical law in the annual proportion of suicides is, it can scarcely be doubted, an absurd and illogical dream, an induction as unreal as those ancient acts of simple enumeration which Bacon exposed. The world, so far as has yet been discovered, is not governed or constituted by these numerical quantities, which are at the best fractions more or less precise and determinate, indicating tendencies which, if they were traced or traceable, would forthwith drop the guise of a numerical quantity, because in all natural laws number goes for nothing, one instance being equal in value to a thousand. In general, too, we may apply the canon of utility to all statistical enquiries. Those calculations which tend neither to direct nor to remedial action are merely curious speculations.

Some statistical inferences are of the highest practical value, as, for instance, those which are called *sanitary*. It has been found, for example, that, under ordinary conditions of health, the annual rate of mortality is about seventeen in the thousand. Any considerable excess over this number suggests that there is something wrong, while any slight deficiency indicates the materials for a contrast. So absolute and yet so practical is the rule derived from this simple numerical statement, that it is not too much to ascribe to it all those improvements in lighting, airing, and draining dwelling-houses, which have so characterised the civilisation, and improved the condition of the people in our times. Similar, and not much less important, is the connection which has been traced between high prices of food and pauperism, crime, and bastardy. The co-ordinate rise and fall of averages such as these, though not absolutely conclusive, are very important aids to that inductive method which Bacon called the rule of *travelling instances*, and Mr. Mill has represented under the term of *concomitant variations*. [LOGIC.]

Statistics in foreign countries are generally supplied from the various administrative bureaux, and are, as a rule, exact and exhaustive. In England the collection of statistics is partly the function of government boards (and as far as these can enquire are as good as can be), and, in part, the action of individual observation or research. Thus the customs returns of exports and imports, of shipping, of trade, of railways, are supplied from the Board of Trade; that of the banks and circulation, from the Treasury; that of pauperism, from the Poor Law Board, &c. But some statistics of great importance are as yet withheld, or only grudgingly accorded. Among those which are desiderated are agricultural statistics, the value of which, though overrated perhaps by some economists, has been, on the other hand, underrated by others. It has been said, for instance, that a knowledge of the breadth of corn sown would be of little interest in determining prices or the exigencies of supply, since no one from year to year can decide from such and such an average what is the yield, and still less what is the average

quality of the grain. This, indeed, may be admitted, but the value of the information if procured would yet be great.

As we have stated, the value of statistics consists not so much in their announcing facts, as in their supplying the premisses for calculating an average. But information as to the amount of corn sown, or breadth of arable land in given years, has this value, that it determines the proportion of home growth to the need of foreign importation, and, within certain limits, suggests the extent of the demand for foreign supply. Much more striking, however, is the significance of the evidence which has recently been given as to the amount of cattle, sheep, and pigs kept in England and Wales, and the immediate explanation which this evidence supplies as to the high price of meat. Of almost all countries, England has the lowest amount of animals used for food in proportion to population.

Within the last thirty years, the collection and arrangement of statistics has formed the business of a very important society in London, and of similar societies elsewhere. The Statistical Society of London has made a most important collection of facts bearing upon every branch of social science, and has regularly tabulated the most important objects of trade and finance. Much of the political economy of foreign countries is in effect statistical in character, and has been supported and furthered by government. An exceedingly important international congress is held triennially in some one of the European capitals, the origin of which was suggested by M. Quetelet of Brussels, in which city the first congress was held. The meeting in London (1860) divided statistical research into six sections: judicial, sanitary, industrial, commercial, census, with military and naval statistics; and, lastly, statistical methods and signs. See the report for the fourth session of the International Statistical Congress, and in particular the excellent introduction by Dr. Farr, and the speech of the late Prince Consort; also *Lettres sur la Théorie des Probabilités appliquée aux Sciences Morales et Politiques*, par A. Quetelet.

Statuary. [SCULPTURE.]

Statue (Lat. statua). In Sculpture, a representation in relief in some solid substance—as marble or bronze—or in some apparently solid substance, of a man or other animal. There are various species of statues: 1. Those smaller than nature, or *statuettes*. 2. Those of the same size as nature. 3. Those larger than nature, called *heroic figures*. 4. Those that are several times larger than nature, and are called *colossal*. The first were by the ancients made to represent men and gods generally. The second represented men celebrated for their learning and talents, who had rendered service to the state, and were executed at the public expense. The third were confined to kings, emperors, and heroes. The fourth species consisted of statues of the gods, or of kings and emperors represented under the form of gods. *Equestrian statues* are those in which the figure is seated on a horse. The *Hermæ*, or terminal figures, were pillars surmounted by a head or a bust, according to the deity represented, though the name is derived from that of the god Hermes. Various examples of these figures may be seen in the British Museum. [CHRYSELEPHANTINE; HERMÆ; SCULPTURE.]

Status Quo (Lat.). In Politics, a treaty between two or more belligerents, which leaves each party in possession of the territories, fortresses, &c., which it occupied before hostilities broke out, is said to leave them *in statu quo ante bellum*—in the same state as before the war.

Statute (Lat. statutus, part. of statuo, *I establish*). An Act of Parliament made by the sovereign, by and with the advice of the lords and commons. But some ancient statutes are in the form of charters or ordinances, proceeding from the crown, and in these the consent of the lords and commons is not expressed.

Statutes are divided into *public* and *private*; public Acts being usually defined to be those universal rules which regard the whole community, while private Acts only operate upon particular persons and private concerns. Of private Acts, some are *local*, as affecting particular *places* only; others *personal*, as confined to particular *persons*. Formerly the courts of law were not bound to take judicial notice of a private Act unless it were specially pleaded; and to evade this rule, it became the practice to insert in private Acts a clause declaring them to be public, and binding the courts to take notice of them. It has, however, been provided by stat. 13 & 14 Vict. c. 21, that every new Act is to be taken to be a public Act, and judicially noticed as such, unless the contrary be expressly declared. There is, accordingly, a large class of railway and other *local* Acts, which, though classed with private *bills*, become, when passed, public *Acts*. In private Acts expressly declared *not* to be public Acts, a clause binding the courts to take judicial notice of them is still usually inserted. It will have been seen, however, that the division of statutes into public and private is now chiefly of a formal nature, although in parliamentary practice there are important differences in the manner of passing public and private *bills*, the latter being usually sent as of course for enquiry before a select committee, and being subjected to heavy fees and other expenses, from which the former are exempt. Statutes are also said to be *declaratory* of the law as it stood at their passing; *remedial*, to correct defects in the common law, subdivided into *enlarging* and *restraining*; and *penal*, imposing prohibitions and penalties. But these, again, are rather distinctions of an arbitrary character than of any legal effect, although some legal maxims have been founded on them: e.g. that penal statutes, or clauses in statutes, are to be construed strictly, remedial statutes liberally, &c.

The courts, however, are not, at the present

day, much influenced by general maxims of this nature, except as affording some slight aid to construction in very doubtful cases. Statutes are divided in the statute book, for convenience of reference, into *Public General Acts*, *Local and Personal Acts declared Public*, *Private Acts Printed*, *and Private Acts not Printed*. All the Acts of one session of parliament taken together are said to form properly but one statute, and for this reason an Act of Parliament is always cited as the *chapter* of a particular *statute*, e.g. stat. 29 & 30 Vict. c. 1. Statutes now operate (by stat. 33 Geo. III. c. 13) from the time when they receive the royal assent, unless some other time be fixed for that purpose: the ancient rule was that, in default of any special provision to the contrary, they operated retrospectively from the first day of the session in which they were passed. Every public general Act passed at the present time extends (in the absence of any special provision to the contrary) to the whole of Great Britain and Ireland, exclusive of the Channel Islands and the Isle of Man. With respect to the colonies, the rule is that, in a colony acquired by occupancy, Acts passed before its acquisition come into force immediately upon that event as part of the general law of England, as to all provisions at least not unsuitable to its social circumstances; though it is otherwise in the case of a colony won by conquest or cession, which remains subject to its own pre-existing laws. (1 Steph. *Comm.* 107.) No colony of either class is, in the absence of express provision or necessary implication, affected by Acts of Parliament passed after its acquisition. The sovereign is not bound by any statute, unless named therein.

The growing inconvenience caused by the confusion and multiplicity of the statutes has excited considerable attention of late years. Lord Chancellor Cranworth issued commissions in 1853 and 1854 successively, for the purpose of consolidating the statute law, but these commissions produced little practical result; and the commission of 1854, after sitting for several years, was discontinued abruptly in 1859, owing to the refusal of the House of Commons to vote any further funds for its maintenance. A considerable part of the criminal law was, however, consolidated by a series of statutes passed in 1861. (24 & 25 Vict.) Several statutes, moreover, have been passed of late years for the purpose of expurgating the statute book by the repeal of obsolete Acts, with a view to facilitating the work of a general consolidation. (Stats. 19 & 20 Vict. c. 64; 24 & 25 Vict. c. 101; 26 & 27 Vict. c. 125.)

Statute of Drogheda. [POYNING'S LAW.]

Statute Merchant and **Statute Staple.** These statutes were special forms of bonds or securities for debts, now obsolete. They gave the creditors taking them extraordinary remedies against the body, goods, and lands of the debtor, and were originally permitted only among traders for the benefit of commerce. (Stats. 13 Edw. I.; 27 Edw. III. c. 9; 23 Hen. VIII. c. 6.)

Staurolite (Gr. σταυρός, *a cross*, and λίθος, *stone*). The mineral called *Cross-stone*. [STAUROTIDE.] It is a silicate of alumina with about one-third of the alumina replaced by peroxide of iron, and forms small rhombic prisms (the acute edges of which are frequently replaced), often intersecting and crossing each other at right angles. The most characteristic specimens are from Andreasberg in the Harz, and St. Gotthard in Switzerland; but it is also found in Cornwall and Devon; in Aberdeenshire; and in Wicklow.

Staurolite generally occurs embedded in mica-slate, talc-slate, and clay-slate; sometimes in gneiss.

Staurotide (Gr. σταυρός). A name given by Haüy, and other mineralogists, to the prismatic Garnet, or *Grenatite*. [STAUROLITE.] It occurs in embedded crystals in primary rocks, and is distinguished from Garnet by its crystalline form and infusibility.

Stavesacre. The *Delphinium Staphisagria*. The seeds of this plant are emetic and purgative, owing to the presence of *Delphinia*, a very acrid bitter principle, which, in the dose of a few grains, excites a sense of heat and tingling in various parts of the body. The disease in which it has been chiefly successful is neuralgia, in which it has been applied externally. Stavesacre seeds in the form of ointment or acetous infusion have been used to destroy pediculi.

Stay. A strong rope from the masthead, leading forward and downwards to prevent the spar from falling aft. It takes the name of the mast, as the fore-stay, main-topmast stay, &c. *To stay* means to tack. To be *in stays* is to be in the act of tacking. To *miss stays* signifies to fail in attempting to tack.

Stealer. In Shipbuilding, a short length of plank worked in among the other strakes to facilitate rounding off in parts of great curvature.

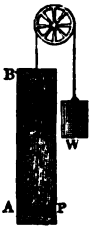
Steam (A.-Sax. stem, Dutch stoom). The elastic fluid into which water is converted by the application of heat.

All liquids whatever, when exposed to a sufficiently high temperature, are converted into vapour. The mechanical properties of vapour are similar to those of gases in general. The property which is most important to be considered, in the case of steam, is the elastic pressure. When a vapour or gas is contained in a close vessel, the inner surface of the vessel will sustain a pressure arising from the *elasticity* of the fluid. This pressure is produced by the mutual repulsion of the particles, which gives them a tendency to fly asunder, and causes the mass of the fluid to exert a force upon the interior surface of any vessel within which it is confined. This pressure is uniformly diffused over every part of the surface of the vessel in which such a fluid is contained; it is to this quality that the mechanical power of steam is due.

To render the chief properties of steam intelligible, it will only be necessary to explain

the phenomena which attend the conversion of water into vapour by the continued application of heat, under the various circumstances of external pressure which present themselves in the processes of nature and art.

Let A B be a tube or cylinder, the magnitude of whose base is a square inch, and let a piston P move steam-tight in it; let it be imagined that under this piston, in the bottom of the cylinder, there is an inch depth of water, which will therefore be in quantity a cubic inch; let the piston be counterbalanced by a weight W acting over a pulley, which shall be sufficient to counterpoise the weight of the piston and its friction in the cylinder; and let the weight W be so arranged that from time to time its amount may be diminished to any required extent. Under the circumstances here supposed, the piston being in contact with the water, and all air being excluded from beneath it, it will be pressed down by the weight of the atmosphere, which we shall assume to be 14¾ lbs. Let it be also supposed that a thermometer is placed in the water under the piston, and that the tube A B is transparent, so that the indications of the thermometer may be observed. The temperature of the water under the piston being reduced to that of melting ice, which is 32° Fahr., let the flame of a lamp be applied under the tube, and let the time of its application be noted. If the thermometer be now observed, it will be seen slowly and gradually to indicate an increasing temperature of the water, the piston maintaining its position in contact with the water unchanged. This augmentation of temperature will continue until the thermometer indicates the temperature of 212°. Let the time be then noted. It will be found that after that epoch, the water will cease to increase in temperature, notwithstanding the continued application of the lamp, the thermometer not rising above 212°. But another effect will begin to be manifested; the piston P will be observed gradually to rise, leaving a space apparently vacant between it and the water. The depth of the water will, however, be at the same time gradually diminished, and the diminution of its depth will be found to bear constantly the same proportion to the ascent of the piston. This proportion will, under the circumstances here supposed, be that of about 1,700 to 1. If the application of the lamp be continued, and the tube have sufficient length, the water will, after the lapse of a certain time, altogether disappear from the bottom of the tube; and when that occurs, the piston will have risen to the height of 1,700 inches, being 1,700 times the original depth of the water.



The tube will now, to all appearance, be empty; but if the apparatus were weighed, it would be found to have the same weight as at the commencement of the experiment. The water, therefore, must still be contained in the tube, though it has assumed an invisible form. To demonstrate its presence, let the lamp be removed; immediately the piston will begin to descend, and the inner surface of the tube will be covered with a dew, which, speedily increasing, will fall to the bottom in drops of water. The piston meanwhile will continue to move downwards, sweeping before it the water from the sides of the tube; and at length will recover its first position, having under it, as at the beginning, a cubic inch of water.

In the above process, the elevation of the piston is produced by the elastic force of the steam into which the water was gradually converted by the lamp. The space between the piston and the water during its ascent, though apparently empty, was filled with steam, which, like air and most other gases, is a colourless and invisible fluid. The proportion of the elevation of the piston to the diminution of the depth of the water being 1,700 to 1, proves that the water in passing into steam increases its volume in that proportion. When the water altogether disappeared, the height of the piston from the bottom of the tube was 1,700 inches; and as the tube under the piston was then filled with the steam into which the water had been converted, it is apparent that the cubic inch of water, in this case, was converted into 1,700 cubic inches of steam.

The pressure of the atmosphere above the piston was, in this instance, overcome by the elastic force of the steam, and the piston, bearing that pressure upon it, was raised to a height of 1,700 inches. In the evaporation, therefore, of this cubic inch of water, a mechanical force has been evolved equivalent to 14¾ lbs. raised to the height of 1,700 inches, or, more exactly, 1,669 inches, according to M. Regnault's determination of the relative volume of steam and water at the atmospheric pressure of 15 lbs. per square inch.

From the moment at which the water began to be converted into steam, the thermometer, having then attained 212°, ceased to rise. Nevertheless, the application of the lamp was continued, and therefore the same quantity of heat per minute was still supplied to the water. Since the water did not increase in temperature, it may be asked what became of this continual supply of heat received from the lamp? It may be said that it was imparted to the steam into which the water was converted; but if the thermometer were raised out of the water, and held in the steam between the water and the piston, it would still indicate the same temperature of 212°. We thus arrive at the fact, that, notwithstanding a large supply of heat imparted to water during its evaporation, heat is sensible neither in the water itself nor in the vapour into which the water is converted.

The quantity of heat which is thus absorbed in converting water into steam is easily determined, the interval of time being noted which elapsed between the first application of the lamp and the moment at which the thermometer ceased to rise. Let us suppose that

interval to be an hour; the interval between the moment when the thermometer ceases to rise and the process of evaporation begins, and the moment at which the last particle of water disappears from the bottom of the tube and the evaporation is completed, will be found to be 5½ hours; and in general, whatever may be the length of time necessary to raise the temperature of the water from 32° to 212°, 5½ times that interval will be necessary for the same source of heat to evaporate the same quantity of water. It follows, therefore, that *to evaporate water under a pressure of* 14¾ *pounds per square inch requires 5½ times as much heat as is necessary and sufficient to raise the same water from* 32° to 212°.

Since the difference between 212° and 32° is 180°, and since 5½ times 180° is 990°, it follows that to convert the water into steam after it has attained the temperature of 212°, as much heat must be supplied to it as would suffice, if it were not evaporated, to raise it 990° higher. The heat thus absorbed in evaporation, and not sensible to the thermometer, is said to be latent in the steam; and the phenomena which have been just described form the foundation of the whole theory of *latent heat*. That this large quantity of heat is actually contained in the steam, though not sensible to the thermometer, admits of easy demonstration, by showing that it may be reproduced by converting the steam into water. If a cubic inch of water, in the form of steam at the temperature of 212°, be introduced into the same vessel with 5½ cubic inches of water at the temperature of 32°, the steam will be immediately converted into water; the temperature of the 5½ inches of ice-cold water will be raised to 212°, and there will be found in the vessel 6½ cubic inches of water at 212°. Thus, while the steam, in reassuming the liquid form, has lost none of its temperature, it has nevertheless given up as much heat as has raised 5½ cubic inches of water from 32° to 212°. It is therefore demonstrated that this quantity of heat was actually in the steam, and that its presence there in the latent state conferred upon the water in the vaporous form the property of elasticity.

We have here supposed that the pressure under which the water in the tube was evaporated was the mean pressure of the atmosphere, or 14¾ lbs. per square inch. Let us now suppose that the piston resting on the water is loaded with a force of 14¾ lbs., besides the pressure of the atmosphere, which may be done by taking 14¾ lbs. from the counterpoise W. If the same process be followed as before, it will now be found that the thermometer will not cease to rise when it has attained 212°; nor will the piston then begin to ascend. The thermometer will, on the other hand, continue to rise until it has attained 250°. It will then, as in the former case, cease to rise; the piston will ascend, and the water will begin to be converted into steam. The proportion, however, between the ascent of the piston and the diminished depth of the water, or, in other words, between the volume of steam produced and the volume of water producing it, instead of being 1,700 to 1, will now be about 900 to 1, being little more than half the former proportion. The force against which the elasticity of the steam, in the present case, acts, is 29½ lbs.; and this force is raised 900 inches by the evaporation of a cubic inch of water. In the former case a force of 14¾ lbs., being half the present force, was raised to 1,700 inches by the evaporation of the same quantity of water, so that in each case the mechanical effect produced is very nearly the same.

If the pressure under which the evaporation is carried on were varied, it would be found that with every increase of pressure the temperature at which the evaporation would commence would be augmented, and that with every diminution of pressure that temperature would be diminished. It would be also found that the volume of steam produced by a cubic inch of water would be less with every increase of pressure under which the evaporation is made; and that the diminution of volume would be nearly, but not in quite so great a proportion, as the increase of pressure. In like manner, if the pressure be diminished, the volume of steam produced by a cubic inch of water will be augmented in nearly, but not quite so great a proportion, as that of the diminution of pressure. From all this, it obviously follows that the mechanical effect evolved by the evaporation of a given volume of water under different pressures is very nearly the same; greater pressures, however, having a slight advantage over lesser ones.

It has been seen that 14¾ lbs. are raised to a height of 1,700 inches by the evaporation of a cubic inch of water under the pressure of 14¾ lbs. per square inch. Now, 1,700 inches are nearly equal to 142 feet; and 14¾ lbs. raised 142 feet is equivalent to 142 times 14¾ lbs. raised one foot, which is equal to very nearly 2,100 lbs. raised one foot. To use round numbers, it may then be stated, that by the evaporation of a cubic inch of water a mechanical force is produced equivalent to a ton weight raised a foot high; and that this force is very nearly the same whatever be the temperature or pressure under which the evaporation takes place.

From what has been above explained, it is apparent that the quantity of sensible heat in steam is augmented with every increase of pressure under which the evaporation is carried on; but if the interval of time be observed which elapses between the first application of the lamp to the ice-cold water in the experiment above described, and the moment at which the last particle of water disappears by evaporation from the bottom of the tube, it will be found that this interval is nearly the same, whatever be the temperature or pressure under which the evaporation takes place. It follows that the actual quantity of heat necessary to convert ice-cold water into steam is nearly the

same, whatever be the pressure of the steam; but as the temperature of steam increases and diminishes as the pressure is increased or diminished, it follows that this given quantity of heat is differently distributed between sensible and latent heat in steam of different pressures. As the pressure is increased the sensible heat is augmented, and the latent heat undergoes a corresponding diminution, and vice versâ. The sum of the sensible and latent heats is, in fact, a constant quantity, or nearly so, the one being always increased at the expense of the other. It has been shown that in converting water at 32° of temperature, and under a pressure of 14¾ lbs. per square inch, into steam, it was necessary first to give it 180° additional sensible heat, and afterwards 990° of latent heat, the total heat imparted to it being 1,170°. The actual temperature to which water would be raised by the heat necessary to evaporate it, if its evaporation could be prevented by confining it in a close vessel, will be found by adding 32° to 1,170°. It may, therefore, be stated that the heat necessary for the evaporation of ice-cold water is as much as would raise it to the temperature of 1,202°, if its evaporation were prevented. If the temperature of red-hot iron be, as is supposed, about 1,200°, and if all bodies become incandescent at the same temperature, it follows that to evaporate water it is necessary to impart to it as much heat as would be sufficient to render it red hot if its evaporation were prevented.

Since water, in passing into steam, undergoes a great enlargement of volume, steam, on the other hand, in being converted into water, undergoes a corresponding diminution of volume. It has been seen that a cubic inch of water, evaporated at the temperature of 212°, swells into 1,700 cubic inches of steam. It follows, therefore, that if a close vessel, containing 1,700 cubic inches of such steam, be exposed to cold sufficient to take from the steam all its latent heat, the steam will be reconverted into water, will shrink into its original dimensions, and will leave the remainder of the vessel a vacuum. This property of steam has supplied the means, in practical mechanics, of obtaining that amount of mechanical power which the properties of the atmosphere confer upon a vacuum. If by any means whatever the space in a cylinder under the piston be rendered a vacuum, the atmospheric pressure will take effect above the piston, and will urge the piston downwards with a force amounting to about 15 lbs. on each square inch on the surface of the piston. To render steam available for this purpose, it is only necessary to inject it into the cylinder until it expels from the cylinder all the atmospheric air or other uncondensable gases which the cylinder contains; and when that is effected, the pure steam which remains in the cylinder being suddenly condensed by the application of cold, leaves the cylinder a vacuum, and gives effect to the atmospheric pressure above the piston, as before explained. This is, in fact, the principle of the atmospheric engine, which is the species of engine which remained in use up to the time of Watt.

In the mechanical operation of steam, which has been already explained, the pressure, density, and temperature of the steam are supposed to remain the same during its action, and the mechanical effect is produced by the continual increase of the quantity of steam produced by evaporation. Thus, the piston in the apparatus represented in the figure is moved upwards, not by any change in the temperature, density, or pressure, but by the increased volume acquired by the continual production of steam. It has been proved that by this process alone the evaporation of a cubic inch of water, whatever be the pressure under which it takes place, evolves a mechanical force equivalent to a ton weight raised a foot high. But if, after this evaporation has been completed, the steam be separated from the water which produced it, and the load on the piston be gradually diminished, the steam will expand by moving the piston upwards in virtue of its excess of pressure, and this expansion will continue until the pressure of the steam shall be reduced to equality with the load on the piston. All mechanical effect developed in this process is due to the steam itself, independently of any further evaporation.

To make this important quality of the expansive action of steam understood, let us suppose the piston loaded with a pressure amounting to four times that of the atmosphere, including that of the atmosphere itself. If the water under the piston be evaporated under this pressure, it will have a temperature of about 292°, and by its evaporation the piston will be raised 40 feet. This will, therefore, be the whole mechanical effect arising from the immediate evaporation of the water. But when the evaporation has been completed, and the piston, with its load of four atmospheres, stands suspended at 40 feet above the bottom of the tube, let a pressure equal to that of one atmosphere be removed from the piston. The remaining pressure of three atmospheres being less than that of the steam below the piston, the piston will be raised, and will continue to rise until it has attained a height of about 50 feet, and the temperature of the steam thus expanded will fall to about 275°; and its pressure being reduced to that of three atmospheres, it will cease to rise. By this process, therefore, a mechanical force has been obtained from the steam equal to the weight of three atmospheres raised 10 feet in addition to the effect obtained by immediate evaporation; but the expansive action does not stop here. Let it be supposed that the piston is again relieved from the pressure of another atmosphere, the superior pressure of three atmospheres below will cause it to rise, and it will ascend to the height of about 75 feet, the temperature of the steam falling to about 250°, and its pressure being reduced to two atmospheres. A further mechanical effect equivalent to the weight of two atmospheres raised to about 25 feet has

thus been obtained; and it is evident that by constantly and gradually diminishing the load on the piston, an additional effect may be always obtained from a given amount of evaporation, to an extent which is only limited by practical circumstances which restrain the application of this expansive principle. Since the cost of producing steam as a mechanical agent depends chiefly on the quantity of fuel necessary to effect the evaporation of a given volume of water, it follows that all the mechanical effect obtained by this principle of expansion is so much power added to the steam without further expense. Its importance, therefore, will be obvious in the economy of steam power. For the manner of rendering it available in steam machinery, see STEAM ENGINE.

The temperature and pressure of steam produced by immediate evaporation, when it has received no heat, save that which it takes from the water, have a fixed relation one to the other. If this relation were known, and expressed by a mathematical formula, the temperature might always be inferred from the pressure, or vice versâ. But physical science has not yet supplied principles by which such a formula can be deduced from any known properties of liquids. In the absence, therefore, of any general relation established by direct reasoning, empirical formulæ have been proposed, which express, with more or less precision, this relation in different parts of the thermometric scale. These formulæ have been so constructed as to give results which nearly agree with the results obtained by experiment. One set of experiments to ascertain the relative bulks of steam and water was made by Watt at an early period of his career, and these experiments were subsequently repeated by his assistant Southern, with great care and skill. Southern's formula for determining the pressure of steam of any given temperature is probably more widely identified than any other with engineering practice, and it gives results sufficiently accurate for engineering purposes. This formula is as follows: If F represent the elastic force of the steam in inches of mercury, and t its corresponding temperature in degrees of Fahrenheit's thermometer,

$$\text{then} \qquad F = \left\{\frac{t + 51{\cdot}3}{135{\cdot}767}\right\}^{5{\cdot}13} + 0{\cdot}1.$$

The numerical process indicated by this formula being somewhat complicated, it may for greater convenience be performed by logarithms, as follows:—

To find the elastic force of steam in inches of mercury by Southern's formula.

Rule.—*To the given temperature in degrees of Fahrenheit's thermometer add* 51·3 *degrees: then from the logarithm of the sum subtract* 2·1327940, *the logarithm of* 135·767. *Multiply the remainder by the index* 5·13, *and to the natural number answering to the sum add the constant fraction* 1-10*th*. *The result will be the elastic force of the steam in inches of mercury.*

One of the most important courses of experiments which have been made upon this subject is that undertaken by a committee of the French Institute, consisting of MM. Prony, Arago, Gerard, and Dulong, in consequence of an application from the French government to the Academy to point out the best means of preventing accidents from the bursting of the boilers of steam engines. The experiments were conducted chiefly by Arago and Dulong, and were certainly not only extremely delicate as to their management, but the most hazardous which science and art owe to the courage and zeal of philosophers. Steam was produced of a sufficient pressure to force a column of mercury up a glass tube to the height of nearly 43 feet; an atmosphere being measured by a column of mercury measuring 29·922 inches. The following table exhibits the temperatures and corresponding pressures of steam, as determined by these experiments, up to fifty atmospheres.

Pressure in Atmospheres	Temperature	Pressure in Atmospheres	Temperature
1	212°	13	380·66°
1½	234	14	386·94
2	250·5	15	392·86
2½	263·8	16	398·48
3	275·2	17	403·83
3½	285	18	408·92
4	293·7	19	413·78
4½	300·3	20	418·46
5	307·5	21	422·96
5½	314·24	22	427·28
6	320·36	23	431·42
6½	326·26	24	435·56
7	331·7	25	439·34
7½	336·86	30	457·16
8	341·78	35	472·73
9	350·78	40	486·59
10	358·88	45	499·14
11	366·85	50	510·6
12	374		

The last six temperatures in the above table are deduced by calculation from the formula

$$e = (1 + 0{\cdot}7153t)^5,$$

in which e expresses the elasticity in atmospheres, and t the temperature in centième degrees, beginning from 100°, and proceeding upwards. The methods employed in this magnificent course of experiments will be found detailed in the *Annales de Chimie et de Physique*, tome xliii. p. 74.

The most recent and trustworthy experiments upon the heat and pressure of steam have been made by M. Regnault in France.

M. Regnault has shown that the total amount of heat existing in a given weight of steam increases with the pressure. Thus, in steam with a pressure of 14·7 lbs. upon the square inch, the sensible heat of the steam is 212°, the latent heat 966·6°, and the sum of the latent and sensible heats 1,178·6°; whereas, in steam of 90 lbs. upon the square inch the sensible heat is 320·2°, the latent heat 891·4°, and the sum of the latent and sensible heats 1,211·6°. There is, therefore, a difference of 33° in the total heat of a pound of water

raised into steam of 14·7 lbs. pressure and that of a pound of water raised into steam of 90 lbs. pressure; so that the high steam if expanded into low will have an excess of temperature beyond that necessary for the maintenance of the vaporous form, or, in other words, will be in the state of surcharged steam. Surcharged steam, or steam to which more heat is imparted than is necessary for the maintenance of the vaporous form, comes under the same physical laws as air and other permanent gases. And with all gases, when the temperature is constant, the pressure varies simply as the density, or inversely as the volume. When the pressure is constant, the dilatation is uniform with uniform additions of heat, and is at the rate of $\frac{1}{490}$ of the volume at 32° for every additional degree of temperature. When the volume is constant, the increase of pressure is $\frac{1}{490}$ of the pressure, at 32° for each additional degree of temperature. In the *Edinburgh New Philosophical Journal* for July 1849, a formula is given by Mr. Rankine, which educes results very nearly corresponding with those which M. Regnault obtained by experiment; and from this formula, therefore, the most material of M. Regnault's results may be obtained. Mr. Rankine assumes a point of temperature t, which is 462·28° of Fahrenheit's scale below the ordinary zero of that scale, as a new *absolute zero*, and he supposes the boiling point of the water to have been adjusted under a pressure of 29·922 inches of mercury; so that 180° of Fahrenheit may be exactly equal to 100° of the centigrade thermometer. The formula is applicable for finding the elasticity of other vapours besides that of water; but three constants, α, β, γ, have to be determined for each fluid by experiment. If P be the pressure of the steam and t the point of absolute zero, as explained above, then the formula for calculating the pressure from the temperature is—

$$\log P = \alpha - \frac{\beta}{t} - \frac{\gamma}{t^2},$$

and the inverse formula for calculating the temperature from the pressure is—

$$\frac{1}{t} = \sqrt{\frac{\alpha - \log P}{\gamma} + \frac{\beta^2}{4\gamma^2}} - \frac{\beta}{2\gamma}.$$

The values of the constants have been derived from M. Regnault's experiments, and they are as follow:—

$$\log \beta = 3{\cdot}4403816\,;\ \log \gamma = 5{\cdot}5926244\,;$$

$$\frac{\beta}{2\gamma} = 0{\cdot}0035189\,;\ \frac{\beta^2}{4\gamma^2} = 0{\cdot}000012364.$$

The value of α, other things being the same, depends upon the measure of elasticity adopted. If it be inches of mercury, the value of α will be 6·426421; if it be pounds avoirdupois on the square inch, the value of α will be 6·117817.

The following table is derived from M. Regnault's experiments, with the addition of a column showing the volume of the steam relatively with the volume of the water from which it is generated, computed by Mr. D. K. Clark, and given in his work on Railway Machinery. In this table we have the total pressure of the steam in lbs. per square inch, its relative volume as compared with that of the water from which it is produced, its temperature, its total heat, or, in other words, the sum of its latent and sensible heats, and finally the weight of a cubic foot of the steam at the several pressures or densities enumerated. The steam is supposed in every case to be saturated with water.

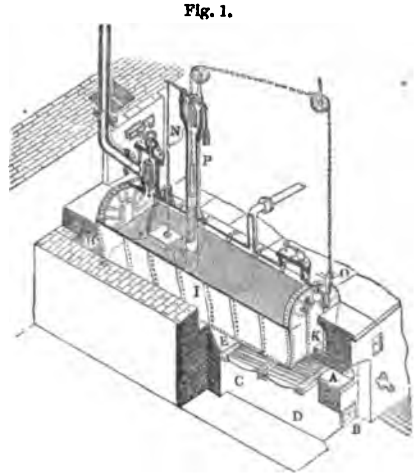
Steam Boiler. A vessel in which water is converted into steam for the purpose of supplying steam engines, or for any other purposes for which steam is used in the arts, or in domestic economy.

Waggon Boiler.—One of the oldest forms of boiler used for land engines, is that called the *waggon boiler*, an isometric view of which is given in fig. 1; but this boiler has now almost entirely disappeared, owing to its small evaporative power compared with the consumption of fuel, and to its incapacity to resist the pressure of steam which recent discoveries have shown to be necessary for the economical working of the steam engine.

Fig. 1.



The proper level of the water within this boiler is maintained by means of a balanced buoy or float communicating with the rod N, which is attached to a lever set on the top of the stand-pipe P. The top part of this pipe is widened out so as to form a small cistern into which the water for replenishing the boiler is pumped by the engine; and a valve in the bottom of the cistern, when opened by the lever communicating with the rod N as the float subsides from the falling of the water-level, admits a sufficiency of feed water to replace the water removed by evaporation. When there is already a sufficiency of water in the boiler the valve in the feeding cistern remains closed, and the excess of water in such a case runs to waste through an overflow pipe provided for that purpose.

In marine and locomotive boilers the use of a float for regulating the admission of the feed water is inapplicable, and there the attendant has from time to time to adjust a cock in the feed-pipe, so as to admit the proper quantity of water. To enable him to know at what level the water stands within the boiler a succession of cocks, called *gauge-cocks*, is attached to the boiler, rising one above the other; and the highest of these cocks when turned should always let out steam, and the lowest water. A glass tube is also affixed perpendicularly to the outside of the boiler in such a manner, that its upper extremity communicates with the steam within the boiler, and its lower extremity with the water. The water consequently stands in the tube at the same level as in the boiler, and the height of the water in the boiler is thus rendered visible. Cocks are provided at the top and bottom of the tube, so that if the tube happens to be

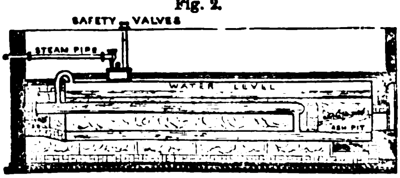
broken, the issue of the steam or water may be prevented.

The draught through the furnace of land boilers is regulated by a plate of metal or *damper*, as it is called, which closes, to a greater or less extent, the opening of the flue, in the manner of a sluice. A damper of this kind is seen at O, and it is counterpoised by a weight in the stand-pipe P, by means of a chain passing over pulleys. When the pressure of the steam in the boiler rises beyond the desired point, the water is forced up by it into the pipe P to a more than usual height. The weight in P being thus floated up, the damper at O preponderates, and partly closes the flue, whereby the intensity of the draught through the furnace is diminished, and less steam is raised. To provide an escape for the superfluous steam, which if suffered to accumulate would burst the boiler, one or more valves, opening upwards and loaded by a weight or spring to a sufficient degree to balance the pressure of the steam, must be applied. This species of valve is called the *safety-valve*, and a valve of this kind is seen in the figure affixed to the top of the boiler near N: a pipe proceeds from the safety-valve, which conducts the waste steam into the atmosphere.

Cylindrical Boilers.—The usual pressure of steam employed in waggon boilers is from 3 to 5 lbs. per square inch. In many engines, however, and especially in those which work expansively, it is found expedient to use steam of a higher pressure. To sustain this pressure waggon boilers are not well adapted, and hence a new class of boilers has been introduced of a cylindrical form, and which are therefore termed *cylindrical boilers*. These boilers can withstand a considerable pressure without danger. Their construction in the subordinate features is very various, but a form much approved is that known as the *Cornish boiler*.

Cornish Boiler.—The boilers used at the mines in Cornwall, have long been celebrated for great economy of fuel and other distinguishing circumstances.

Fig. 2.



A very good example of a Cornish boiler is

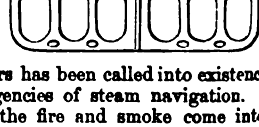
Fig. 3.

represented in figs. 2 and 3; fig. 2 being a longitudinal section of a Cornish boiler, and fig. 3 a transverse section. The furnace is placed, not beneath the boiler, but within it, and the flame and hot air pass through a central flue to the end of the boiler. They next pass along the boiler sides, and finally beneath the boiler bottom, before they escape to the chimney. A brick wall is built at the back end of the fire bars, to form the termination of the furnace. This wall is called the *furnace bridge*. Behind the bridge in some Cornish boilers a pipe containing water extends horizontally within the flue, communicating at the one end with the bottom part of the boiler, and at the other end with the top part of the boiler. The hot air impinging upon this pipe causes the water within it to boil, and a constant circulation of the water is maintained within it. In modern boilers, however, this pipe is omitted. This boiler, like the waggon boiler, is set in brickwork, and it is also covered over with a brick arch, for the purpose of retaining the heat. But a vacant space is left between this brick arch and the top of the boiler for the purpose of enabling the boiler to expand without disturbing the brickwork.

One of the most remarkable peculiarities of the Cornish boilers is the slowness of the combustion in the furnaces, and the large amount of heating surface allowed for the evaporation of the water. Thus, in certain experiments upon Cornish, waggon, and locomotive boilers, recorded in Mr. Bourne's work upon the steam engine, it was found that the number of pounds of fuel burned upon each square foot of fire-grate in the hour was, in the Cornish boiler, 3·46 lbs.; in the waggon boiler, 10·75 lbs.; and in the locomotive boiler, 79·33 lbs. The number of square feet of heating surface of the boiler employed to evaporate a cubic foot of water in the hour was, in the Cornish boiler, 69·58 square feet; in the waggon boiler, 9·96 square feet; and in the locomotive boiler, 6·06 square feet. The number of cubic feet of water evaporated by 112 lbs. of fuel was, in the Cornish boiler, 18·87 lbs.; in the waggon boiler, 13·91 lbs.; and in the locomotive boiler, 11·14 lbs.

Marine Boilers.—Boilers set in brickwork being ineligible in steam vessels, a distinct class

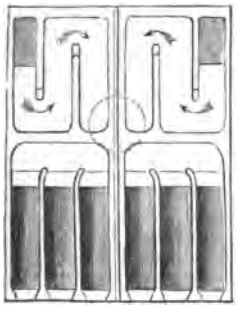
Fig. 4.



of boilers has been called into existence to meet the exigencies of steam navigation. In these boilers the fire and smoke come into contact only with metallic surfaces surrounded by water. Marine boilers consist of a series of large iron vessels, in which are set a number of metallic furnace chambers, connected with metallic flues winding within the boiler, or with a number of short metallic tubes of small diameter which deliver into the chimney.

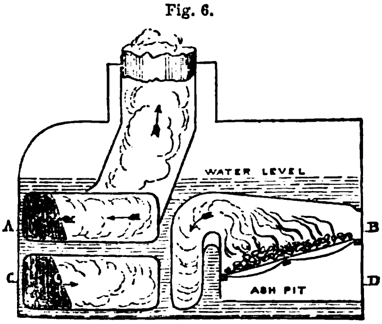
Boilers with large flues winding within them are termed *flue boilers*, and boilers in which the heat is communicated by means of a faggot of small tubular flues passing through the water are called *tubular boilers*. In figs. 4, 5,

Fig. 5.



6, 7, and 8, representations are given of a flue boiler. Fig. 4 is a front elevation of this boiler; fig. 5 a horizontal section through the line A B, seen in fig. 6, and fig. 7 a horizontal section through the line C D, seen in fig. 6. Fig. 6 is a perpendicular section through the line G H, seen in fig. 7. It will be obvious from these figures, that the boiler consists of two portions

Fig. 6.



placed side by side, and each containing three furnaces. The smoke from each group of three furnaces passes into one flue, which winds until it reaches the corner of the boiler, as shown in

Fig. 7.

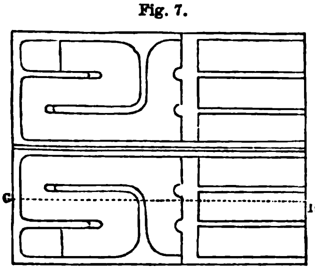


fig. 7. The flue then ascends perpendicularly upwards, and winds in a similar manner through an upper tier of flues until it finally reaches the chimney in the centre of the boiler, represented by the dotted circle in fig. 5.

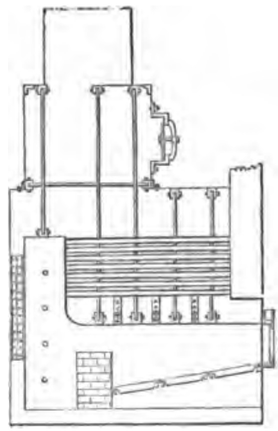
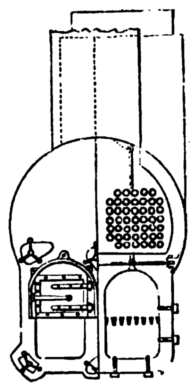
Fig. 8.



Figs. 8 and 9 are representations of a tubular boiler; fig. 8 being a longitudinal section made perpendicularly through the boiler, and fig. 9 an end view, with one half cut transversely through the furnace and boiler. There are two furnaces in the boiler, and the smoke and flame, after passing over the furnace bridge, ascend into a bundle of small brass tubes, and pass through them on their way to the chimney. Upon the top of the boiler a chest is placed to serve as a receptacle for the steam, which there deposits any particles of water that may happen to be mixed with it. Iron rods pass perpendicularly and horizontally within the boiler to strengthen it, and to enable it to withstand a considerable pressure.

Fig 9.



Nearly all marine tubular boilers are formed on this general type. Sometimes the boiler shell is square instead of waggon-formed, and has more furnaces set within it; but these differences are not very material. Tubular boilers are now very largely employed in steam vessels. They were patented by Mr. Bourne in 1838, but first came into general use about 1844. They are lighter than flue boilers, and occupy less space; and if they are properly constructed they are not difficult to keep in repair.

The consumption of fuel per horse-power in marine boilers is very extravagant, and attempts have recently been made to economise

it by the construction of tubular boilers, in which the water and steam occupy the interior of the tubes, whilst the fire and heated products of combustion are applied to the exterior. By this construction, together with superheating and expansion, the hourly consumption of fuel per actual horse-power has been reduced from 6 lbs. or 7 lbs. to 2 lbs.; but practical difficulties arise in the use of these boilers which have not hitherto been entirely overcome.

Proportions of Marine Boilers.—Marine boilers are commonly proportioned according to the nominal power of the engines which they are employed to drive. But this is not a proper practice. Their dimensions should be determined by the number of cubic feet of water which they are required to evaporate in the hour, and not by the nominal power. To evaporate a cubic foot of water per hour in *flue boilers*, the following are the proper proportions: heating surface, 8 square feet; fire grate, 70 square inches; sectional area of flue, 13 square inches; sectional area of chimney, 6 square inches; area over furnace bridges, 14 square inches; area of flue to area of fire grate, as 1 to 5·4; total heating-surface in feet, divided by the area of flue in feet, $\frac{1}{88}$. To evaporate a cubic foot of water per hour in *tubular boilers*, the following are the proper proportions: heating surface, 9 square feet; fire grate, 70 square inches; sectional area of tubes, 10 square inches; sectional area of back uptake, 12 square inches; sectional area of front uptake, 10 square inches; sectional area of chimney, 7 square inches; ratio of length of tube to diameter, $\frac{1}{28}$ to $\frac{1}{30}$; ratio of length of tube to area of tube, $\frac{1}{13}$ to $\frac{1}{15}$; cubical content of boiler, exclusive of steam chest, 6·5 cubic feet; cubical content of steam chest, 1·5 cubic foot.

The amount of mechanical power producible by a cubic foot of water evaporated per hour by the boiler, depends very much upon the manner in which the steam is used in the engine. In the original engines of Watt, a cubic foot of water evaporated in the hour produced only steam sufficient for one horse-power; but in modern marine engines, which work to some extent on the expansive principle, from $1\frac{1}{4}$ to 2 horse-power are produced by the evaporation of a cubic foot of water per hour—a horse-power being reckoned as equivalent to 33,000 lbs. raised one foot high in the minute.

Incrustation of Marine Boilers.—One of the greatest inconveniences attending the original application of the steam engine to the navigation of the ocean, arose from the gradual accumulation of salt within the boiler in consequence of the necessity of feeding the boiler with salt water from the sea. Sea-water contains about $\frac{1}{33}$ of its weight of saline ingredients; and it is found that when the density of water is increased by evaporation until it contains $\frac{4}{33}$ of its weight of saline ingredients, some of those ingredients begin to be deposited upon the flues, forming upon them a stony crust which retards the transmission of the heat. It is hence very important that the water in marine boilers should never contain more than $\frac{2}{33}$ of salt, and it is easy to keep the water below this point of concentration by blowing out a sufficiency of the over-salted water, and filling up the boiler with the fresher water of the hot well or the sea. Hydrometers are now very generally provided in steam vessels, to enable the engineer to determine the density of the water; and in every case it is right to practise blowing out to such an extent as will prevent the formation of saline or stony incrustations upon the flues. In the case of pressures above 40 lbs., however, sulphate of lime is precipitated from sea water, without any concentration at all, by the mere effect of the high temperature; and surface condensers, which supply fresh water for feeding the boiler, are now very generally employed.

Boiler Explosions.—The explosion of a boiler generally arises from one of two causes: either from the strength of the boiler being inadequate to bear the pressure accidentally or perhaps habitually put upon it, so that it at last gives way; or from the flues having been suffered by an improper subsidence of the water to become red hot, when they cease to be able to sustain the pressure to which they are exposed. A marine boiler may also burst if the water within it be suffered to attain such a point of saturation that salt is deposited to a great thickness upon the flues; for the metal composing the flues, being in such a case unable to transmit the heat to the water with sufficient rapidity, may become red hot, and may thereby lose the strength necessary to withstand the pressure of the steam. Nearly all explosions, however, are traceable either to an undue pressure in the boiler or to a deficiency of water. Sometimes the safety valve becomes deranged when the steam is unable to escape from the boiler. This occurrence will always become discoverable by a reference to the steam gauge, which shows by the position of the mercury the pressure of the steam. And all the gauge cocks should then be opened, and the blow-through valve of the engine should also be opened, so as to let the steam escape in that direction. If the flues have become red hot from a deficiency of water, on no account must more water be added; but the pressure of the steam must be *gradually* reduced, and the fires should be immediately raked out. To reduce the pressure of the steam suddenly, would cause a sudden ebullition, which might carry the water over the red-hot flues, and perhaps cause the boiler to explode.

Proper Method of Feeding Furnaces.—The coals should be broken up into small pieces, and sprinkled thinly and evenly over the fire, a little at a time. The fire should be without any holes or uncovered places in it, as the efficacy of the fuel would be greatly diminished

by the cooling effect of the cold air which would thus enter. The absolute thickness of the stratum of incandescent fuel should be regulated to a considerable extent by the quality of the draught through the furnace. If the stratum of coal be thick while the draught is sluggish, the carbonic acid resulting from combustion combines with an additional atom of carbon in passing through the fire, and is converted into carbonic oxide, which carries off a portion of the fuel to waste; whereas if the stratum of coal is thin, while the draught is very rapid, an injurious refrigeration is occasioned by the large excess of air, beyond that necessary for combustion, which passes through the fire. For further information about steam boilers, see *A Treatise on the Steam Engine*, by the Artizan Club; *A Treatise on Steam Boilers*, by R. Armstrong, C.E.; *A Catechism of the Steam Engine*, by J. Bourne, C.E.; and *A Handbook of the Steam Engine*, by J. Bourne, C.E.

Steam Carriage. A carriage, propelled by steam, intended to run on common roads at a considerable rate of speed. Before the great expansion of the railway system had taken place in the ten years succeeding the opening of the Liverpool and Manchester Railway in 1830, many projects were propounded for running steam carriages on common roads, to supersede coaches drawn by horses; and various steam coaches having this object in view were constructed by different persons, of which the coaches of Gurney, Hancock, Ogle and Summers, and Scott Russell, obtained the greatest notoriety. But as it could not be hoped that a steam coach on a common road could run as fast, or draw such heavy loads, as a locomotive on a railway, and as railways were now extending throughout the country, the inducement for the adoption of steam coaches was taken away, and they were consequently abandoned. This result, however, is merely accidental to the simultaneous extension of the railway system, and constitutes no reason why steam coaches on the common road should not be adopted in countries where railways do not exist, or have received but little developement. The mechanical features of the steam carriages of different constructors were very different, especially in the construction of the boiler. Gurney's boiler was composed of circuits of tubes, placed side by side and filled with water, and the tubes opened into a vessel called the *separator*, where the steam was disengaged from the water. This boiler was very bad. Hancock's boiler consisted of an arrangement of narrow vertical water spaces, alternated by narrow vertical flues through which the heat ascended; and Ogle and Summers' boilers consisted of a number of vertical tubes, which were heated by the fire, and within each of which there was an internal tube to permit the water to descend while the water and steam ascended through the intervening annulus, as in the boiler known as Field's boiler. [STEAM FIRE ENGINE.] In most cases, the cylinders of the steam carriages were horizontal, and the connecting rod turned round the wheel as in locomotives. The only species of steam vehicle now used on common roads, is a kind of steam waggon called a TRACTION ENGINE.

Steam Chest. A chest or box placed on the top of marine boilers to serve as a receptacle or reservoir for the steam.

Steam Coal. A variety of coal intermediate between bituminous coal and anthracite, burning with a good flame and lasting for a long time without being consumed. Excellent steam coals are obtained both from the Newcastle coal field, chiefly the northern beds, and from South Wales, and enormous quantities are consumed and exported from both localities. It is essential for ocean-bound steamers that they should have a coal of this kind which is free from pyrites. Such coals are found generally in certain parts of a coal-field, and are not characteristic of an entire district. The powder and dust of some kinds of coal are capable of being worked up into an admirable artificial fuel of this kind, which possesses the advantage of packing more closely. Hitherto, however, it has not been found possible to make a good artificial fuel that shall stand exposure to the tropics without risk of spontaneous combustion. [COAL.]

Average Value of Coals for the Generation of Steam.—The following table, taken from *Reports on Coals suited to the Steam Navy*, by Sir H. de la Bèche and Dr. Lyon Playfair, shows the average value of coals from different localities:—

Locality	Evaporating Power, or Number of Lbs. of Water evaporated from 212° by 1 Lb. of Coal	Rate of Evaporation, or Number of Lbs. evaporated per Hour	Weight in Lbs. of one Cubic Foot of Coal as used for Fuel	Space occupied by one Ton in Cubic Feet	Cohesive Power of Coals, or Per-centage of large Coals after loading and unloading	Per-centage Amount of Sulphur in Coals
Wales	9·05	448·2	53·1	42·71	60·9	1·42
Newcastle . . .	8·37	411·1	49·8	45·3	67·5	0·94
Lancashire . . .	7·94	447·6	49·7	45·15	73·5	1·42
Scotland . . .	7·70	431·4	50·0	49·99	73·4	1·45
Derbyshire . .	7·58	432·7	47·2	47·45	80·9	1·01

Steam Cultivation. After years of expensive labour and experiment, steam power has been successfully applied to the cultivation of land. The two principal methods in vogue are those of William Smith of Woolstone, Buckinghamshire, who has for many years cultivated his own farm by steam power, and the late John Fowler of Leeds, whose untimely death occurred just as he had perfected his machinery and seen it in successful operation all over the country. Mr. Smith's plan, which has been adopted by Messrs. Howard of Bedford, and several other manufacturers of agricultural machinery, requires the use of one of the ordinary locomotive agricultural steam engines. This is planted in a corner of the field to be cultivated, and there works a double windlass, off one cylinder of which a wire rope is delivered while its farther end is being coiled upon the other. This rope is taken round the field guided by *snatch-block* pulleys at the angles, and lies along the furrow in which the cultivating tool, placed as it were a link in it, is working. The tool, whether a grubber or a plough, is thus drawn to and fro across the field from one side of it to the other, and the pulleys anchored at each end of the furrow are shifted backwards step by step as the work proceeds. As the tool gets over the untilled land lying between it and the engine, the shortening rope is coiled upon the windlass, only so much being at any time let out and used as is required.

The cost of labour is rather greater on this plan than on the other; two men being constantly required at the ends of the working furrow in shifting the anchored pulley blocks around which the rope works. In Mr. Fowler's plan, these men are not needed. The engine travels along the headland, and a self-travelling anchor works along the other headland, while the wire rope employed to draw the tool to and fro between them works around the large horizontal pulleys carried by each. The tool is either a framework of ploughs turning three or four furrow slices together, or a large cultivator, and instead of turning at the land's end as Smith's cultivator needs to do, a double tool is balanced over a pair of wheels, and the two ends come into operation alternately. Messrs. Howard employ both ploughs and cultivators, in which a similar result is obtained in a somewhat different manner. Fowler's method is modified in some cases by the employment of double engines, one at each end of the furrow along which the tool is drawn; and a single rope being wound up alternately on the windlasses beneath these engines draws the plough or cultivator to and fro as each engine in its turn is set agoing.

The advantage of steam cultivation over that by horses lies mainly in the avoidance of that trampling by draught animals which to a great extent destroys the tillage. A cultivator is drawn to and fro on large wheels, and the tilth effected by it is obtained with hardly any drawback. There is, further, the power of accomplishing large quantities of work while the soil is in the fittest condition. In ordinary horse-power cultivation of clay lands, expensive teams have to be kept throughout the year for the sake of their services during the two or three months when alone clay land is in the right state for cultivation. On such land, therefore, a steam engine, which is inexpensive except when actually at work, is on every ground preferable to horse-power for the accomplishment of all tillage operations.

Steam Engine. A machine in which the mechanical power developed in the evaporation of water is rendered available as a moving power. Steam engines vary much in magnitude, form, and proportions, as well as in the details of the machinery by which the power of the steam is adapted as a prime mover. The forms of steam engine, and the mode of its application to transport by land and water, have been consigned to separate articles. [LOCOMOTIVE ENGINE; RAILROADS; STEAM NAVIGATION; TRACTION ENGINE.]

History of the Steam Engine.—Various attempts at the mechanical application of steam on a small scale were made at very early periods in the history of mechanical science. Hero of Alexandria has left a description of a small machine, in which a motion of continued rotation was imparted to an axis by the reaction of steam issuing from lateral orifices in arms placed at right angles to the revolving axis. The date of this invention is about a century before the birth of Christ. Branca, an Italian engineer, about the beginning of the seventeenth century, proposed to give motion to a wheel by a blast of steam blown tangentially against it; and about the same period, De Caus, a French engineer, described a machine by which a column of water might be raised by the pressure of steam confined in a vessel above the water to be elevated. But in the descriptions developements which these projectors have left, there is nothing to demonstrate that they were acquainted with those physical properties of elasticity and condensation [STEAM] on which all the power of steam, as a mechanical agent, depends. In the middle of the seventeenth century, or somewhat later, the celebrated marquis of Worcester published, in his work called *A Century of Inventions*, a description of a steam engine to be worked by steam of high pressure, which, though not minute and explicit in its details, is still such as it is difficult to conceive being written by anyone unacquainted with the elastic force of steam. Towards the close of that century, Papin, a French engineer who was professor of mathematics at Marbourg, directed his attention to the properties of steam, and conceived the idea of obtaining a moving power by introducing a piston into a cylinder and producing a vacuum under it by the gradual condensation of steam by cold. But the steam was also to be generated in the cylinder by the application of a fire; and it was not to be condensed by the application of cold substances to the cylinder, but was to cool gradually of

its own accord. The details of the project were altogether so imperfect as to render it useless in practice. There is no evidence of Papin having carried his idea even so far as the construction of a model until after machines worked by steam had been constructed elsewhere, and he then relinquished his own project in favour of that of Savery.

The first actual working steam engine of which there is any detailed account was constructed by Thomas Savery, an Englishman, to whom a patent was granted for it in the year 1698. Savery reproduced the method of forming a vacuum by the condensation of steam, apparently without being aware of the paper written by Papin. He combined this with the elastic pressure of steam as proposed by Lord Worcester, and constructed an engine, which, for a time, was used to a considerable extent for raising water. Savery's steam engine consisted of a strong copper vessel formed in the shape of an egg, having a tube or pipe at the bottom, which descended to the place from which the water was to be drawn, and another at the top which ascended to the place to which it was to be elevated, and which descended within the oval vessel nearly to the bottom. This oval vessel was filled with steam supplied from a boiler, by which the atmospheric air by which it was previously filled was first blown out of it. When the atmospheric air was thus expelled, and nothing but pure steam was left in the vessel, the communication with the boiler was cut off, and cold water was poured on the external surface of the vessel. The steam within it was thus condensed and a vacuum produced, and the water was drawn up from below in the usual way by suction. The oval steam vessel was thus filled with water; a cock at the top of the lower pipe was then closed, and steam was introduced from the boiler into the oval vessel above the surface of the water. This steam, being of high pressure, forced the water up the ascending tube, from the top of which it was discharged; and the oval vessel being thus again filled with steam, the vacuum was again produced by condensation, and the same process was repeated. By using two oval steam vessels which would act alternately, one drawing water from below, while the other was forcing it upwards, an uninterrupted discharge of water was produced.

Owing to the danger of explosion, from the high pressure of the steam which was used, and from the enormous waste of heat by unnecessary condensation, these engines soon fell into disuse, and an engine was introduced consisting of a cylinder and piston—the piston being connected to one of the ends of a great beam, hung like the beam of a pair of scales, while to the other end of the beam the pump rods of the mine were attached. The cylinder was close at the bottom and open at the top, and when the steam from the boiler was introduced beneath the piston, the pump rods, being heavier than the piston, preponderated, and the piston ascended to the top of the cylinder. The ingress of steam from the boiler was then stopped, and the steam within the cylinder being gradually condensed, the piston descended and made a stroke. This machine was invented by Newcomen, a blacksmith, and Cawley, a glazier, at Dartmouth, in Devonshire. In the first engine constructed by them, the condensation was effected by the affusion of cold water upon the external surface of the cylinder, which was introduced into a hollow casing by which it was surrounded. The discovery of condensation by jet within the cylinder, one of the most important steps in the improvement of the steam engine, was accidental. It happened that a small hole occurred in the bottom of the cylinder of an engine, by which the water let in to cool its external surface oozed in, forming a little jet. The effect was a much more rapid and perfect condensation than ever was or could be effected by external cold. Thenceforward, the method of condensation by jet was adopted, and has ever since been used.

In the early atmospheric engines, the cocks by which the steam was admitted and condensed, and by which the injected water and condensed steam were drawn off, were worked by hand; and as the labour was light and monotonous, and required no skill, boys were employed for the purpose, called *cock boys.* It happened that a cock boy, named Potter, having an itch for play, and endowed with more ingenuity than industry, imagined that by tying strings to the cocks, and connecting them with the working beam above the cylinder, regulating the action by carrying them under or over certain pipes, he could make the beam, as it ascended and descended, open and close the cocks more regularly and effectually than he found himself able to do. This he accordingly accomplished, and was habitually absent from the engine-house, enjoying himself with his playfellows, when his employers were giving him credit for extraordinary industry and regularity in the discharge of his duties. The engine, in fact, by this expedient, nearly tripled its work. Thus, by the ingenuity of a child, the steam engine was first endowed with those qualities of an automaton which have ever since rendered it an object of admiration and interest. The engine, thus endowed with new powers, was subsequently greatly improved in its details by Beighton and by Smeaton. As thus improved, it held its place as the great instrument for the drainage of mines until the epoch which was rendered memorable by the inventions and discoveries of Watt; and it may even still be seen in use at coal mines, and in other situations where coal is cheap. In these early engines the cylinder was open at the top, and the piston was pressed down by the weight of the atmosphere. They were therefore called *atmospheric engines.*

Watt was a mathematical instrument maker in Glasgow. About the year 1763, it happened that the model of an atmospheric engine used at the lectures of Dr. Black, professor of natural philosophy in the university, required some

repairs, and it was accordingly placed in the hands of Watt. In the experiments which it became his duty to make with this model, he was struck with the fact that the quantity of steam consumed for each stroke of the piston was many times more than the contents of the cylinder. The large quantity of water necessary to be injected in order to complete the condensation also excited his surprise. This led him to make experiments, by which he soon arrived at the discovery of some of the most important phenomena connected with the evaporation of water. He made a near approximation to the proportion of the volume of steam to that of water. He ascertained with great precision the latent heat of steam, and consequently determined the quantity of water necessary to condense any given quantity of steam. Filled with astonishment at these results, and more particularly at the nature of latent heat, and at the great amount of the latent heat of steam, he repaired to Dr. Black, and communicated to him the results of his discoveries. He then, for the first time, learned Black's celebrated theory of latent heat, and found that he had himself thus accidentally discovered one of the most striking facts on which that theory rested.

Considering the atmospheric engine in an economical point of view, Watt was forcibly impressed with the waste and expense which appeared to arise in the unnecessary consumption of steam involved in its operation. In the theory of that engine, one cylinderful of steam ought to be sufficient for each stroke of the piston. Watt, on the other hand, found that the actual consumption was at the rate of four or five cylinderfuls per stroke. On examination, he discovered the source of this waste to arise from the fact that, in order to make the piston ascend, it was necessary not only to condense the steam, but to cool the whole mass of the cylinder down to 100°, while to make the piston descend, it was necessary not only to fill the cylinder with steam, but to raise the temperature of the cylinder and piston from 100° to 212°. He soon perceived that this enormous waste of fuel was the inevitable consequence of condensing the steam in the cylinder.

Reflection on these circumstances happily led him to the idea of condensing the steam in a separate vessel, which should be kept immersed in a cistern of cold water, and in which a jet of cold water might be kept constantly playing, with the addition of a pump to draw off the injected water and condensed steam from such vessel. In fact, all the details of the steam engine, as already described, were soon carried into practical effect, and engines constructed according to these principles. Instead of causing the piston to descend by the pressure of the atmosphere, as in the old atmospheric engine, it was forced down in Watt's engines by means of steam, and a lid was applied to the top of the cylinder through a steam-tight hole in which the piston rod passed to connect itself with the working beam.

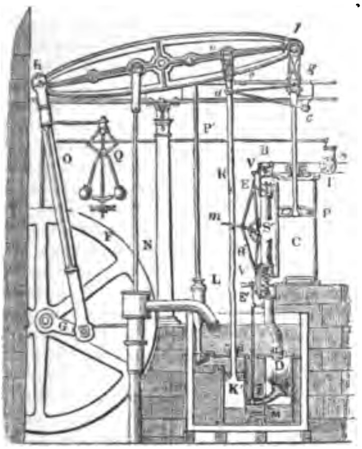
Single-acting Condensing Steam Engine.—When the steam engine is applied to the purpose of pumping water, which in the first periods of its invention was its only practical application, the force which it exerts is required only in raising the pump rods with their load of water, their own weight being more than sufficient for their descent. As the pump rods are attached to the end of a working beam hung upon an axis, the force of the steam is required to draw up that end by drawing down the end at which the steam piston is attached. The steam, therefore, being required only to press the piston downwards, is admitted above the piston, while the space in the cylinder below the piston is kept in free communication with the condenser. The operation of the valves by which the steam is admitted and withdrawn is precisely the same as in the double-acting engine, which will presently be described, and to which reference may be made for a fuller explanation of the action of the machine. When the piston has reached the bottom of the cylinder, the valves for admitting and withdrawing the steam being closed, a valve called the *equilibrium valve* is open, by which a free communication is made between the top and bottom of the cylinder: by this means the steam which fills the upper part of the cylinder, being allowed to flow equally to the lower part, will press with the same force on both sides of the piston, and will therefore have no tendency whatever to move it. Under these circumstances the preponderating weight of the pump rods suspended from the other end of the beam will draw the piston to the top of the cylinder. While it is ascending, the steam which was above will pass through the equilibrium valve below it; and when the piston has reached the top of the cylinder, the cylinder under the piston will be filled with the same steam which previously had driven the piston down. In order to accomplish the next down stroke, the equilibrium valve is closed, and the upper inlet valve and lower outlet valve are opened; the steam pressure acts above the piston, while a vacuum is produced below it, and the piston consequently descends.

Double-acting Condensing Steam Engine.—This species of engine, under some form or other, is that which is almost invariably used as a moving power in all manufactures in this country. One form of it, called a *beam engine*, represented in fig. 1, consists of a cylinder shown in section at C, in which a movable piston P is driven upwards and downwards by the force of steam supplied by a boiler placed near the engine. [STEAM BOILER.]

This piston gives motion to a *working beam* H*f*, which by means of a heavy bar O, called a *connecting rod*, moves a *crank* and *fly-wheel*, from which the machinery to be worked directly receives its motion. Steam is supplied from the boiler to the cylinder by the steam pipe S. The *throttle valve* T in that pipe, near the cylinder, is regulated by a system of levers connected with the *governor* Q. This governor is an apparatus consisting

of two heavy balls, attached to the ends of rods, which are kept revolving on a vertical shaft by a cord or band, or by a train of cogged

Fig. 1.



wheels connected with the fly-wheel. The velocity with which the balls of the governor revolve is therefore always proportional to that of the fly-wheel, and of the machinery driven by it. If, by reason of too rapid a supply of steam, an undue speed be imparted to the fly-wheel, the balls are whirled round with a corresponding velocity; and by reason of their centrifugal force they recede from the vertical spindle round which they turn, and acting thereby on the system of levers which connect them with the throttle valve T, they partially close the latter, check or diminish the supply of steam to the cylinder, and moderate the velocity of the machine. If, on the other hand, the motion of the engine be slower than is requisite, owing to a deficient supply of steam through S, then the balls, not being sufficiently affected by centrifugal force, fall towards the vertical spindle, and acting on the system of levers in the contrary way, turn the throttle valve T more fully open, admitting a more ample supply of steam to the cylinder, so as to increase the speed of the engine to the requisite extent.

The piston P is accurately fitted to the cylinder, and made to move in it steam tight by packing, with which it is surrounded. This piston divides the cylinder into two compartments, between which there is no communication by which steam or any other elastic fluid can pass. A case BB′ placed beside the cylinder contains the valves by means of which the steam which impels the piston is admitted and withdrawn as the piston commences its motion in each direction. The *upper steam box* B is divided into three compartments by two valves; above the upper steam valve V is a compartment communicating with the steam pipe S. Below the exhausting valve E is another compartment communicating with a pipe called the *eduction pipe*, which leads downwards from the cylinder to a vessel called the *condenser*, which we shall presently describe. By this eduction pipe the steam is withdrawn from the cylinder after it has driven the piston. By the valve V a communication may be opened or closed between the boiler and the top of the cylinder, so as to admit or intercept the supply of steam from the one to the other. By the valve E a communication may be opened or closed between the top of the cylinder and the condenser, so that the steam in the top of the cylinder may either be permitted to escape into the condenser or confined in the cylinder. The continuation S′ of the steam pipe leads to the *lower steam box* B′, which like the upper is divided into three compartments by two valves V′ and E. The upper compartment communicates with the steam pipe S′, and the lower with the eduction pipe. By means of the valve V′ steam may be admitted from the steam pipe S′ to the bottom of the cylinder, and by means of the valve E′ this steam may be permitted to escape to the condenser.

The four valves V, E, V′, and E′ are in the engine represented in the figure connected by a system of levers with a single handle or *spanner*, *m*, which being pressed upwards or downwards opens and closes the valves in pairs. Thus, when it is pressed *down*, the levers connected with it raise the upper exhausting valve E and the lower steam valve V′, and close the upper steam valve V and the lower exhausting valve E′. On the other hand, when the spanner *m* is pressed *up*, it opens the upper steam valve V and the lower exhausting valve E′, at the same time closing the upper exhausting valve E and the lower steam valve V′.

The cylinder is closed at the top, and the piston rod P, being accurately turned, runs in a steam-tight collar furnished with a stuffing box, by means of which it is surrounded by a packing of hemp, and constantly lubricated with melted tallow. A funnel is screwed on the top of the cylinder, through which, by opening a stop-cock, melted tallow is permitted to fall from time to time on the piston, so as to lubricate it.

The condenser D is submerged in a cistern of cold water: at its side there enters a tube I′, governed by a cock I, which being opened or closed to any required extent, a jet of cold water may be allowed to play in the condenser. This jet throws the water upwards towards the lower orifice of the eduction pipe L′. From the bottom of the condenser D proceeds a tube having a valve M in it opening outwards; this tube leads to the *air pump* K′, which is a pump submerged in the same cistern with the condenser, worked by a piston having a valve in it opening upwards. The piston rod R of the air pump is carried upwards, and attached at *d* to a system of jointed rods called the *parallel motion*, to which is also attached at *g* the great steam piston-rod. On the rod of the air pump are placed projecting pins, which, as it alter-

nately ascends and descends, strike the spanner *m*, and thereby open and close the valves V, V′, E, E′, in pairs, as already described.

The upper part of the air-pump cylinder communicates by a valve opening outwards with a small cistern K, called the *hot well*, for a reason which will presently appear. A pump L, called the *hot-water pump*, descends into the hot well, and is worked by the great working beam to which its rod is attached.

If the machine thus arranged were worked for any great length of time, the cistern of water in which the condenser and air pump are immersed would become warm, and the condenser would be rendered incapable of doing that for which it is alone useful, viz. of reducing the steam to water *by cold*. To prevent this, a pump N is provided, called the *cold-water pump*, by which a supply of cold water is constantly kept flowing into the cistern, the heated water being at the same time allowed to escape by a waste pipe. The temperature of the water in the cold cistern is thus kept so low as to be capable of effectually condensing the steam.

The piston being supposed to be at the top of the cylinder, the spanner *m* will be raised by the lower pin on the air-pump rod, and the valves V and E′ will be opened, and at the same time the other pair of valves V′ and E will be closed. Steam will therefore be admitted above the piston, and the steam which had previously filled the cylinder below the piston will be drawn off to the condenser. It will there encounter the jet of cold water, which is kept constantly playing there by keeping the cock I sufficiently open. It will thus be immediately reduced to water, or condensed [STEAM], and the cylinder below the piston will remain a vacuum. The steam, therefore, admitted from the steam pipe through the open valve V to the top of the cylinder will press the piston to the bottom of the cylinder. As it approaches that position, the spanner *m* will be struck downwards by the upper pin on the air-pump rod, and the valves V and E′, previously open, will be closed, while the valves V′ and E, previously closed, will be opened. The steam which has just pressed down the piston, and which now fills the cylinder above the piston, will then flow off through the open valve E by the eduction pipe to the condenser, where it will be immediately condensed by the jet of cold water which constantly plays there; and steam from the boiler, admitted through the open valve V′, will fill the cylinder below the piston, and press the piston upwards. When the piston has reached the top of the cylinder, the lower pin on the air-pump rod will have struck the spanner *m* upwards, and will thereby have closed the valves V′ and E, and opened the valves V and E′. The piston will then be in the same situation as at the commencement, and will again descend, and so will continue to be driven upwards and downwards by the steam.

While this process is going on in the cylinder, a quantity of warm water is formed in the condenser, by the mixture of condensed steam with the cold water admitted through the condensing jet I′. It has been shown [STEAM] that any quantity of water in the state of steam, being condensed by cold water, will raise nearly six times its own weight of cold water from the freezing to the boiling point by the latent heat which is rendered sensible in the process of condensation. But since the jet of cold water, instead of being at the temperature of melting ice, is at the common temperature of the atmosphere, say 50°, and it is necessary to reduce the temperature of the condenser to at least 100° (otherwise steam would be produced by it, which would seriously resist the motion of the piston), and to reduce water from 212° to 100° by mixture with water at 50° would require of the latter a quantity equal to about twice the former, it follows that the quantity admitted through the jet must be more than twenty times greater than that which passes through the cylinder in the form of steam.

The warm water thus formed in the condenser, if allowed to accumulate there, would soon choke it up and stop the action of the machine. To prevent this, the air pump is provided; when the air-pump piston ascends, it leaves below it a vacuum, and the *foot valve* M being relieved from all pressure, the weight of the water in the condenser forces it open, and the warm water flows from the condenser into the lower part of the air pump, from which its return to the condenser is prevented by the closed valve. When the air-pump piston descends, its pressure on the liquid under it will force open the valve, through which the warm water will pass; and when the piston descends to the bottom of the pump barrel, the warm water which was below it will pass above it, and cannot return, as the valves which open upwards will be kept closed by its weight. When the piston next ascends, it will raise the water thus collected above it, and will throw it through the valve into the hot well K.

The hot-water pump L is usually a suction and forcing pump, and draws up the warm water from the hot well, driving it through a pipe called the *feed pipe* to a cistern placed over the boiler, from which the boiler derives its feed of water. [STEAM BOILER.]

The system of jointed rods *c d e f g*, called the *parallel motion*, has for its object the maintenance of the rods of the steam piston and air pump in a truly vertical position. The steam piston-rod imparts motion to the beam, and the air-pump rod receives motion from it. But as the beam moves alternately upwards and downwards on an axis, every point on it must move alternately in the arc of a circle whose centre is in the axis of the beam. If, then, the ends of the rods of the steam piston and air pump were attached immediately to the beam, they would move not in truly vertical straight lines, but in the arcs of circles, and by reason of the curvature of such

arcs they would be alternately reflected to the right and to the left. Such an effect would be quite incompatible with that smoothness and precision which are essential to the effective action of the steam engine. By the parallel motion the ends of these piston rods are not immediately attached to the working beam; a rod *c d* called the *radius rod* moves on a fixed centre *c* attached to the framing of the engine; a bar *d b* connects the other end of this radius rod with a pivot *b* on the beam, so that as the beam ascends and descends the pivots *b* and *d* each move in an arc of a circle, and these pivots are thereby drawn aside, but always in contrary directions. These deflections of the ends of the bar *d b* are neutralised at its middle point *e*, which deviates neither to the right nor to the left, but moves in a vertical straight line. To this point *e* the end of the air-pump piston is attached.

At the end of the beam to another joint *f* is attached a bar *f g*, equal to *b d*, connected by pivots with another bar *d g* equal in length to *b f*, so as to form the jointed parallelogram *b d g f*. By this arrangement, as the beam ascends and descends, the point *g* is moved in a manner altogether similar to the point *e*, only that it moves through a greater space in the proportion of the distance of *g* from the axis of the beam to that of *e* from the same point. The point *g*, therefore, to which the steam piston is attached, is moved upwards and downwards in a truly vertical straight line, while the end *f* of the beam with which it is connected is moved upwards and downwards in the arc of a circle.

When the piston is at the top of the cylinder the crank G placed on the axis of the fly-wheel F is at its lowest position, and when the piston is at the bottom of the cylinder it is in its highest position. In each of these positions the action of the steam on the piston could not impart any motion to the crank; for the connecting rod O being then in line with the crank, any force given to it, being necessarily exerted in the direction of its length, would only produce a pressure or strain on the crank pin without the least tendency to turn the crank round the axis of the fly-wheel. In these positions the machine is therefore placed in a dilemma, in which the moving power ceases to have any influence on the object which it is intended to move.

The machine is extricated from this dilemma by the inertia of the fly-wheel. That wheel is a large mass of matter, which, having once received a certain velocity of rotation on its axis, has a tendency to retain such motion, and will, in fact, retain it until it has been deprived of it by the continued resistance of friction and the air. When, therefore, the crank arrives at either of the positions above mentioned, and the moving power ceases to be effective, the inertia of the fly-wheel causes it to continue its motion, and the crank is immediately turned out of the extreme position which it had assumed, and thrown into a position in which the power of the piston on it becomes effective.

The functions of the fly-wheel are, however, not confined to carrying the machine thus through the dead points by the energy of the force received from the piston when the crank was in a more favourable position; it likewise equalises by the same property the unequal effect of the crank. It is only when the crank forms a right angle with the connecting rod that it is fully effective, and as that angle changes, its leverage changes, until at length it is reduced to nothing at those extreme positions just mentioned. When the crank is in and near the position in which it is rectangular to the connecting rod, its action is shared between the fly-wheel and the machinery driven by the engine, a part being engaged in accelerating and therefore giving momentum to the fly-wheel. As it passes towards the dead point, this momentum taken up by the fly-wheel is given back to the crank in aid of the moving power, at those positions of the crank where the effect of the moving power upon it becomes enfeebled. In this manner the fly-wheel in the steam engine becomes a perfect equaliser of the mechanical action of the machine.

To the working end H of the beam is attached the *connecting rod* O, formed of cast iron, the lower end of which is attached to the crank G by a pin. On the axis of the crank is placed the fly-wheel, and connected with its axle is the governor Q already described. The manner in which the crank affects the connecting rod at the dead points produces an effect of great importance in the operation of the engine. When the crank approaches the lowest point of its play, and at the same time the piston is approaching the top of the cylinder, the motion of the crank pin becomes nearly horizontal, and consequently its effect in drawing the connecting rod and the end of the beam downwards, and the piston upwards, is extremely small. The consequence of this is, that as the piston reaches the top of the cylinder its motion becomes very rapidly retarded; and as the motion of the crank pin at its lowest point is actually horizontal, the piston is brought to a state of rest by this gradually retarded motion. A similar effect is produced at the other dead point. The motion of the engine is consequently very smooth, and free from shocks and jerks, the occurrence of which would materially impair its durability and its eligibility as a prime mover.

Such, then, is the engine of Watt. Notwithstanding the manifest advantages attending these improvements, the mining and manufacturing interests were slow and reluctant in adopting them; and, at the end of twenty years from the date of his first improvement, Watt and his partners found that the manufacture of the steam engine, far from being a source of commercial profit,

had entailed upon them a loss of capital to the amount of about 50,000*l*. An application was made to parliament, on this ground, for an extension of the patent, which, after much opposition, was granted till the year 1800. Various improvements in the more minute details of the machinery of the engine succeeded this; and Watt lived to reap an ample reward for his ingenuity and perseverance, and to be acknowledged as one of the greatest benefactors of the human race.

The engine, as applied to drainage and to manufactures, has received no important improvement in its principle since it was dismissed from the hands of Watt. Those principles which he suggested and applied have been carried out to their fullest extent, and the efficiency of the engine has been thus proportionally increased. Modern engines, it is true, as applied to manufacturing purposes, are very different in some of their details from the form of engine just described. For example, the valves, instead of being moved by means of pins or tappets upon the air-pump rod, are now moved by an eccentric; and sliding or sluice valves are now very generally used. Sometimes the beam is discarded altogether, and in the construction of the parts malleable iron is now much more largely employed. But all these modifications merely affect the detail; and anyone who perfectly understands the operation of Watt's engine will have no difficulty in understanding the mode of action of any other variety of engine that has been introduced since his time.

Expansive Engine.—As the operation of the steam engine has been explained, we need only remark that the power which moves the piston is the immediate force with which vapour is produced in the boiler. Each quantity of water which is successively evaporated obtains the space requisite for it in the form of steam, by pressing towards the cylinder an equal quantity of steam previously contained in the boiler; and it is the force with which the steam is thus pressed forward that impels the piston. But it has been shown [STEAM] that great additional mechanical power will be obtained from the steam, if, besides this moving force, which results from immediate evaporation, the expansive power of the steam separated from the water be used. This is accomplished by closing the valve through which steam flows from the boiler to the cylinder before the piston has completed its stroke. Thus, let us suppose that when the piston has advanced through half its stroke the steam valve be closed. The steam which is then acting upon the piston will still urge it forward; but as the piston advances, this steam, assuming a proportionally augmented volume, will acquire a gradually diminished pressure, so that through the remaining half of the stroke the piston will be urged by a pressure progressively decreasing, and at the termination of the stroke it will be a little less than half the force with which the piston was impelled while the steam valve was open.

Since the force of the steam from the moment the steam valve is closed is thus continually diminished, its moving power might be so much attenuated that it would be incapable of overcoming the resistance so as to complete the stroke; this would happen if the steam were cut off when only a small fraction of the stroke has been made, unless the pressure of the steam while the valve is open exceeds the resistance in a proportionate degree. It is for this reason that the expansive principle cannot be brought into operation to any considerable extent, unless steam be used of a greater pressure than is commonly adopted in low-pressure engines. It is also apparent that to produce the same power either a greater volume of cylinder, or greater velocity of motion, must be given when the expansive principle is used.

The mechanism by which the expansive principle is brought into practical operation consists merely in the adaptation of valves or slides which shall stop the admission of steam when the required fraction of the stroke has been made by the piston, but which shall leave the communication with the condenser open till the stroke is completed. If separate valves be used, this is accomplished by adapting the pins or other mechanism by which they are worked to open and close them independently of each other at the proper times. If slides be used, it is effected by regulating the form and movement of the slide, so as to cover and uncover the passages to the cylinder at the proper times. Each species of valve, and each form of slide or cock, has its own peculiar provisions for accomplishing this.

At the time of this invention the steam engine had never been used, except for the purpose of raising water. It became a substitute for horse-power in working pumps. Although Watt perceived, in the first instance, the ease with which it might be adapted as a general moving power, his first efforts were to get it adopted in the mining districts for drainage. His first engines were, accordingly, single-acting or pumping engines; and it was not until the year 1782 that he took a patent for the double-acting engine, the structure and mode of action of which have now been described.

Cornish Engines.—The Cornish pumping engines are for the most part single-action engines. They are constructed of enormous power, and carry out the expansive principle to a great extent. In Cornwall, engines are used for the drainage of mines with cylinders from 7 to 8 feet in diameter, and from 10 to 12 feet stroke. Steam having a pressure of from 20 to 50 lbs. per square inch, and upwards, is used for impelling them, and is cut off at a third, a fourth, and sometimes even at a twelfth, of the stroke. A system of careful inspection has been for some years established by the mining companies, with a view to improving the efficiency of the engines, and

monthly reports of the performance of the engines have been regularly printed. The effect of this has been to stimulate the activity and skill of all concerned in the manufacture and working of these machines, and a marked improvement in them has taken place. The efficiency of these engines is estimated by the number of pounds weight of water which they are capable of elevating one foot high by the combustion of a bushel of coals. This has been termed the *duty* of the engine. In 1769, when Watt first directed his attention to the steam engine, Smeaton computed that the average duty of the engines then in use was about 5½ millions; from that time to the year 1800, a period of thirty years, the duty, owing to the improvements made by Watt, was gradually increased to 20 millions, or very nearly quadrupled. In 1813, the system of inspection just mentioned was commenced, and the average duty was the same as in 1800. From this time to 1826, the engines underwent a progression of slow but steady improvement, and the duty was increased to 30 millions. In 1828, the average duty had risen to nearly 37 millions. The increase since that time has been slower: the average duty for the last few years has been from 60 to 70 millions; but in one well-conducted experiment it was found that by the combustion of a bushel of coals an amount of mechanical power was produced which raised the inconceivable load of 125 million pounds weight one foot high. Thus, by the improvements of Watt and their immediate consequences, the power of the steam engine was, within the space of seventy years, increased about 25 fold. Even this large performance, however, does not exhaust the power resident in the heat produced by the combustion of the coal burnt, and it is now known [THERMODYNAMICS] that even in the best Cornish engines about nine-tenths of the heat is lost without producing any useful effect.

Non-condensing Steam Engines.—The form and structure of non-condensing engines differ from those of double-acting condensing engines only in the absence of the condensing apparatus; i.e. the condenser, the air pump, and the cold-water pump. The steam, after it has impelled the piston, instead of being conducted to a cold vessel to be condensed, is simply allowed to escape into the atmosphere, and is commonly ejected into the chimney of the furnace.

The operation of such a machine is extremely simple. The valves by which the steam is admitted to, and allowed to escape from, the cylinder, are exactly similar to those of the double-acting engine. In the down stroke of the piston, the upper steam valve being open admits steam from the boiler above the piston, and the lower exhausting valve allows the steam below it to escape through a tube into the atmosphere. It is evident that, in such a machine, the piston is always resisted by the pressure of the escaping steam. As such escape cannot be effected except by steam of greater pressure than that of the atmosphere, it follows that the piston is always resisted by a force somewhat greater than the atmospheric pressure. The steam which urges the piston is therefore effective only by the excess of its pressure above that of the escaping steam; and hence the more economical course in non-condensing engines is to employ steam of as high a pressure as may be convenient—the counteracting pressure of the atmosphere being relatively smaller in such a case. All locomotive engines are non-condensing, and the waste steam is invariably projected up the chimney, thus greatly increasing the intensity of the draught.

As the steam used in non-condensing engines must, of necessity, have a pressure considerably exceeding that of the atmosphere, such machines have been generally called *high-pressure engines*; while those which condense the steam have, on the other hand, been called *low-pressure engines*. These terms fail, however, to express correctly the nature of these engines respectively. Many engines in which condensation is used, especially those in which the expansive principle is applied with much effect, are worked with steam of a high pressure, not unfrequently with a pressure amounting to from two to three atmospheres. It is therefore not correct to call such machines low-pressure engines. It is, however, true that engines worked without condensation must, of necessity, be worked by steam of a pressure which is generally called *high pressure*.

Rotatory Steam Engine.—This term is applied to an engine in which a motion of rotation is produced immediately by the action of the steam, without the intervention of such mechanism as the working beam, crank, and fly-wheel. This is usually effected by a piston which, instead of moving longitudinally in the cylinder, revolves within the cylinder on an axis which coincides with the geometrical axis of the cylinder itself. The mechanism is so contrived that this piston shall revolve in steam-tight contact with the sides and ends of the cylinder; and that while steam from the boiler constantly presses it on one side, the steam on the other side shall continually escape to the condenser if it be a condensing engine, or to the chimney if it be a non-condensing engine—a movable division of some kind or other being necessarily interposed between the steam and vacuum to enable this to be done. Most of the contrivances for rotatory engines which have been suggested differ one from the other only in the mechanical expedients by which these ends are attained. Such machines are very numerous and various; but as none of them have yet been found sufficiently advantageous to force them into any use beyond the experimental trials of their inventors, it is sufficient here to have indicated the general principle of their structure.

Marine Engines.—The manner in which the steam engine is rendered an instrument for the propulsion of vessels must, in its general

features, be so familiar to everyone as to require but short explanation. In the case of paddle vessels, a shaft is carried across the vessel, being continued on either side beyond the sides; to the extremities of this shaft, on the outside of the vessel, are attached a pair of wheels, constructed like under-shot water wheels, having a number of flat boards called *paddle boards* fixed upon their rims. As the wheels revolve, these paddle boards strike the water, driving it in a direction contrary to that in which it is intended that the vessel shall be propelled. The moving force imparted to the water thus driven backwards, by reaction on the vessel propels it. On the paddle shaft are fixed two cranks, placed at right angles one to the other, so that whenever one of them is thrown into the highest or lowest position the other is horizontal. These cranks are worked by strong iron rods called *connecting rods*, which are themselves either driven directly by the pistons of two steam engines, or are worked by beams moved by those pistons. Thus the medium of working becomes similar to that used in the ordinary land engines. The two cranks being placed at right angles, it follows that when one piston is at top or bottom of its stroke, and the crank is driven by it into the highest or lowest position, the other will be at the middle of its stroke, and the crank driven by it will be in the horizontal position. One of the pistons is therefore always in a position to produce the most advantageous effect on the crank at the moment that the other piston loses all power over the crank driven by it; and in the same manner it may be seen that while the power of one piston is augmented from zero to its greatest effect, the power of the other is decreasing from its greatest effect to zero. Thus the combined action of the two pistons is nearly uniform in its efficiency. If one engine only were used the motion of the wheels would be unequal, being most rapid when the piston is at the middle of the stroke, and slowest at the extremities. Nevertheless, single engines are sometimes used in paddle vessels with good effect. In the case of screw vessels, the action of the engines is similar, but the propelling shaft runs fore and aft above the keel, and protrudes at the stern, where a great screw propeller is hung upon it. [SCREW PROPELLER.]

The steam engines used for navigation may be either condensing engines or non-condensing engines. If the latter are employed, steam must be used having a pressure above the atmosphere of from 50 to 80 lbs. per square inch. Boilers in which steam is produced under this pressure are considered in Europe so unsafe, that non-condensing engines with low-pressure boilers are almost universally used for navigation. In America, however, high-pressure boilers with non-condensing engines are extensively used on some of the rivers.

The arrangement of the parts of marine engines is different in several respects from land engines. Steam vessels being generally employed to navigate the open seas, and being, therefore, subject to the vicissitudes of tempestuous weather, the machinery must be protected by being placed below the deck. The space allotted to it being thus limited, great compactness is necessary. In paddle vessels, the paddle shaft being very little below the deck, the working beam and connecting rod could not be placed so conveniently above it. If a beam engine, therefore, be employed, two beams are so placed that one comes on each side of the cylinder, and is driven by the piston by means of a cross head attached to the piston rod, from the ends of which rods, called *side rods*, are carried downwards to the ends of the beams. From the other ends of the beams the connecting rod is presented upwards towards the crank. In screw vessels the engines are mostly made with the cylinders horizontal, or if vertical they are usually inverted, and work down to cranks on the screw shaft. [SCREW PROPELLER.]

Side-Lever Engines.—One form of marine engine formerly in the most extensive use, and still employed in many paddle vessels, is the side-lever engine. But the oscillating engine has nearly superseded it. The general arrangement of the parts of a side-lever engine will be easily understood by reference to fig. 2, in which is represented in section a side-lever marine engine with a flue boiler, as placed in a steam vessel. The sleepers supporting the engine are represented at X, and the base of the engine is secured to these by bolts passing through them. S is the steam pipe leading from the steam chest in the boiler to the slides *c*, by which it is admitted to the top and bottom of the cylinder. The condenser is represented at B, and the air pump at E. The hot well is seen at F, from which the feed is taken from the boiler. L is the piston rod connected with the beam H, working on a centre K, near the base of the engine. The other end of the beam H drives the connecting rod M, which extends upwards to the crank, which it works upon the paddle shaft O; *a a* are the rods of the parallel motion. The framing by which the engine is supported is represented at Q R.

The beam exhibited in the figure is shown in dotted lines, as being on the farther side of the engine. A similar beam, similarly placed, and moving on the same centre, must be understood to be at this side, connected with the cross head of the piston in like manner by a parallel motion, and with a cross tail attached to the lower end of the connecting rod and to the opposite beam. The eccentric which works the slides is placed upon the paddle shaft O: and the connecting arm which drives the slides may be easily detached when the engine requires to be stopped. The section of the boiler grate and flues is represented at W U. The safety valve *y* is enclosed beneath a pipe carried up beside the chimney, and is inaccessible to the engine-man. The cocks for blowing out the salt water from the boiler (a process explained under the head STEAM BOILER) are represented at *h*, and the feed pipe at I.

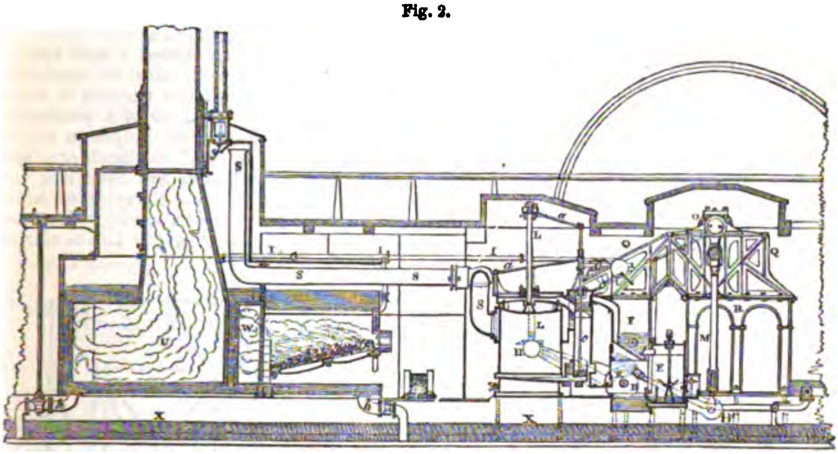
The nature and operation of the several parts

just mentioned will be understood by reference to the explanation of the structure and operation of the double-acting land engine, for, in fact, the marine engine, as here represented, is nothing more than a double-acting condensing steam engine, adapted in its form to the circumstances in which it is used in navigation.

Since, however, the double-acting land engine, which has been described, is not provided with a slide valve worked by an eccentric, it will be proper to explain the form and mode of action of those important parts of the machine.

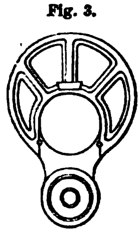
An eccentric is a disc of metal perforated with a hole for the reception of the crank shaft; but this hole is not in the middle of the disc. The edge of the disc is encircled by a ring of brass, from which a rod proceeds to the connections of the slide valve, and it will be obvious that by the revolution of the shaft this rod will be drawn backwards and forwards, in

Fig. 2.



the same manner as if it were connected with a crank in the shaft. An eccentric, indeed, is virtually a short crank with a very large crank pin; and a crank of the same length as the distance from the centre of the shaft to the centre of the disc which constitutes the eccentric would give precisely the motion imparted by the eccentric itself. One form of eccentric employed in steam vessels is represented in fig. 3. A balance-weight is applied opposite to the heavy part of the eccentric, in order that the eccentric may stand in any position on the shaft; and a projecting piece of metal is fixed upon the shaft, which, when it comes in contact with a similar piece of metal upon the eccentric, carries the eccentric round with the shaft. If it should be necessary to reverse the engine, there is another piece of metal upon the opposite side of the shaft, which also comes into contact with the stop upon the eccentric, and the projecting side of the eccentric then stands upon the opposite side of the shaft, as it must in order to communicate a reverse motion to the valve. In modern engines two eccentrics with a link connecting the ends of the two eccentric rods are commonly used for giving motion to each valve. One of these eccentrics is set for moving ahead and the other

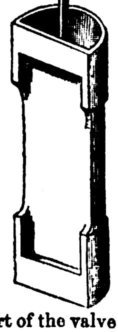
Fig. 3.



for moving astern, and by moving the link endways the valve is made to partake of the motion of that eccentric which is contiguous to it. By this apparatus the engine may be started, stopped, or reversed merely by shifting the position of the link with reference to the valve rod.

The species of valve usually employed in side-lever marine engines is the D valve, so called because it is half a cylinder, and its cross section therefore resembles the letter D. Of this species of valve there are two varieties, the long D and the short D. In the long D the waste steam escapes from one of the ports of the cylinder through the centre of the valve. In the short D there is no central passage in the valve, but the valve consists of two short and closed portions connected together by one or more rods. The long D valve has been most generally adopted. A valve of this kind is represented in fig. 4. The flat projecting part of the valve moves upon similar flat parts on the front of the cylinder, and when the valve is in the middle of its stroke the flat projecting portions accurately close the ports or passages by which the steam enters and leaves the cylinder. The round part of the valve opposite to each cylinder port is made tight by the application of a hemp packing, placed in the

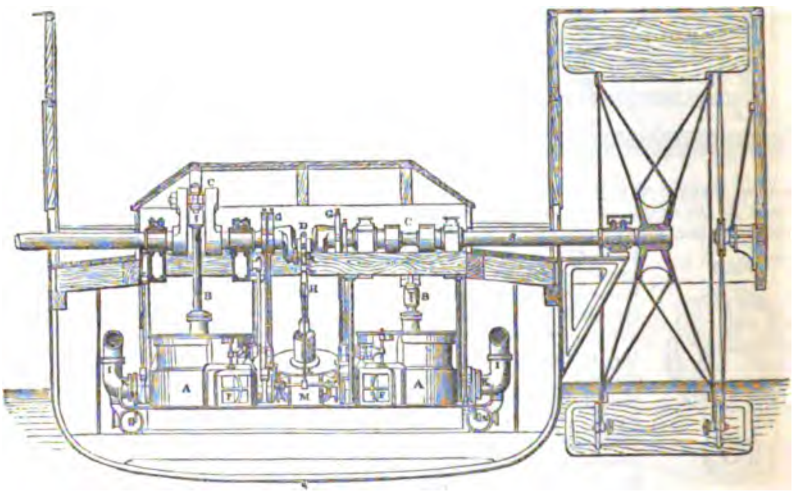
Fig. 4.



casing by which the valve is surrounded; and between the upper and lower packing steam is admitted to circulate round the valve—the steam pipe from the boiler having its debouche in the valve casing. If now the valve be in its middle position, so as to cover accurately both of the cylinder ports, it will be clear that if it be drawn upwards steam will be allowed to enter from the valve casing above the piston; and at the same time any steam or vapour will be allowed to escape from beneath the piston into the central part of the valve, which communicates with the condenser by means of a pipe penetrating the valve casing, either above the upper packing or beneath the lower packing. If the valve be forced below its middle position, the contrary operation will be produced. By moving the valve up and down, therefore, which is done by the eccentric, the piston is pressed up and down in the cylinder in the manner required.

Oscillating Engine.—Side-lever engines occupy an inconvenient amount of space in steam vessels, and also exhibit a needless complication of parts. The strain has to be transmitted not merely through the piston rod and crank shaft, but also through the cross head and cross tail, side rods and connecting rod, and the side levers or beams. This multiplication of the moving parts obviously increases the risk of fracture, and the side levers themselves are peculiarly susceptible of accident from this cause, since by the properties of a lever of this class, the stress or strain upon the beam at the main centre or pivot is twice as great as the strain upon the piston. These defects of the side lever engine have caused a new species of engine to be introduced, called the *oscillating engine*, because the cylinder vibrates or oscillates somewhat in the manner of a pendulum. In this engine the top of the piston rod is coupled immediately with the crank pin, and as the piston rod moves up and down in a line coincident with the axis of the cylinder, while the crank pin revolves in a circle, it is necessary that the cylinder should be able to vibrate

Fig. 5.

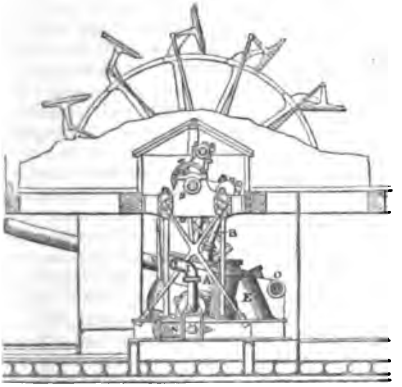


laterally, to enable the motions of the piston rod and crank pin to be reconciled with one another. The cylinder is consequently provided on each side with a short hollow pivot, or trunnion, on which it swings: and through one of these trunnions the steam enters the cylinder from the boiler, while through the other the steam escapes from the cylinder to the condenser. The alternate introduction of the steam above and below the piston is governed by a slide valve attached to the cylinder, and swinging with it; or, in large engines, two valves may be employed for this purpose, and by their suitable attachment to the cylinder they will balance one another.

In steam vessels in which oscillating engines are employed, the cylinders are set immediately beneath the cranks, and the engines occupy but little more in the length of the vessel than the diameter of the cylinder. In the shaft which connects the engines together, and which is called the *intermediate shaft*, a crank is forged, and this crank in its revolution gives motion to the pistons of one or more air pumps. The general nature of the arrangements at present employed in vessels of the most improved class, will be readily understood by a reference to fig. 5, which is a transverse section of the steam yacht Peterhoff, constructed for the emperor of Russia by Messrs. Rennie; and to fig. 6, which is a side view of the engines of the same vessel. A A are the cylinders; B B are the piston rods which are connected immediately with the cranks C C; D is a crank in the intermediate shaft, for working the piston bucket of the air pump E; F F are the slide valves

by which the admission of the steam to the cylinders is regulated; G G are double eccentrics on the intermediate shaft, whereby the valves F F are moved. The purpose of the double eccentrics is to enable the link motion to be employed. H is a handle by which the engines may be stopped, started, or reversed. I I are the steam pipes leading to the steam trunnions K K, on which, and on other trunnions connected with the pipe M, the cylinders oscillate. N N are pumps, the pistons of which are attached to the trunnions, and are worked by the oscillation of the cylinders. O is the

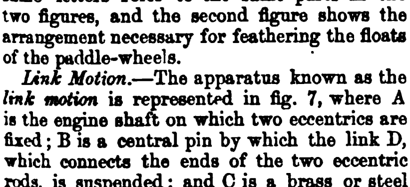
Fig. 6.



waste-water pipe, through which the water which has accomplished the function of condensing the steam is ejected overboard. The same letters refer to the same parts in the two figures, and the second figure shows the arrangement necessary for feathering the floats of the paddle-wheels.

Link Motion.—The apparatus known as the *link motion* is represented in fig. 7, where A is the engine shaft on which two eccentrics are fixed; B is a central pin by which the link D, which connects the ends of the two eccentric rods, is suspended; and C is a brass or steel block which may be moved freely from end to end of the slot in the link D. The centre of this block carries a pin which connects with

Fig. 7.



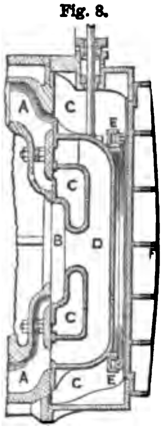
Link Motion.

the valve rod of the engine, and by raising or depressing the link, which is done by means of a suitable rod attached at the point B, the end either of the upper or lower eccentric rod is brought opposite to C, and imparts to the valve the motion of the eccentric to which the block C is opposite. If the link be raised only enough to bring the block C to the middle of the link, there will be no motion imparted to the valve, and the engine will therefore stop; whereas if C be brought to one end of the link the engine will move ahead, and if brought to the other end the engine will move astern. By working the engine with the block C at a short distance from the end of the link, the engine, if constructed with a little overlap on the valve, will be worked more expansively; for as the extent to which a given amount of lap on the valve influences the cutting off of the steam varies with the throw of the valve, to reduce the throw with a given lap is tantamount to an increase of the lap with the same throw.

Gridiron and Equilibrium Valves.—The increasing size of steam engines, especially as applied to steam navigation, and the increased difficulty of moving valves of great size by hand to start the engines, together with the need of rapid motion, have pointed to the necessity of some modification of the older forms of slide valve by which these qualities would be realised. The D valve has consequently been so modified in its construction as to take the pressure of the steam off the back of it. This is accomplished by introducing a packing opposite to the upper part of the cylinder port, and another opposite to the lower part. The pressure on the back of the valve is thus made the same as the pressure on the front, and the resistance due to the friction of the packing is the only force that has to be overcome. The form of valve employed in locomotives, and hitherto much used in oscillating and other engines, is the three-ported valve, in which the upper and lower ports or passages leading to the cylinder, and a central port—communicating with the condenser in condensing engines, and with the atmosphere in high-pressure engines—are covered by a box with its open side against the cylinder, on which it is capable of moving steam-tight. But the length of the box is not sufficient to cover the whole three ports, but only one of the end ports and the central one. The box is set in a casing, and is surrounded by steam leading from the boiler; and the effect of moving up and down the box within the casing is to place each end of the cylinder alternately in connection with the boiler and with the atmosphere or condenser. This valve answers admirably for small engines, but the travel of the valve, which should be equal to the depth of the port, is too great to be convenient in the case of large engines moving at a high speed; and, further, the pressure of the steam against the bottom of the box is so great when acting over a large surface as to create an amount of resistance from friction that is not easily overcome. To remedy these defects, the gridiron and equilibrium forms of valve have been introduced. In the gridiron valve each port is divided into a number of narrow ports, by which the travel of the valve may be correspondingly abridged. In the equilibrium valve a ring is applied to the back of the valve, which rubs steam-tight against the

back of the valve casing. The interior of this ring communicates with the atmosphere or the condenser accordingly as the engine is a high-pressure or a condensing one, and by this expedient an equilibrium of pressure is established between the back and front of the valve, which discharges the friction and enables the valve to be moved with facility. In engines of large size, both of these expedients are generally introduced, as will be seen by a reference to fig. 8, which is a longitudinal section of part of one of the cylinders and of one of the valves of the screw engines of the steamer Great Eastern. Here A A are the cylinder ports, each of which is split into two narrow ports before reaching the valve face; B is the central port or passage leading to the condenser; C C C C are portions of the valve casing, which is filled with steam, and D is the valve which, as represented, is opening the upper ports to the steam, while the lower ports are open to the condenser; E is a ring fixed on the back of the valve, and moving with it, which rubs on the door which constitutes the back of the valve-casing. A small hole is bored through the back of the valve, so as to enable the space within the ring to communicate with the exhaust passage B, by which expedient the pressure of the steam is taken off the back, and the valve is rendered easily movable.

Fig. 8.



Gridiron Equilibrium Valve.

Starting Cylinders and Valves.—In some large marine engines, small cylinders have been introduced to move the link motion by which the movements of the valves of the main engines are controlled. In other cases, starting valves have been introduced. Both expedients were first applied by Mr. Bourne, the first in 1836, and the second in 1852.

Feathering Paddle-wheels.—In one variety of paddle-wheel, the float-boards which act upon the water are fixed in a radial position, like the buckets of an under-shot water-wheel, as has already been explained; and this species of wheel is largely employed both in the case of river and sea going vessels. Latterly, however, paddle-wheels with movable floats, of the kind represented in the preceding engravings, have obtained a marked preference, and vessels fitted with such wheels are found to realise a considerably increased speed. It will be remarked, that each float is hung upon an axis, whereby the inclination at which it enters or leaves the water may be altered; while by means of levers which are attached to the floats, and acted upon by rods converging to a centre eccentric to the shaft, a feathering motion is imparted to the floats by the revolution of the wheel. In river vessels the use of feathering wheels enables a small diameter of wheel to be employed without loss from angular impact; and with wheels of a small diameter, the engines may be worked with a greater speed, and will thus exert more power. In the case of sea-going vessels the diameter of the paddle-wheels cannot be materially reduced, whatever species of wheel is employed; for if the wheels were made very small, they would be immerged to the centre, or be out of the water altogether, if the sea should become boisterous: nevertheless, feathering wheels are advantageous in the case of ocean vessels also, as they act more beneficially than common radial wheels when deeply immersed, and with variable immersions, therefore, they maintain a greater average efficiency. There are objections, however, incident to the use of feathering wheels, which go far to balance these advantages. They are expensive both to make and to maintain. The wear and friction in such a multitude of joints is very considerable; and if any of the arms get adrift, or break, they will be whirled round like a flail, and may perhaps cut through the paddle box or even through the vessel. If the injury be of such a nature that the wheels cannot be turned round (and this has sometimes happened), it will follow that the engines will be virtually disabled until the obstruction can be cleared away; and if the weather be very stormy, or the vessel be in a critical situation, she may be lost in consequence of her temporary derangement. Nevertheless, feathering paddle-wheels have been on the increase in paddle vessels, and to diminish the risk of accident they are made very strong and sometimes of steel. The bearings and pins are usually made of iron covered with brass, and the eyes of the joints are lined with brass or, better still, with lignum vitæ or African oak.

Proportions of Marine Engines.—In oscillating engines the piston rod is usually made one-ninth of the diameter of the cylinder, and the crank pin is made about one-seventh of the diameter of the cylinder. The diameter of the paddle shaft must have reference not merely to the diameter of the cylinder, but also to the length of the stroke of the piston, or, what is the same thing, to the length of the crank. If the square of the diameter of the cylinder in inches be multiplied by the length of the crank in inches, and the cube root of the product be extracted, then that root multiplied by ·242 will give the diameter proper for the shaft in inches at the smallest part. The diameter of the trunnions is regulated by the diameter of the steam and eduction pipes, and these are each usually about one-fifth of the diameter of the cylinder; but it is better to make the steam trunnion a little less, and the eduction trunnion a little more, than this proportion. The steam and eduction pipes, where they enter their respective trunnions, are kept tight by a packing of hemp, which is compressed by a suitable ring or gland, tightened by screws. In land engines, the air pump and condenser are each made about one-eighth of the capacity

of the cylinder, but in marine engines they are made somewhat larger.

Proportions of Paddle-wheels.—The diameter for the paddle-wheel of a steam vessel depends mainly upon the variation of immersion which the ship is required to undergo. In river steamers, where there is little variation of immersion, the wheels should be small in diameter. If a line be taken in the length of each float, so that the mean pressure of the water against the float is the same above the line as below it, then this line will constitute a *centre of pressure*, and in determining the velocity of the wheel it is the velocity of the centre of pressure which should be regarded. In all cases the centre of pressure must move more rapidly through the water than the vessel, and the difference between the velocity of the wheel and the velocity of the vessel is termed the *slip* of the wheel. The slip which usually occurs in steam vessels is one-third or one-fourth of the velocity of the wheel; and an imaginary circle described upon the arms of the wheel at that point at which the velocity is the same as that of the ship, is termed the *rolling circle*. The rolling circle should fall above the level of the water. As a general rule, the larger the paddle floats, the more efficient will be the performance of the wheel, as is more fully explained in the article on the SCREW PROPELLER. In radial wheels, the usual practice is to introduce one float for every foot of the wheel's diameter, so that the floats are about three feet apart. In feathering wheels the floats are usually set twice this distance asunder.

Relations of Power and Speed.—With any given type of vessel, and any given power of engine, it is possible to predict, with very considerable accuracy, the speed which a steam vessel will attain. First, a coefficient must be found, which, when introduced into the computation, will give a result answering to that derived from experiment, and this coefficient will vary with the shape of the vessel. In the case of sea-going vessels of good average form, the coefficient is 800; and in the case of very sharp river vessels it is 1,000. Multiply this coefficient by the number of actual horse-power exerted by the engine [HORSE-POWER], and divide the product by the number of square feet in the transverse section of that part of the vessel lying beneath the water. Extract the cube root of the quotient, and this will be the speed which the vessel will attain in statute miles per hour. It is possible to make steam vessels too sharp to attain a minimum resistance, since the increase of length consequent upon increased sharpness involves a larger amount of rubbing surface in the bottom of the vessel, and the loss due to the increased friction may more than counterbalance the benefit accruing from the finer lines.

Circumstances conducive to the Efficiency of Marine Engines.—Supposing the boiler to be properly proportioned, it is necessary to see that the flues or tubes are kept clean, that blowing off be sufficiently practised if the boiler is worked with salt water, and that the furnaces are fed with coal in a regular manner—the coal being distributed evenly over the grate without allowing any holes to exist in the fire. The boilers should be covered with felt to prevent the radiation of the heat, and over the felt sheet lead should be spread, soldered at the corners, so as to prevent any drip of water from the deck having an injurious operation on the boiler. The steam pipes should be covered with felt, and then wrapped round with canvas. The cylinders should also be covered with felt, round which may be placed staves of wood, which should be hooped like a cask. The felt proper for this purpose is thick and soft, and is made expressly for the retention of heat. The steam should be used with a considerable pressure, and be worked expansively; but very little advantage will be derived from working expansively in steam vessels, unless the cylinders be clothed very effectually, so as to prevent the dispersion of the heat. Condensers, which condense the steam without mixing the resulting water with water from the sea, have now come into extended operation; for the only impediment to the use of steam of a considerably higher pressure in steam vessels, is the liability of the boiler to become incrusted with salt, when it might become red hot in some part, and perhaps burst; and this risk the use of fresh water in the boilers would prevent. A species of condenser, called *Hall's condenser*, which operated on the principle of a still, was at one time in pretty extensive use in steam vessels; but it was unskilfully applied in most cases, and the main benefit—the ability to use steam of a higher pressure—was not simultaneously sought to be attained. In Hall's condenser, the steam on escaping from the cylinder passed into a multitude of copper pipes, immerged in a cistern of cold water, and the steam being thus reconverted into water was returned by a pump to the boiler. In another species of condenser, suggested by Symington, a jet of cold water was to be employed, as is the present practice; but the fresh water with which the vessel started, instead of being discharged into the sea, was transmitted through a number of pipes which were kept cool by the sea water, and was returned to the condenser after having suffered sufficient refrigeration. The urgent demand for speed in steam vessels necessitates the employment of a large amount of power, which in its turn involves a large consumption of fuel. To reduce the consumption of fuel, without reducing the power, engines operating more expansively must be employed; but steam of a higher pressure is necessary for the satisfactory operation of such engines, and fresh water in the boilers is conducive to safety where a considerable pressure is employed.

Recent Improvements in the Steam Engine.—Up to the end of 1866 the chief improvements introduced into the steam engine, besides surface condensation in the case of marine

engines, are the use of superheated steam and the substitution of steel for iron in many of the parts. At a temperature answering to a pressure of forty pounds per square inch, salt water deposits sulphate of lime, not from concentration such as that which causes salt to be deposited by a saline solution, but from the mere application of a high degree of heat; and boilers working at a pressure of over forty pounds with sea water cannot be preserved from incrustation by any amount of blowing off. The insides of boilers using surface condensers, however, have been found to be much corroded by the galvanic action of the copper pipes in the condensers unless the pipes are tinned on the side exposed to the sea water; and all marine boilers, when new, should be worked with sea water at first, so as to deposit a thin enamel of scale within them. The steam is usually superheated by carrying it through or among pipes exposed to the heat of the smoke escaping to the chimney, and in practice it is found that if it is heated to a higher temperature than 315° Fahr. it will burn the hemp packings of the stuffing boxes, corrode the valve faces, and hinder the proper lubrication of the piston. Tallow subjected to a high temperature within the cylinder, will sometimes carbonise the piston, and convert it into a substance resembling plumbago. The crank shafts of screw engines are now very frequently formed of steel which is of about twice the strength of common wrought iron. Many screw engines, moreover, have the momentum of the moving parts balanced by counterweights upon the cranks, an improvement introduced by Mr. Bourne in 1853. The counterweights enable engines to work at a high degree of speed without jolting.

For further information on the steam engine, see the *Treatise on the Steam Engine*, by the Artizan Club; *A Catechism of the Steam Engine*, by J. Bourne, C.E.; or *Handbook of the Steam Engine*, by J. Bourne, C.E.

Steam Engine, Agricultural. There are two forms of agricultural steam engine. The first is a vertical or horizontal engine of simple construction, resembling the smaller classes of engines used to drive factories. The second—called a *portable engine*—more nearly resembles a locomotive, and consists of a tubular boiler set upon wheels, to enable it to be drawn from place to place, with a cylinder and its connections usually laid on the top of the boiler and giving motion to the fly-wheel shaft, which is carried across the top of the boiler by suitable brackets. These engines have now been very widely introduced for agricultural and miscellaneous purposes, some of the principal makers turning out nearly 1,000 engines per annum, or something under twenty per week. They are used for driving thrashing machines, for pumping water, for sawing timber, &c. and in some cases also the waste steam is used for steaming food for cattle. They average from eight to ten horses power each. For the most part, agricultural portable engines have a boiler resembling that of a locomotive, but smaller; there being a fire-box and a barrel containing small horizontal tubes for the transmission of the smoke to the chimney. But in a few cases the barrel of the boiler is placed in a vertical position with a cylindrical fire-grate and fire-box; and the fire-box, which is made of great height, has a number of tubes, closed at the lower ends, hanging from its top. These tubes being filled with water, and being acted upon by the flame, generate the steam. To enable a circulation of water to be maintained within these tubes, a thin tube of smaller diameter, and not reaching quite to the bottom, is introduced within each, and the water descends through the internal tube, and ascends through the surrounding annulus. In this case the cylinder is usually attached to the side of the boiler, and is inverted so as to work down to a shaft placed beneath. The wheels of portable engines are generally of iron, and the fore wheels are connected to the boiler by a ball-and-socket joint at the middle of the axle, so as to prevent the engine from at any time resting on three wheels. Usually the engine is drawn from place to place by horses; but in some cases the engine is made to move itself, by imparting motion to the wheels. Further information respecting agricultural engines of modern construction may be obtained in Bourne's *Catechism of the Steam Engine*, 11th edition.

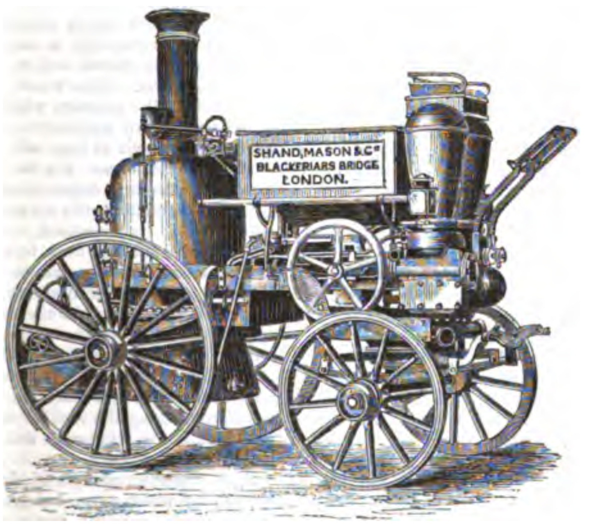
Steam Engine, Substitutes for the. It would be impossible here to recapitulate the expedients which have at different times been propounded for superseding the steam engine. The most promising are electricity or galvanism and hot air. The best forms of the galvanic battery are constructed with zinc surfaces, which are gradually consumed by oxidation. But a pound of coal consumed in a steam engine will produce twice the power generated in an electro-motive engine; and as the cost per pound of the coal is very much less than that of the zinc, it is most unlikely that galvanism will supersede steam, unless a carbon battery can be constructed in which coal will be consumed instead of zinc. The hot-air engine is a contrivance of greater promise; and Ericsson, in America, has constructed many hot-air engines, or, as he calls them, *caloric engines*, which are working successfully in different parts of the world. But as in these engines a cylinder and piston are employed, the temperature of the air cannot be made very high, and unless high temperatures are employed the air engine will not be more economical in fuel than the steam engine, although for some purposes it will be more convenient, inasmuch as the boiler is dispensed with. The most promising expedient of all at the present time is an air engine employing very high temperatures. Such an engine cannot directly employ a cylinder and piston, though it may act on some fluid, through the medium of which the power may be transmitted, or it may consist of a reaction engine, like a Barker's

mill, moving in water. In the case of steam vessels, propulsion may be effected by spouting out steam and smoke below the water at the stern. Various plans have been propounded for propelling in this manner, but none of them have yet been practically successful. That the steam engine will be superseded by a form of air engine using high temperatures, is highly probable; but an electro-motive engine would be preferable, provided that the power could be obtained from coal instead of from zinc.

Steam Fire Engine. An arrangement of pumps worked by steam for extinguishing fires, by projecting upon them a continuous stream of water from a suitable nozzle or spout-pipe.

The first steam fire engine we owe, in common with many other things, to the ingenuity of Ericsson, the eminent Swedish engineer, who subsequently to the completion of his locomotive, the Novelty, in 1830, constructed the first steam fire engine which was used with good effect in the fire which destroyed the Argyll Rooms about that time. In 1832, he constructed, for the king of Prussia, the steam fire engine called the Comet, which had two horizontal cylinders of 12 inches diameter, and 14 inches stroke, and two pumps 10½ inches diameter, and of the same stroke. This engine was set on wheels like those of an ordinary fire engine, and the flow of water was equalised by the aid of a great globular air vessel set behind the driver's seat. This engine weighed 4 tons. It raised its steam in from 13 to 20 minutes, and it threw 336 gallons of water per minute, or about 90 tons per hour.

Notwithstanding the success of Ericsson's early engines, steam fire engines did not come into extended use in this country for more than thirty years afterwards, and then various specimens of such engines came to us from America, which were inferior in constructive excellence to those which Ericsson had long before produced. Latterly, numerous steam fire engines have been constructed by Messrs. Merryweather and Son, Messrs. Shand, Mason, and Co., and by various other makers; and numerous competitive trials have been made to esta-



Steam Fire Engine.

blish the relative efficiency of the engines of the different makers. In the engines of both Messrs. Shand, Mason, and Co., and in those of Messrs. Merryweather and Son, the boilers are vertical; but in the former, the smoke is conducted through a number of vertical tubes to the chimney, whereas, in the latter, the form of boiler known as the *Field* boiler, is adopted, in which a number of tubes filled with water hang from the top of the fire-box, but terminate in close ends above the level of the fire-grate. In these tubes smaller internal tubes are introduced, to enable the water to circulate by descending the internal tube and ascending through the annulus left between the two. In some engines one cylinder is employed, and in others two, but Messrs. Shand, Mason, and Co.'s engines are formed with a crank, whereas Messrs. Merryweather and Son's engines are made without one, and are, therefore, not rotative engines. On the whole, the rotative form of engine appears to be best for pumping as well as for other purposes, as it can be driven faster, and enables the piston to be brought closer to the ends of the cylinder at the termination of the stroke, thereby saving steam. The form of pump commonly used is the bucket and plunger pump, first introduced by Mr. David Thomson, in the Richmond water-works in 1845, and which resembles a common suction pump, with a very thick rod, which acts as a plunger, and the pump consequently forces

both in the ascent and descent of the bucket, but draws only during the ascent of the bucket. In some cases the cylinders and pumps are vertical, and in others horizontal. The figure on p. 591 represents one of Messrs. Shand, Mason, and Co.'s horizontal engines. In an experiment made in 1864 with an engine of this kind with a single cylinder and small fly-wheel, the cylinder being 7 inches diameter and 8 inches stroke, and the pressure of steam 145 lbs. per square inch in the boiler, and 128·16 lbs. in the cylinder, a jet of water 1⅛ inch diameter was projected under a water pressure of 125 lbs. per square inch, the engine making 165 revolutions per minute, with 5½ lbs. per square inch of back pressure resisting the piston. In this case the engine exerted 32¼ indicated horse-power; and as the total weight of the engine was only 32 cwt., the weight was only one cwt. per indicated horse-power. In these engines a small piston, which is pressed against a spring by the water which is being forced out of the jet pipe, governs the speed of the engine by moving suitably the throttle valve in the steam pipe. In April 1866, Messrs. Shand, Mason, and Co. delivered to the Metropolitan Fire Brigade seven of their vertical steam fire engines, those previously in use in that force having been found to act in a most satisfactory manner. They also about the same time sent out three engines to Bombay, one of which was tested in London before being shipped. Steam of 60 lbs. pressure was raised from cold water in 8½ minutes, which threw a jet of water an inch in diameter 150 feet high, and 228 feet horizontal. In the fire brigade stations, it is usual to keep the water in the boilers of the fire engines warm by keeping a small jet of gas alight in the furnace, and by this simple expedient the steam is almost sure to be up before the engine can reach even the nearest fire.

Steam Gauge. An instrument intended to measure the pressure of the steam in the boiler. Steam gauges are of different kinds. One that has been much employed is the *mercurial steam gauge*, which consists of a small U tube of iron which is filled with mercury about half-way up, and the top of one leg communicates with the boiler, while a small wooden float projects above the top of the other leg and points to the graduations on a scale divided into inches, the float pointing to 0 when the steam is not up. If, now, steam be raised in the boiler, the mercury will be depressed in one leg and raised in the other, and every rise of an inch on the scale indicates a pressure equal to that due to two inches of mercury, or very nearly a pound pressure per square inch. Another form of steam gauge is a conical glass tube containing air, against which mercury or some other liquid is forced by the steam; another form, now much used, is that known as *Bourdon's gauge*, which consists substantially of a coiled flat elastic tube, into which steam enters, and the steam causes the tube to assume more nearly the cylindrical form, and simultaneously to uncoil. The amount of uncoiling, as shown by a suitable hand, indicates the amount of pressure.

Steam Gun. A contrivance by which projectiles used in warlike operations may be discharged by the expansive force of steam. This invention is due to Mr. Jacob Perkins.

If a strong close iron vessel, having two valves, one opening inwards and the other outwards—the latter being loaded with some definite pressure—be *completely* filled with water, such a vessel may be heated to the temperature corresponding to the pressure with which the valve is loaded without causing any portion of the water in it to be converted into steam. To render the effect more easily understood, let us suppose that the valve is loaded with a pressure of fifty atmospheres. The temperature of water evaporated under that pressure being 510° [STEAM], the vessel may be raised to any temperature not exceeding 500°, without having any of the water contained in it converted into steam. If the temperature to which the water is raised be 500°, and a cubic inch of water at common temperatures be forced into the vessel through the valve which opens inwards, water being sensibly incompressible, a cubic inch of water at 500° will be forced out at the valve which opens outwards. This water, being no longer subjected to the pressure which kept it in the liquid state, will suddenly expand and flash into steam, which at first will have a pressure of fifty atmospheres, but as it expands will have its pressure diminished in nearly the same proportion as the volume into which it swells shall be increased. Since, however, 500° is not sufficient heat to enable the whole of the water thus ejected to pass into steam [STEAM], that part of it which will assume the vaporous form will take the requisite amount of latent heat from the sensible heat of that portion which remains in the liquid state. As this latter portion will still retain a considerable temperature, it may be conducted to a vessel containing the feed for the heated vessel just mentioned, whence it will be again forced into that vessel.

Such was the principle of Mr. Perkins' *generators*; by which term he denominated those close vessels in which water was raised to a high temperature without being converted into steam.

Now, if the valve through which the heated water is ejected be supposed to be in communication with the barrel of a gun or piece of ordnance, in the same manner as the barrel of an air gun is in communication with the hollow metallic ball in which the air is compressed, a projectile may be discharged by the expansive force of the water ejected from the valve, precisely as the ball of an air gun is projected by the expansive force of the compressed air.

As the water may be ejected from the valve either in a constant stream or by a rapid succession of jets, the projectiles may be discharged from the barrel as rapidly as it is possible for them to be brought under the action of the

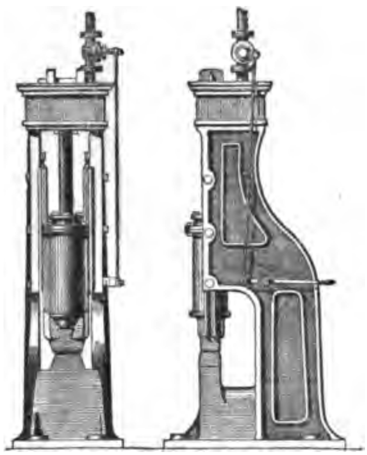
steam; and since the heating of the barrel tends only to increase the elastic force of the steam, there appears to be no other practical limit to the action of such an engine of offence except that which may be imposed on the heating power applied to the generator.

Of the abstract practicability of applying steam in this manner as an offensive engine, there can be no doubt. Both theory and experiment conspire to establish it; but of the comparative efficacy, convenience, and economy of it, compared with gunpowder, many doubts will present themselves to all who duly reflect on the circumstances by which the innovations are surrounded. The necessity of using a steam generator of any kind obviously limits the application of such an instrument to particular cases, and even in those special cases the necessity of employing a generator or boiler which shall reconcile a ready conduction of the heat to the water, with great strength and solidity in the heating vessel, must continue to be regarded as a weighty difficulty. Without a very high pressure of steam the projectile cannot acquire an adequate velocity with any ordinary length of bore; and the use of steam of a very high pressure is dangerous and inconvenient. By greatly increasing the length of the gun, the same effect may be obtained with a smaller pressure; but this expedient is also inadmissible. Hence the steam gun could never come into effect for any but very small calibres; and the places where small guns come into use are precisely those in which it would be most difficult to employ a steam boiler, viz. in the field, in boat service, &c.

Steam Hammer. A heavy hammer, moved by a steam engine, employed chiefly for forging masses of iron and steel, but also for crushing quartz in gold mining, and for other purposes in the arts. Hammers lifted by cams upon a revolving shaft, deriving its motion either from a water wheel or a steam engine, have long been used in certain processes of the iron manufacture. But in the steam hammer there is no intermediate mechanism intervening between the engine and the hammer, and the force and number of the blows are regulated by suitably governing, by a proper valve, the flow of steam to the engine.

The first proposal to apply a steam engine to work a hammer direct was made by Mr. Watt in 1784, but it was not until upwards of half a century later that the problem was practically gone into and solved by Mr. James Nasmyth, then of Patricroft near Manchester. The first steam hammer actually set to work was erected by M. Bourdon in France. But M. Bourdon confessedly obtained his ideas on the subject at Mr. Nasmyth's works, which had been visited by M. Bourdon when he was in England, and to whom the plans of the steam hammer were shown along with the plans of other tools and machines then in progress. But the completion of the steam hammer having been delayed by the progress of other work, and M. Bourdon having begun the construction of such a hammer immediately on his return, it so happened that the French hammer was at work before the English one. In Watt's proposed steam hammer the cylinder was at one end of a wooden beam, while the hammer was at the other, and the hammer, instead of moving vertically as modern steam hammers do, moved in the arc of a circle, being fitted with a wooden shank like the old forge and tilt hammers when moved by cams upon a revolving shaft. But in Nasmyth's arrangement the cylinder is erected over the anvil, and the piston rod which passes through the bottom of the cylinder has the hammer fixed to its lower extremity, the hammer being directed vertically by suitable guides. In Condie's arrangement, the piston is stationary and the cylinder moves, the hammer being attached to the bottom of the cylinder; and the piston rod, which is a stationary cylindrical pipe, serves to convey the steam to and from the

Fig. 1. Fig. 2.



Light Steam Hammer.

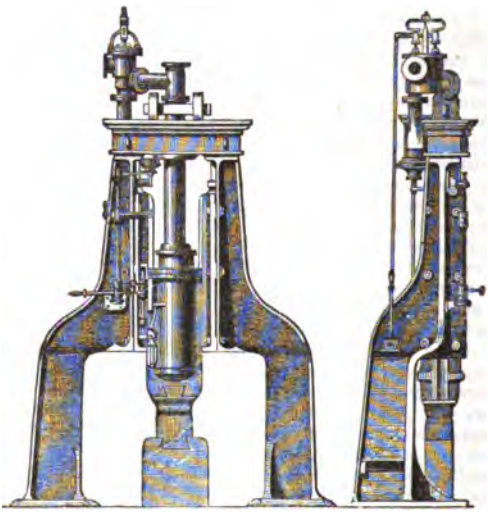
cylinder. Figs. 1 and 2 are a front and side view of Condie's 3½ cwt. hammer, and figs. 3 and 4 a front and side view of Condie's 6 cwt. hammer.

It will be observed that in the lighter hammers the standard is single and the hammer is overhung, while in the heavier hammers the standard is double and the moving cylinder is guided between the two parts. In the early hammers the weight was raised by the pressure of the steam, and the hammer descended by gravity alone; but in all modern hammers the steam presses the hammer down as well as raises it up. Many of the modern hammers are of great size, and of these the standards are generally formed of wrought iron. It is found that hammers of great weight are quite indispensable for consolidating and giving soundness to the Bessemer steel, and it is for this purpose that the very heavy hammers are chiefly employed. In Neilson's radial hammer the cylinder

and hammer are carried on the end of a radial arm, which may be swivelled round a stationary pillar, and the anvil block, which is fitted with various kinds of anvils and dies, is formed like a quadrant struck from the centre of the pillar, to the end that the hammer may by swivelling it be brought down on any particular die. Hammers working horizontally, so as to strike the mass of incandescent metal upon the anvil simultaneously on opposite sides, have also been introduced, and in some cases, too, such a duplex horizontal hammer has been used in conjunction with a hammer working vertically, so that the metal is compressed on four sides at once, the dross and clinker being forced out at the ends.

Steam Hammer for Pile-driving.—An ingenious machine invented by Mr. Nasmyth, now in general use in government and other large works. 'It consists of a steam cylinder, closed at the bottom, but with openings in the top to allow the passage of air; a piston works in it, having its rod passing through a steam-tight aperture in the bottom. To the piston the monkey or driver, which weighs 2½ tons, is attached, and is thus suspended. The machine is worked by high-pressure steam, which being admitted at the bottom of the cylinder by the induction pipe, raises the piston, and, with it, the monkey attached to it. The instant it arrives at the height required, it closes the induction pipe, and, opening the eduction pipe (also at the bottom of the cylinder), the steam escapes, and

Fig. 3. Fig. 4.



Heavy Steam Hammer.

the piston, with the monkey attached to its rod, falls freely on the head of the pile. A large heavy cap of iron, with a hole to allow the head of the pile to pass through, slides between the upright standards, and guides the direction of the pile. The monkey and cylinder also follow the course of the pile, guided by the same uprights, between which they slide.' The entire weight of the steam hammer part of the apparatus, resting all the while on the shoulders of the pile and following down with it, materially assists its penetration into the soil.

The saving of labour effected by this contrivance is very great. A stage, which carries the machine, boiler, workmen, and everything necessary, moves along a railway. Having driven one pile, the machine moves onward the regulated distance; it then picks the next pile out of the water, hoists it high in the air, drops it into its exact place, then covers it with the great cap; the monkey immediately acts, giving blows at the rate of seventy-five in a minute. The whole operation of raising a pile from the raft, putting it in its place, and driving it to the required depth, occupies generally from two to four minutes. By the old method of pile driving, a comparatively light weight (about 12 cwt.) is made to fall from a great height, and the blows succeed at intervals of about five minutes. By the new machine, a very heavy weight (about 50 cwt.) falls through a height of only three feet, and the blows fall 375 times more frequently.

In a paper communicated to the British Association for 1841, Dr. Greene gave the following instance of the state of the heads of two piles, as driven by the two methods:—

'One was fifty-six feet long, driven by a monkey of 12 cwt. falling from a great height, and making only one blow in five minutes, and requiring twenty hours to drive it; this, though protected by a hoop of iron, was so split and shattered on the head, that it would require to be reheaded to drive it any farther. The other, though sixty feet long, was not even supported by an iron hoop, and the head is as

smooth as if it were dressed off with a plane. It was driven with a hammer of 50 cwt. and only three feet fall, making seventy-five blows in a minute, and was put into its place and finished in four and a half minutes.'

Steam Jet. A jet of steam suffered to escape from a pipe, and employed either to accelerate the flow of smoke up a chimney by being projected upwards in the manner in which the waste steam is projected through the blast pipe into the chimney of a locomotive; or it may be employed to cause a current of air for purposes of ventilation, as was done in the Houses of Parliament, where the ventilation was promoted by steam jets. The arrangement is suitable for ventilating steam vessels, by sucking the vitiated air from the cabins. A species of steam jet, called *Delabarre's steam jet*, is sometimes used, of which the peculiarity is, that the jet opens into a short piece of larger pipe, open at both ends, and that into another piece still larger in diameter, and so on; and the air or smoke is sucked in between the successive pieces. Liquids as well as gases may be moved by a jet of steam; and one form of the steam jet, used for forcing water into boilers to feed them, is known as *Giffard's injector*. The action of this instrument appears at first sight paradoxical, as a jet of steam from any given boiler will not only force water into that boiler, but also into a boiler of a still higher pressure. It is essential to the action of the instrument that the feed water shall not be too hot to condense the steam; and the water in the steam must be viewed as water moving with the high velocity with which the steam moves, and which consequently contains sufficient vis viva to force the water in against the pressure within the boiler. Latterly the steam jet has been tried for propelling vessels.

Steam Navigation. The art of propelling vessels by the instrumentality of the steam engine. Vessels so propelled are called *steam vessels*; and the navigation of seas or rivers by steam vessels is termed *steam navigation*. The propelling instrument, by means of which the steam engine acts upon the water, may be the paddle-wheel [Steam Engine] or the screw [Screw Propeller], or any other medium for communicating power; and the vessel is forced forward by the backward pressure of the paddle boards or screw upon the water, just as a boat is forced forward by the reaction of the oars, or as the body of an aquatic bird is propelled by the action of the feet. The pressure with which the vessel is forced forwards is in all cases the same as that with which the water is forced backwards; and this pressure will remain unchanged whether the surface pressing the water be large or small, being dependent altogether upon the power of the engine, other things being equal. But if the propelling surface be large, the water will be moved backwards through only a small distance, while the vessel is moved forward through a great distance, whereas if the propelling surface be small, then with only the same forward motion of the vessel there will be a larger backward motion of the water, and more steam will be expended in producing the same result.

History of Steam Navigation.—Vessels propelled by paddle-wheels driven by oxen were employed by the Carthaginians, and were introduced by them into Sicily, from which country the Romans obtained a knowledge of that method of navigation. In 1543, Blasco Garay, a sea captain in Spain, is reported to have exhibited to Charles V. a vessel propelled by wheels of this kind which were driven by steam; but recent investigations show this story to have been apocryphal. In 1618, and again in 1630, patents were granted in England to David Ramseye for propelling vessels by fire or steam. Various projects for propelling vessels were proposed after this time by Grent, Lin, Ford, Toogood, Chamberlaine, Bushnell, Papin, Duvivian, Savery, Duquet, Dickens, Allan, and Hulls; but so long as the steam engine remained in the cumbrous and ineffective state in which it then existed, no power profitably commensurate with the additional weight could be imparted to a vessel. In 1737, Hulls published a pamphlet describing his mode of propulsion, of which the main features were a paddle-wheel placed at the stern and driven by an atmospheric vacuum engine within the vessel. In 1787, Mr. Patrick Miller, of Dalswinton in Scotland, published a pamphlet describing a new species of vessel which was to be driven by paddle-wheels; but these wheels were to be worked by manual labour by means of capstans. With a vessel constructed by Mr. Miller upon this plan, it was found that a considerable speed was attainable; but the operation of turning the capstan was found to be very laborious, and it occurred to Mr. Taylor, a tutor in Mr. Miller's family, that a steam engine might be applied to perform this work. Mr. Taylor, having shown that such an engine might be introduced without setting the vessel on fire, was commissioned by Mr. Miller to order an engine of an acquaintance of Taylor's, called William Symington, a young engineer of much ingenuity. This engine was made and introduced into a pleasure boat, which was many times tried successfully on the lake of Dalswinton. Mr. Miller then built a vessel on a larger scale, the engine of which was made at Carron. This vessel was tried on the Forth and Clyde canal in 1789, and realised a speed of nearly seven miles an hour. Nothing further was done in the matter, however, till 1801, when Symington received an order from Lord Dundas to construct a steam vessel for the Forth and Clyde Canal Company. Watt's patent having by this time expired, the engine was made upon his plan, and, with Watt's double-action cylinder, the performance of the vessel was satisfactory in every respect. From an impression, however, that the waves which were created would injure the banks of the

canal, this new method of propulsion was not further pursued.

In 1801, shortly after this vessel was completed, she was visited by Robert Fulton, a native of America, at whose desire Symington caused the vessel to be put in operation in order that he might witness her performance. Symington's belief was that the speed of the vessel was impaired by the narrowness of the canal, and Fulton remarked that such an objection could not have existence in the great rivers of North America, where vessels of such a character would confer important advantages. Shortly after this time, Fulton commissioned Boulton and Watt to construct for him an engine which was to be put on board a vessel in America. This vessel was to be propelled by paddle-wheels in the manner previously practised in Scotland. The name of the vessel was the Clermont; she was launched and tried in 1807, and performed her assigned duties in a satisfactory manner. Numerous vessels resembling the Clermont were soon after this time built in America. In 1812, Mr. Henry Bell, of Helensburgh on the Clyde, constructed the Comet, the first steam vessel employed for commercial purposes in Europe. Numerous other vessels resembling the Comet were soon after this built in the Clyde, and steam navigation before long came into general use in all parts of the kingdom. Mr. David Napier, of Glasgow, who had constructed the boiler of the Comet, and who soon signalised himself in this department of engineering, was the first person who sent steam vessels to sea. He established lines of communication between Greenock and Belfast, and, subsequently, between Dublin and Holyhead, and between Dover and Calais. The method of combining two engines with their cranks set at right angles with one another, so as to obviate all danger of the engine stopping at the dead point, and to make the power uniform through the revolution, was a suggestion of Mr. Watt's. When the City of Edinburgh, constructed by Boulton and Watt, was set to run between London and Leith, it was found that the sea water in a voyage of this length acquired, from the continual evaporation of the water without removing the salts, such a degree of concentration that it was no longer fit for the production of steam. The vessel had, therefore, to be stopped in the middle of the voyage, the water let out of the boiler into the hold, and a fresh supply of water to be introduced from the sea. To remedy this inconvenience, Boulton and Watt applied *change pumps* to the vessel, which by continually removing a portion of the super-salted water during the voyage, prevented an injurious concentration from being attained. They afterwards superseded the change pumps by *blow-off cocks*, which on being turned at intervals allowed a portion of the super-salted water to escape overboard. This expedient for preventing an accumulation of salt in the boiler is still generally employed in vessels not employing external condensation, which, however, has now become very general, to enable the boiler to be fed with fresh water, and thus to render the use of steam of a higher pressure practicable with safety, and to obviate the risk of bursting from the accidental accumulation of salt upon the furnaces, when they might become red hot and collapse from the pressure of the steam.

The side lever form of engine, still to some extent employed in steam vessels, was settled by Boulton and Watt at an early period in the history of steam navigation; but the oscillating engine invented by their foreman, Mr. Murdoch, towards the close of the last century, is now generally preferred in the case of vessels propelled by paddle-wheels. It is, however, mainly from the admirable manner in which the details of this species of engine have been carried out by Messrs. Penn and Son, that it has obtained such favourable acceptance and such wide notoriety. Tubular boilers for marine purposes were patented by Mr. Bourne in 1838, but were first practically introduced by Messrs. Penn and Son, and Messrs. Miller and Ravenhill, about 1844.

Ocean Steam Navigation.—Lines of steam navigation now connect together nearly all the countries of the world. Most of the companies carrying on these lines of communication receive large yearly payments from the government for the conveyance of the mails, without which the existing measure of efficiency in the vessels could not be maintained; and it may be taken as an axiom in steam navigation, that no line of distant communication in which a high rate of speed is necessary can be profitable unless supported by a government subvention, or unless some other equitable payment is made for carrying the mails. Some of the vessels carrying on ocean navigation are of 800, 1,000, and even 1,200 nominal horse-power. The actual power of such vessels should be at least six times the nominal. In sea-going steam vessels from 20 to 21 miles an hour is the utmost speed that has yet been attained; but in some cases, the actual power is as great as nine times the nominal. For screw vessels, direct acting engines, or engines without gearing, are now nearly universal. The type most generally and most justly preferred is the double piston rod or steeple engine, laid on its side. [SCREW PROPELLER; TURRET SHIP.]

River Steam Navigation.—The extent of steam navigation upon the rivers of this country is not considerable, the rivers being only in a few cases, or through an inconsiderable part of their length, of sufficient volume to enable navigation to be carried on upon them. Upon the Thames and also upon the Clyde there are many river steamers, well adapted to the functions which they have to perform; but in no case are these vessels of large dimensions or great power. In America, however, where the rivers are of a far larger volume than in this country, and perform a far more important part in the

means of internal communication, there are river steamers of nearly 400 feet in length, and with paddle-wheels 50 feet in diameter, and some of these vessels are said to have attained a speed of 24 miles an hour. The engines are usually set upon the deck, and are formed in the same manner as a common land engine—the beam being poised high in the air and the connecting rod extending from the beam down to the crank. The river steamers of America more nearly resemble arks than ships, as they are built with several decks or stories resting on the hull, which is always made very sharp, so as to enable a high rate of speed to be attained. A pressure of 50 lbs. per square inch is commonly maintained in these engines, if condensing. The stroke of the piston is always very long relatively with its diameter; the steam is of considerable pressure, and is used expansively. The engines are of rude construction compared with English engines, but they are cheap and answer their intended purpose. Upon the Mississippi and its tributaries most of the engines are high-pressure, with the cylinders lying horizontal as in locomotive engines, and accidents by explosion and fire are of frequent occurrence. Some of these engines are worked with steam of 250 lbs. pressure upon the square inch. The muddiness of the water of the Mississippi causes it to froth very much and the boilers to prime, unless steam of a high pressure be employed, which, as it occupies a less volume, occasions less agitation in the water as it rises to the surface. The cabins of American steamers are in nearly all cases very handsome and spacious; the boilers are usually disposed at the sides of the vessel behind the paddle-boxes, so that the ashes fall into the river; and the steering wheel is placed on the upper deck near the bow, and communicates with the rudder at the stern by means of iron rods or chains.

Steam Navigation upon shallow Rivers.—The shallowness of many of the rivers of the continent, on which it became important to establish steam navigation, has led to the introduction of very light vessels upon them. Upon the upper part of the Rhine, and upon the Moselle, there are vessels plying which draw only 11 inches of water. Upon the Loire there are vessels plying which draw only from 8 to 10 inches of water, and upon the Red River, a tributary of the Mississippi in America, there are vessels plying which are said to draw only 7 inches of water. These vessels of course do not carry cargo, but only passengers. Mr. Bourne introduced a species of steam train for navigating the rivers of India, and especially the Indus, consisting of a steamer of light draught towing a train of shallow barges laden with cargo; and it is reckoned that by this simple expedient ten thousand miles of river, now inaccessible, would be laid open to commercial intercourse by steam.

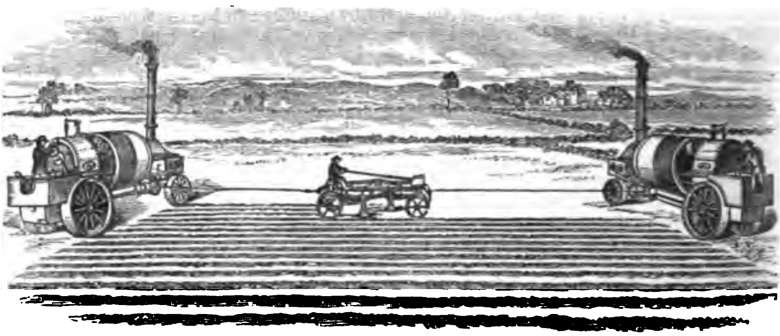
Steam Navigation upon rapid Rivers.—A method of towing barges by steam has for some years past been in successful operation upon the Rhone, which appears likely to be of service in all cases where rapid rivers have to be ascended with heavy loads. Upon the paddle shaft a toothed drum is fixed which engages an endless chain. This chain passes round a great wheel like the fly-wheel of an engine, but armed with projecting spikes, which is placed at the lower extremity of a wooden frame hinged at its upper end, so that it can rise and fall with the irregularities of the river bed, and this wheel, being put into revolution with about one-third of the speed of the paddles, hauls the vessel up against the stream by means of the chain. The paddles are thrown out of action when this wheel is in operation, but are used in descending the river, when the great wheel, which rises through a well in the centre of the vessel, is hoisted out of the water.

Steam Ploughing. The art of cultivating land by the steam engine has now been practically matured; but as the requisite machinery would be too expensive for most farmers to purchase, and too powerful for them to require constantly, companies have been formed in different localities to let out steam machinery for ploughing and thrashing on hire. Various expedients for ploughing by steam have been tried, one of which was a species of digging machine in which a wheel armed with spades or diggers was rotated by an engine, and which simultaneously turned up the ground and drew forward the machine. By another method, a traction engine, made either with an endless railway like Boydell's, or very broad wheels and projecting grippers like Bray's, advanced over the ground, drawing a number of ploughshares behind it. But the method of ploughing now generally adopted consists in drawing a frame on wheels, and armed with a sufficient number of ploughs, backward and forward over the field by means of a rope of steel wire wound up by a portable agricultural steam engine. There are two systems of rope tillage, in one of which a single engine is used, and in the other two engines. In the first system, the engine is placed at one end of the field, a pulley, armed with a suitable anchor for fixing it to the ground, being placed at the other end. A wire rope, proceeding from the engine along the length of the field, passes through the pulley and returns again to the engine. This rope is then drawn backward and forward across the field, carrying the frame of ploughs with it, which frame is so poised on central wheels that when the set of cutters in front of the wheels is in the earth the other is out, and vice versâ, to the end that the ploughs may act equally in whatever direction the rope is pulled. In the other system—which appears to be preferable—two engines are used, one being placed at each end of the field with a rope extending between them, and the same species of plough is attached to the rope and is drawn alternately backward and forward by the engines alternately winding and unwinding—the engines being of course advanced through a

suitable distance along the ends of the field at each cut that is taken. This arrangement is shown in the annexed figure, which represents Savory's apparatus for steam ploughing. But there are various other forms of apparatus, such as Fowler's, Howard's, Smith's, &c. Steam ploughing companies generally charge farmers 12*s*. per acre for ploughing their land 12 inches deep, 10*s*. for 9 inches, and 8*s*. for 7 inches. The farmers, by the aid of such companies, get their stubbles and seeds broken up and crushed at two operations for 18*s*. per acre, and their ploughing and digging performed at from 10*s*. to 18*s*. For ploughing with short breasts for turnips or barley before sowing they are charged 12*s*. 6*d*. per acre. Fowler's tackle gets through $1\frac{1}{4}$ acre per hour, and works without trouble or breakage. Howard's machinery is also well spoken of, and works through stony and uneven ground without injury. The engines come to the ground with the steam up, and when two engines are employed there is no time lost in fixing tackle, which on the single-engine system occasions much delay.

Steam Press. [PRINTING MACHINE.]

Steam Riveting Machine. A machine for riveting, by the pressure or percussion generated by a steam engine, the plates of metal which enter into the composition of boilers and other similar structures. Formerly, the plates of metal having been punched by a punching press, red-hot rivets were inserted, which were clinched over by hand hammers, and this mode of procedure is yet practised in situations where the riveting machine cannot be applied. But work riveted by machine is not only cheaper than that riveted by hand, but is sounder and better, while the machine forces the plates so closely together that very little caulking suffices to make the joints tight.



Steam Ploughing.

There are two kinds of riveting machines. In the one the die for forming the rivet is pressed against the plate in the same manner as the punch is pressed in a common punching machine; in the other, it is pressed forward by a piston urged by steam in the same way as a steam hammer. The first of these varieties is the form of riveting machine first contrived by Mr. Bourne in 1834, and subsequently adopted by Mr. Fairbairn. The second variety, which is the offspring of the steam hammer, was not contrived until the Menai tube came to be constructed. The steam hammer form of riveting machine is the most convenient, as it does not require any adjustment for the thickness of the plate, and it is the form now generally preferred.

Steam Room. The space in a boiler appropriated to the storage of the steam, and which includes the whole content of the boiler except that occupied by the water and flues.

Steam-made Ice. One of the most remarkable applications of the steam engine is to the manufacture of ice, which is accomplished by forcing the heat out of air by mechanical compression, and then by allowing the compressed air to expand, whereby such a demand is made for the restoration of the heat before forced out as to produce a great reduction in the temperature of surrounding objects. Mr. Bourne states that in his first visit to India, in 1847, the inconveniences caused by the heat led him to contrive a machine in which cold would be produced by the expansion of air previously compressed by a steam engine, the expanding air being at the same time used to work the punkahs or great fans which are suspended from the ceilings of the rooms to produce an agitation of the air. In the first ice-making machine constructed on this principle in America, the vapour of ether was employed instead of air, a pump being introduced to create a vacuum, when the ether evaporated rapidly, producing great cold, and this vapour being then pumped into a vessel under pressure it assumed the liquid form, when it was again available to be evaporated as before. Brine was made to circulate through pipes traversing the refrigerated ether, and these pipes being continued through cisterns of water, the water was so much cooled by the contact of the cold pipes that it froze and was taken out in blocks. This machine was introduced into India and some other tropical countries. But it was found that the ice made by it was opaque instead of being transparent like ordinary

ice, a peculiarity imputed to the circumstance of the freezing having been begun from beneath the water instead of from the surface. It was also found that the use of ether was objectionable and dangerous, and in the Bathgate paraffine oil works, where one of these machines was employed to separate the paraffine by refrigeration, it was judged expedient to discard the ether and to revert to the use of air as the refrigerating agent, which accordingly was done under the direction of Mr. Kirk, the engineer of the works. The first experiments were not successful owing to conduction, the presence of moisture in the air, and the absence of a regenerator; but by using dry air and introducing a regenerator of wire gauze, like that of Stirling's air engine, a very efficient refrigerating apparatus was obtained. A still larger machine was erected by Mr. Kirk at the same works in 1864, and an account of it will be found in *Engineering* for January 26, 1866. This machine has two cooling cylinders of 36 inches diameter and 2¾ inches stroke, and one compressing cylinder of 15 inches diameter and 30 inches stroke. Pressure of air in one cylinder, 100 lbs. per square inch maximum and 52 minimum; revolutions per minute, 66; indicated horse-power spent in driving, 23; quantity of cooling water per minute, 4·3 gallons; temperature of inflow, 62°—of outflow, 94°; quantity of brine cooled per minute, 6·7 gallons; temperature of inflow, 32°—of outflow, 23°. Professor Rankine calculates that there are 767 units of heat generated per minute in this machine, which are equivalent to 592,124 foot pounds per minute or 18 horse-power. But the power really consumed, as shown by the indicator, is 23 horses, leaving 5 horses not accounted for, and lost by leakage of heat or otherwise. In many of the arts the power of cooling to any desired temperature is most important, and in tropical climates refrigeration by steam, or other cheap available power, may be easily effected and will be productive of the most momentous benefits, especially in hospitals, barracks, offices, churches, and in all large places of assembly.

Steamer. A term vaguely used for any vessel in which the propulsion is by steam, otherwise than as an auxiliary motive power.

Stearates (Gr. στέαρ, *fat*). Stearic acid forms both neutral and acid salts. The stearates of the alkalies are soluble in water, alcohol, and ether; but when the aqueous solutions of the neutral compounds are largely diluted, they deposit flakes of the acid stearate. The stearates of the alkaline earths may be obtained by double decomposition, from bistearate of potash: they are insoluble. Stearate of potash is the basis of *soft soap*, and stearate of soda of the principal *hard soaps*: these stearates are separated from their solutions in water by excess of alkali, and also by chloride of sodium and some other salts. Stearate of lead is the basis of lead-plaster.

Stearic Acid ($HO, C_{36} H_{35} O_3$). When stearin is saponified, it is resolved into stearic acid and glycerine, a change which has been represented by the following equation:—

$$\underbrace{C_{114}H_{110}O_{12}}_{\text{Stearin.}} + 6HO = \underbrace{C_6H_8O_6}_{\text{Glycerine.}} + \underbrace{3[HO, C_{36}H_{35}O_3]}_{\text{Stearic acid.}}$$

The acid may be obtained by decomposing a soluble stearin soap by tartaric acid, and purifying the product by solution in boiling alcohol, from which it separates in crystalline flakes; it may be further purified by solution in ether. It is white, inodorous, and tasteless, but it reddens litmus: it fuses at about 160°, and may be distilled in vacuo, but when highly heated in the air it undergoes more or less change. Stearic acid may be distinguished from stearin by its ready solubility in a boiling solution of potash.

Stearin (Gr. στέαρ). That part of oils and fats which is solid at common temperatures. It is a compound of stearic acid and glycerine, and is resolved into those proximate components in the process of saponification. It fuses at about 140°. The formula assigned to stearin is $C_{114}H_{110}O_{12}$. Its resolution into glycerine and stearic acid in the process of saponification has been represented by the following equation:—

$$\underbrace{C_{114}H_{110}O_{12}}_{\text{Stearin.}} + \underbrace{6HO}_{\text{Water.}} = \underbrace{C_6H_8O_6}_{\text{Glycerine.}} + \underbrace{3[HO, C_{36}H_{35}O_3]}_{\text{Stearic acid.}}$$

Steatite (Gr. στέαρ, στέατος, *fat*). A massive variety of Talc, with a smooth greasy feel, like that of suet, and so soft as to yield to the nail. It is a hydrated silicate of magnesia, and is found near the Lizard Point in Cornwall, at Glyder Rock and Moel Siabod in Carnarvonshire, Portsoy in Banffshire, Canada, &c.

Steatite is a material much used in China for carving into grotesque figures [Agalmatolite]; and slabs of the same stone are, from their refractory nature, employed for lining ovens and furnaces. It is also made into gas-burners, which possess the advantage of not corroding or becoming stopped up. [Soapstone.]

Steatoma (Gr. στέαρ). A tumour, the contents of which are of the appearance and consistency of hard fat.

Steel (Ger. stahl, Dutch staal). This most useful and curious substance is a compound of iron and carbon. The relative proportions vary in steel of different qualities; but in that used for ordinary purposes the carbon rarely exceeds 2 per cent., and is generally about 1·5 per cent. Certain kinds of iron are preferred to others in this manufacture; but this relates entirely to its purity, which is the essential requisite. Steel is sometimes made by a process called *cementation*, which consists in filling a proper furnace with alternate strata of bars of the purest malleable iron and powdered charcoal, atmospheric air being carefully excluded from the boxes containing the bars, and the whole kept for several days at a red heat. By this process carbon penetrates, and combines in the above small relative proportion with the iron, the texture of which, originally fibrous, becomes *granular*, and its surface acquires a *blistered* character. Much of the steel now used is,

however, made directly from cast iron, by removing a portion of the carbon which the latter contains. This is effected by exposing the molten iron to a current of air, either on the sole of a REVERBERATORY FURNACE or in large egg-shaped iron vessels lined with fire-clay. The latter process is known as Bessemer's, and yields an excellent product. Steel made in the reverberatory furnace is commonly termed *puddled steel*. The malleability of steel falls far short of that of iron; but it is harder, more sonorous and elastic, and susceptible of a higher polish, while it has less tendency to rust. At a red heat it may be hammered into various forms, or welded by the blows of the hammer to another piece of steel or iron. Blistered steel, rolled or beaten down into bars, forms SHEAR STEEL; and if melted, cast into ingots, and again rolled out into bars, it forms *cast steel*, which when well prepared has the great recommendation of perfect uniformity of texture, and a finer and closer grain. The peculiarity of steel, upon which its high value in the arts in great measure depends, is its property of becoming, if suddenly quenched in water, when at a bright red heat, extremely *hard*, and of being again *softened* down to any requisite degree by the application of a certain temperature, which may be indicated by a thermometer, commencing at about 300°, and terminating at a dull red heat. This process is often called *tempering*; and the workman is sometimes guided in the extent to which it is carried by the *colour* of the polished surface of the heated steel, which is at first rendered of a pale straw tint, then yellow, brownish purple, and blue, as the temperature rises from one extreme to the other. The latter colour indicates extreme softness and elasticity, such as belongs to watch springs, some sword blades, &c.; pale straw indicates great hardness, as for razor blades; yellow is somewhat softer, and shows a fit temper for penknives; and the incipient blues announce the temper that belongs to coarser cutting instruments, and to table knives, any of which, made of hard steel, would soon get spoiled and notched, but the edges of which, when duly tempered, resist breaking on the one hand, and bending on the other. When a large mass of steel is hardened by quenching in water, it undergoes a certain degree of expansion, so that the specific gravity of hard steel is somewhat less than that of soft. Attempts have been made to improve the quality of steel for certain purposes by adding to it small portions of other metals: hence the term *silver steel*, &c.; but none of these alloys have, on the whole, proved superior to well-made common steel. There is a kind of steel imported from India, known under the name of *wootz*, the cutting instruments of which are celebrated for the toughness and durability of their edge. It appears probable that its peculiarities depend upon the presence of a little aluminum. When the surface of some kinds of steel is washed over with a weak acid, it acquires a peculiar mottled or *damasked* appearance, as if its texture consisted of an intimate mixture of two different kinds of steel, or of fine fibres of steel and iron. Steel, alloyed with a little nickel, often puts on this appearance; but these and some other imitations of the celebrated *Damascus* sword blades have not led to any important improvements in the manufacture of our cutting instruments.

Steel Engraving. The art of engraving on steel. [ENGRAVING.]

Steel Guns. Since the introduction of rifled ordnance into the armaments of Europe and America, great endeavours have been made to obtain a material capable of withstanding the great strain to which rifled guns are subjected, and especial attention has been directed to steel.

In this country, guns entirely made of steel have not been adopted, but many of the service built-up guns have their inner barrels of steel. These barrels are not cast in the government works, but are obtained from private manufacturing firms in the form of cylindrical blocks, which are afterwards tempered, bored, and turned in the Royal Arsenal at Woolwich.

The process of manufacture of these blocks is as follows: Bars of blistered steel, made by the ordinary cementation process from wrought iron, which has been obtained by puddling without refining, are broken up into lengths of about five inches, and arranged according to quality. From them a mild steel is selected, containing but little carbon, and with small crystals. The pieces selected are placed with a little flux (oxide of manganese) in crucibles having tightly fitting covers, and are melted in air furnaces, heated with coke, below the floor of the foundry. Each crucible contains about 45 lbs., and is heated before being charged. A little glass, thrown in before the steel melts, forms an air-tight crust on the top of the metal, which latter takes about three hours to melt.

As soon as the metal is melted, the pots are lifted out, and run upon wheels to the mould, which is composed of cast iron coated with oil and black lead. The covers being removed and the crust broken, the metal is poured into the centre of the mould, a casting of six tons taking about 280 pots, and occupying about ten minutes in casting. The ingot is then allowed to cool gradually, and, when cold, the lower end, which is most dense, is marked for the breech, and about one-third of the ingot is cut off from the upper end. The ingot is now drawn out under a heavy steam hammer to the proper length, as much as possible by pressure, and not by sharp blows, which injure the metal, on which account hydraulic presses are coming into use for this purpose instead of hammers. This drawing out is performed at a moderate heat, which is acquired generally in a Siemen's regenerating furnace. When complete, the block is lacquered, and the ends are faced.

The block in this condition is sent to the Royal Arsenal, and there tested, when, if

accepted, it is tempered in the following manner: It is placed in an iron cylinder, and surrounded by a wood fire till brought to a dull red heat, when it is lifted out and dropped into another cylinder containing cold oil, where it remains till cold, the oil being kept cool by the constant flowing of a stream of water round the cylinder in which the oil is contained. By this process of tempering, the hardness and tenacity of the metal are increased, and its ductility and specific gravity decreased, probably by the free carbon becoming chemically combined, and the crystals of steel being thus fixed in their expanded state. The block is then bored and turned.

Although in our service these steel blocks form only the inner barrel of the gun, and are strengthened by shrinking on over them a series of wrought-iron coils in a state of initial tension, as explained in the article RIFLED GUNS, in many other countries solid steel guns are employed. The chief maker of these is Herr Krupp, of Essen, in Prussia, whose cast steel has attained such eminence, and has of late excited so much curiosity, that a sketch of the chief peculiarities of its manufacture, abridged from the *Report of a Professional Tour of Officers of the Royal Artillery in* 1865, may not be out of place here. Krupp's cast-steel guns have been adopted not only by Prussia, but to a considerable extent by Russia, Belgium, some of the minor German states, Austria, Holland, Italy, Egypt, Turkey, and even Japan. At the close of 1865, he had made upwards of 2,500 guns, 400 of which were of 8-inch calibre and upwards.

The ore employed in these works is partly obtained from Krupp's own mines at Nassau and Coblentz, and partly bought, the former being spathic, furnishing the well-known *spiegel-eisen*, the latter being red iron-ore, both smelted with coke. The greater proportion of the cast iron is brought into the form of puddled steel, but some is carried through to wrought iron, and a small quantity of cemented steel is bought. A modification of Bessemer's process is employed to convert some of the metal into wrought iron.

The metal of which guns are composed is a mixture of steel and wrought iron, melted in plumbago crucibles holding about 30 lbs. each, so small a quantity only being used, as this soft metal is difficult to melt and manage. The pots rest on loose bars in furnaces, and can only be used once, as the heat attained brings them to a state of incipient fusion. In the centre of the foundry is a pit containing the mould, and the reservoir, whose office is to secure a steady vertical flow of the metal into the mould. Troughs lead to the reservoir.

When the crucibles are taken out, the covers are not removed, but the metal is poured out through a hole in the upper edge into the nearest trough. Great care is taken, and wonderful perfection has been attained, in timing the movements, so as to keep the molten metal flowing in a continuous stream into the reservoir. As many as 400 men are employed in a cast of 16 tons. The cast is allowed to cool till it has shrunk sufficiently from the mould to be turned out, when it is surrounded by hot cinders, and kept hot (cherry red) till wanted for forging, sometimes for as long a period as three months.

For the sake of homogeneity, all castings are made cylindrical or square, and hammered to the rough shape required, which increases the density, strength, and elasticity. This hammering is continuous, the ingot being kept at the same temperature by frequent heats. When fully worked, the breaking strain of the metal used for guns is about 44 tons per square inch.

The smaller kinds of guns are fashioned from one solid piece; those above 8-inch calibre are compound, being weighted and strengthened by external rings. Th 11-inch gun, for instance, is cast as a solid cylinder weighing 35 tons, and of seven feet diameter, and is afterwards hammered out, and shaped, being turned down to a thickness over the charge of one calibre. The trunnion ring, which is also a cast-steel cylinder forged into shape, is shrunk on, and the breech strengthened by the addition of hoops of cast steel forged as above to a breadth of ten and a thickness of six inches. These guns are 16 calibres in length, and weigh 28 tons. A 15-inch gun is being made for the Russian government.

The largest hammer used in forging is one of 50 tons, with a fall of 10 feet. It is intended to erect one of 120 tons, with a drop of 13 feet, the estimated cost of which is 200,000*l.*

The only experiments made with Krupp's guns of large calibre have been carried on in Russia, and the results are embodied in a report presented to the emperor by a commission, including among its members General Todleben and other distinguished men. A 9·65-inch rifled muzzle-loading gun, weighing 148 cwt., with projectiles of 269 lbs. and a charge of 45 lbs. of prismatic powder (weaker than English common powder), burst at the 66th round. This was attributed to the wedging of the shot in the bore. An 8·58-inch gun, with charges of 33 lbs. and shot of 220 lbs., burst at the 109th round. It was rather heavier than the 9·65-inch gun. Four guns, all muzzle loaders, three of 8½ inches, and one of 11 inches, were then tested for endurance. Two of them, which were rifled, withstood, the one 215 rounds, the other 286 rounds, 46 rounds with each being fired with 33 lbs., the remainder with 27½ lbs. of powder. The other two were smooth bored, and withstood 1,025 and 790 rounds respectively with round shot and charges of prismatic powder about ⅙ and ¼ the weight of the shot. None of these four guns were fractured, but were all worn or eaten into at the seat of the shot by the gas, to such an extent that the committee considered that the service of these guns cannot with safety be assigned a higher duration than 250 rounds. The two guns which were fractured are reported to

have been of exceptionally good metal, uniform, homogeneous, and of great tenacity; but they evidently burst from overwork, the charges being excessive.

Such are some of the principal results as yet attained in the manufacture of steel ordnance. In comparing this metal with others, as a material for guns, there are several points to be considered. Putting aside cast iron as uncertain in tenacity and wanting in elasticity, and bronze as wanting in hardness and elasticity, and therefore unfitted for rifled guns to be fired with large charges, it may be desirable to glance at the comparative merits and defects of steel and wrought iron. The same drawback that exists to the employment of large forgings of wrought iron, viz. the impossibility of obtaining perfectly sound masses of metal, must evidently apply to any steel but cast steel; steel, however, can be melted at a practicable heat, and run into large masses, and so, if the casting be carefully carried out, homogeneity and soundness may be obtained. It also possesses the important advantages of greater elasticity, tenacity, and hardness.

Steel, however, though possessing a greater tenacity or ultimate cohesion than wrought iron, and a greater elastic limit within which no change of form will take place, does not possess between its elastic limit and its ultimate cohesion the same ductility or extensibility as wrought iron; so that, while the latter will stretch after its elastic limit is passed or overcome by sudden strain, steel will break and fly into destructive pieces—a fatal fault in a gun.

If it were possible to obtain a steel which with its great elasticity and tenacity would combine great ductility, the best cannon metal would be found. Some of the low steels or homogeneous iron, which by Kirkaldy's experiments were shown to have a considerable extensibility before fracture, seem to approach near to these qualifications. But, unfortunately, as the one valuable property increases, the other diminishes. *Low steel*, or, as it is called, *mild steel*, *soft steel*, or *homogeneous metal*, containing but little carbon, possesses greater elasticity and tenacity than wrought iron, with some extensibility; but *high steel*, containing more carbon, though more tenacious, hard, and elastic, is wanting in ductility to such an extent as to make it altogether too brittle for guns.

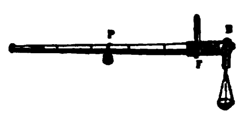
Unless, then, the manufacture of steel be improved, it seems that, if steel guns be used, such an excess of metal must be given to them as will add greatly to their power of resistance, and will render them capable of resisting high charges. But there is a limit, at which no addition of thickness to the exterior of a gun adds anything to its resisting power, and this is reached when the maximum pressure per square inch exerted on the interior equals the resistance of the metal at the point of rupture; for at this point the internal laminæ will tear asunder, and so outwards in succession, on further strain. Now, the thickness at which internal rupture will commence is inversely as the final extensibility; and the coefficient of extension of steel is so small that the thickness at which any further addition will be useless is soon reached. It remains only, then, to fire with small charges, such as will avoid all risk of overcoming the elastic limit of the metal.

Here we meet with this obstacle, that we have not yet succeeded in measuring in any way at all satisfactory the initial strains of various charges of powder fired under various conditions. Could this be done, we might accurately apportion the charge to the strength of the metal, which is capable of being ascertained. Till then we work in the dark, using empirical rules.

The other chief point to be taken into consideration is the great cost of steel, caused in the first instance by the expense of melting and casting, the careful selection of the material, &c. If the Bessemer process, which is based upon true principles, can be carried to greater perfection, this may be overcome in time; but the cost of turning and boring such a hard metal will always be very great.

How far steel tubes strengthened by external rings in a state of tension will stand, is still a question open to argument. Steel tubes are at present employed by the government authorities at Woolwich for the large muzzle-loading guns; but some guns will be constructed with barrels of Marshall's wrought iron, which is of most excellent quality. The steel tubes have shown a tendency to split; but if the charges have been excessive, this is only what must follow from the principles above explained.

Steel Yard. A balance by which the weights of bodies are determined by means of a single standard weight. The instrument, which is represented in the annexed figure, is a lever having unequal arms. The load, the weight of which is to be determined, is suspended from the extremity B of the short arm; and in weighing, the constant weight or counterpoise P is slid along the longer arm until the equilibrium is established. Divisions traced on this arm indicate the weight at B corresponding to each position of P.



In the Roman steel yard, or *statera*, the lever was so constructed that the centre of gravity was brought immediately over the point of support; and the system being accordingly balanced upon its fulcrum F, the effect of the weight of the lever was neutralised. The longer arm was then divided into parts, each equal to the shorter arm, and those again equally subdivided. Suppose now the length of the shorter arm, or the distance F B, to be one inch, and the constant weight P to be one pound; then if P be placed at the distance of five inches from F, it will make equilibrium with a load of five pounds suspended from B; for, from the

property of the lever, when the equilibrium is established, the weight P is to the load at B as the distance of B from F is to the distance of P from F. Whatever proportion, therefore, FP has to FB, the same proportion has the weight suspended from B to the constant weight P.

The steel yard in common use is constructed somewhat differently, the beam being seldom made so as to balance itself on the fulcrum F; but the error arising on this account is compensated by beginning the divisions at that point where the equilibrium is established, when the weight P is placed upon it. If, therefore, when P is removed, the longer arm preponderates, the divisions commence from a point between F and B. For the purpose of increasing the range, there are also in general two fulcra, from either of which the beam may be suspended, and two corresponding scales of division are marked on opposite sides of the longer arm.

For weighing heavy loads the steel yard is a convenient instrument; but for smaller weights it is susceptible of less accuracy than the common balance. It should be constructed so that the point of support F, and the point of suspension at B, may be in the same straight line with the divisions of the beam.

Steel Yard, Merchants of the. A company of London merchants to whom the STEEL YARD was assigned by Henry III. A.D. 1232. They were all foreigners, chiefly Flemish and German, and were long the only exporters of the staple commodities of England.

Steening or **Steining.** In Architecture, the brick or stone wall or lining of a well.

Steeple. In Architecture, a tower of various forms, usually attached to churches and other public buildings, in which bells are frequently, but not always, suspended.

Steer (Ger. steuern). To keep a ship on a given direction. This is done by moving the rudder by the tiller, which last is moved to the opposite side to that towards which the ship's head is required to proceed.

Steerage. The steering of the ship. Also a place below in the fore part of ships, as distinguished from the *chief cabin*; but the term is of uncertain acceptation.

Steganography (Gr. στεγανός, *covered*, and γράφω, *I write*). The art of writing in CYPHER.

Steganopods (Gr. στεγανόποδες, *web-footed*). The name of a family of swimming birds (*Natatores*) in the system of Illiger, including those species in which all the four toes are connected by the same web. It corresponds with the genus *Pelecanus* of Linnæus.

Steinerian of a Plane Curve. The locus of the intersections of the pairs of lines which constitute the polar conics of the curve; in other words, the locus of double points on all polar conics, or, what is the same thing, the locus of the *poles* of all first polars which possess double points. [POLES AND POLARS.] The locus of these double points on first polars is the Hessian, since by the law of reciprocity the polar conic of every such double point breaks up into two right lines. The Hessian and the Steinerian, therefore, are closely related; the polar conic of a point on the Hessian has a double point on the Steinerian, and the first polar of a point on the Steinerian has a double point on the Hessian. They were called conjugate *kerncurven* by Steiner (Crelle's *Journal*, vol. xlvii. 1854); the name Hessian was proposed by Sylvester (*Phil. Trans.* 1853), and that of Steinerian by Cremona (*Memorie dell' Istituto di Bologna*, t. xii. 1862). The Hessian is of the order $3(n-2)$, the Steinerian of the order $3(n-2)^2$. The Hessian passes through all the points of inflexion on the primitive curve, whilst the Steinerian touches all its stationary tangents. For cubics both curves coincide; a point on the Steinerian, and the double point on its first polar, then become *corresponding points* on the Hessian. [CUBICS.]

Steinheilite. A variety of Iolite, found with Copper Pyrites, at Orijerfvi in Finland. It is of a blue colour, and is considered by jewellers an inferior variety of Sapphire. Named after Count Steinheil.

Steinmannite. An impure variety of Galena. It is a double sulphide of lead and antimony, occurring in octahedrons, also massive, and in botryoidal and reniform aggregations of a lead-grey colour, at Przibram in Bohemia. Named after the chemist Steinmann.

Stela (Gr. στήλη, *a post*). In Architecture, a small column without base or capital, usually with an inscription to record an event, or to perpetuate the memory of some deceased person. Stelæ were also used for marking distances, and several specimens may be seen in the British Museum.

Stellatæ (Lat. *set with stars*). In Botany, a natural order of Exogens, also known under the name of GALIACEÆ.

Stelleria. A generic name given to an extinct northern *Manatee*, from its discoverer the Russian traveller and naturalist Steller: it is now more commonly called *Rhytina borealis*.

Stelleridans (Lat. stella, *a star*). Star fishes. The name of the family of Echinoderms of which the genus *Asterius* is the type.

Stellio (Lat.). The generic name given by Cuvier to those Iguanian lizards that have the tail girt by rings composed of large and sometimes spiny scales.

Stellionate (Lat. stellionatus). In the Roman Law, a general term comprehending all sorts of fraud committed in matters of agreement which were not designated by any more special appellation. The name is said to be derived from stellio, *a lizard*, because the fraudulent man may be compared with that animal for versatility and address. The six common species of stellionate enumerated by Roman writers were: 1. When one sells the same thing to two purchasers; 2. When a debtor pledges to his creditors something which does not belong to him; 3. When one abstracts or damnifies

something which he has pledged to creditors; 4. Collusion by two parties to the prejudice of a third; 5. When a vendor substitutes an object of less value for that which he has engaged to sell; 6. A wilful false declaration in an instrument.

Stellite (Lat. stella, *a star*). A white translucent variety of Scolezite, crystallised in concentric stellar groups of delicate rhombic prisms, at Kilsyth, Scotland, embedded in greenstone.

Stem (Ger. stamm). The ascending axis of a plant: that part of a plant which bears or has borne leaves or their rudiments; the upward axis of growth. It is sometimes subterranean, but more commonly exposed to the air and light.

Stem. In Music, the upright or downright line added to the head of a musical note; the head being that part filled in black or left open, as the case may be.

Stem. A strong timber, forming in a ship the wedge-like front. It is united by a scarf to the keel and rises nearly perpendicularly from it. The fore-ends of the planks of the side are firmly embedded in the stem. It is backed by the *apron* and *stemson*.

Stemless. In Botany, this term denotes the absence of a visible or obvious stem.

Stemples. In Mining, cross bars of wood in the shafts of a mine.

Stemson. [Stantion.]

Stencil. A piece of thin leather or oilcloth, used in painting on walls. The pattern, cut out of such pieces, is laid flat on the wall, and the colour is brushed over it.

Stenelytrans (Gr. στενός, *narrow*; ἔλυτρον, *a sheath*). The name given by Latreille to a family of Coleopterous insects, comprehending those in which the elytra become narrow at the posterior part of the body.

Stenography (Gr. στενός, and γράφω, *I write*). The art of short-hand, otherwise termed *tachygraphy*. This art has been practised from remote antiquity, and it is said to have originated in the hieroglyphics of the Egyptians.

Stentor. In the *Iliad*, a herald of the Achæans, whose voice was as loud as that of fifty men: hence the adjective *Stentorian*.

Step. A block of wood, or in large ships a strong solid platform, upon the keelson, supporting the heel of the mast, and spreading the pressure. It was found that the weight of the mast, yards, &c. added to the enormous force upon the rigging, especially during strong winds, forced the keel down.

Stephanite or **Black Silver-ore.** Native sulphide of silver and antimony, composed (when pure) of 70 per cent. of silver, 14 antimony, and 16 sulphur. It is a valuable ore of silver, of a dark lead-grey or iron-black colour, with shining metallic lustre, and is found associated with other silver-ores principally in Saxony, Hungary, Bohemia, and the Harz. Named after the Austrian archduke Stephen.

Steppes (Russ.). The name given to part of the low tracts of flat land in the northern parts of the Old World, traceable from the shores of the German Ocean through Holland and North Prussia into Russia, thence into Siberia, and so at intervals to the coast of the Pacific in Behring's Straits. The area is estimated at 4,500,000 square miles, a part of which is below the level of the ocean.

The parts of the plain strictly denominated *steppes* begin at the river Dnieper and extend along the shores of the Black Sea, including all the country north and east of the Caspian and the low lands of Siberia. Hundreds of leagues may be traversed eastwards of the Dnieper without variation of scene, and there is a dead level of thin but luxuriant pasture, bounded only by the horizon. While vegetation lasts, there are horses and cattle without number; but winter begins in October and the whole area is then covered with snow. Fearful storms of wind often rage when the sky is clear and bright. In June, the steppes are parched and the air is filled with dust; but at other times, and in many parts, wheat is cultivated, and the crops obtained are very large. On the whole, however, the steppes must be regarded as barren, and part of the tract is even a desert. Between the Caspian Sea and the sea of Aral there is for the most part a wide ocean of shifting sand, often driven by whirlwinds. [Aralo-Caspian Region.]

Stercorianism (Lat. stercus, stercoris, *refuse*). In Ecclesiastical History, a nickname which seems to have been applied in the Western church, in the fifth and sixth centuries, to those who held the opinion that a change took place in the substance of the consecrated elements, so as to render the divine body subject to the act of digestion.

Stercorite (Lat. stercus). An ammonio-phosphate of soda, occurring in crystalline masses and nodules in the guano of Ichaboe, on the west coast of Africa.

Sterculiaceæ (Sterculia, one of the genera). A large order of hypogynous Exogens belonging to the Malval alliance. They have the valvate calyx, contorted petals (sometimes wanting), and monadelphous stamens of *Malvaceæ*, but differ from them in their anthers being always two-celled. They consist of tropical South African or Australian herbs, shrubs, or trees, with alternate entire lobed or digitately compound leaves, furnished with stipules, and produce axillary or rarely terminal flowers, which are often large and handsome. The order has been variously extended or broken up into smaller ones by different botanists. Some include the *Bombaceæ*; but others refer these latter to the *Malvaceæ*, as having always one-celled anthers, and combine the *Byttneriaceæ* with *Sterculiaceæ*, dividing the order thus constituted into seven tribes: *Sterculieæ* proper—trees or shrubs, with unisexual flowers, no petals, five to fifteen anthers, adnate to the top of the column, and carpels distinct when in fruit; *Helictereæ*—trees or shrubs with hermaphrodite flowers, five petals, five to fifteen

anthers, singly or by twos or threes alternating with the teeth or lobes of the staminal column; *Eriolaneæ*, *Dombeyeæ*, *Lasiopetaleæ*, *Hermannieæ*, and *Byttnerieæ*, the latter group being frequently separated as the order *Byttneriaceæ*.

Sterelminthans (Gr. στερεός, *solid*, and ἕλμινς, *an intestinal worm*). The name of a class of internal parasitic animals or Entozoa, comprising those which are composed of a solid parenchymatous substance, in which the nutrient and generative canals are simply excavated, and not freely suspended in an abdominal cavity.

Stereo-electric Current. A term now rarely applied to the *thermo-electric* current which ensues when certain metals are brought into contact at different temperatures; it implies the production of a current of electricity in *solid bodies*, as opposed to the voltaic or *hydro-electric* current, in which fluids are essential.

Stereochrome Painting or **Stereochromy.** [WATER-GLASS.]

Stereognathus (Gr. στερεός, and γνάθος, *a jaw*). A genus of fossil mammalia, which has been discovered in the Middle Oolite, at Stonesfield. From the appearance of teeth, it has been inferred that it belonged to the Perissodactyle series, allied to *Hyracotherium* and *Pliolophus*, but it is of small size, and its exact position in the scale is not yet definitively ascertained.

Stereographic Projection. [PROJECTION OF THE SPHERE.]

Stereography. In Descriptive Geometry, the representation of solids on a plane.

Stereometer (Gr. στερεός, and μέτρον, *measure*). In Hydrodynamics, an instrument invented by M. Say, a French officer of engineers, for determining the specific gravity of liquid bodies, porous bodies, and powders, as well as of solids. The instrument may be

described as follows: Let A E be a glass tube, about three feet long, and open at both ends, the upper part A B being about $\frac{4}{10}$ and the lower $\frac{2}{10}$ of an inch in diameter. The upper edge is ground smooth, so that it can be shut air-tight by a piece of ground plate glass; and the upper part A B communicates with the lower by a very narrow slit at B, which allows air to pass, but prevents the passage of sand or water. In using the instrument, a powder (for instance) is placed in the tube A B, and the lower part B E is plunged into a vessel containing mercury till the fluid rises exactly to B. The ground glass cover is then placed upon the mouth A, and there is now no air in the tube except that which is mixed with the powder. Supposing the barometric pressure to be thirty inches; let the tube be elevated until the mercury stands within it at a point C, fifteen inches above its surface in the open vessel, and it is manifest that the air within the tube is pressed with exactly half an atmosphere. It consequently expands to twice its original bulk, and hence the tube A B now contains only half the quantity of air which it contained at first. The part B C must therefore contain the other half, or the air in B C is equal to the air mixed with the powder in A B; and being half the original quantity under half the original pressure, it fills the same space which the whole occupied previous to the expansion. Let the powder be now removed from A B, and the process repeated when the tube is filled with air. The quantity of air, being now greater, will, when expanded to twice its bulk, fill a larger space than B C, and the mercury will rise only to some point D; but as the expanded air occupies exactly the same space in B D or B C as the whole occupied in A B under twice the pressure, it follows that the cavity $CD = BD - BC$ is equal to the bulk of the solid matter in the powder. If, therefore, we now find the number of grains of water which would fill the part C D, we determine the weight of water equal in bulk to the solid matter in the powder; and by comparing this with the weight of the powder, we obtain its specific gravity. [HYDRODYNAMICS.]

Say's stereometer was first described in the *Annales de Chimie* for 1797. An instrument on exactly the same principle was afterwards brought forward by Sir John Leslie under the name of a *coniometer*. Although this instrument is simple and exact in principle, it could not in practice yield accurate results, without extraordinary precautions, on account of the great alterations in the bulk of the included air, caused by variation of temperature and even of barometric pressure during each experiment.

Stereoscope (Gr. στερεός, and σκοπέω, *I view*). The name given by Prof. Wheatstone to an instrument or apparatus proposed by him, and described in a paper on the Physiology of Vision, published in the *Philosophical Transactions* for 1838, for the purpose of exhibiting the effect of simultaneously presenting to each eye the projection of a solid body on a plane surface as it appears to that eye. To render this clear, it may be necessary to remark, that when a body of three dimensions is placed so near the eyes that, on looking at it, the optic axes must converge, a different perspective representation of it is seen by each eye; the body being, in fact, thus seen from two points of sight, at a distance from each other equal to the distance between the centres of the pupils, and the pictures of it projected on the two retinæ being consequently dissimilar. Supposing, then, two perspective drawings, on a plane surface, to have been made of an object as it is seen by each eye respectively; in order to try the experiment, it is necessary that the pictures be placed so that each can be seen by one eye only, and that the rays of light from the corresponding points of the two pictures fall on similar points of both retinæ, or enter the eyes in the same directions with the rays from the corresponding points of the original object. By reason of the small distance between the two eyes, this, manifestly, cannot be done without altering the direction of the rays.

For this purpose, Professor Wheatstone employed two small plane mirrors, about four inches square, adjusted at right angles to each other so as to form two adjacent sides of a cube, the faces being outwards. The edge where the two planes meet being brought close to the face of the observer, and the mirrors being placed symmetrically with respect to the direction of the visual rays, it is evident that if the two pictures be respectively placed before the mirrors symmetrically, and at equal distances, rays of light proceeding from them in opposite directions, and falling on the mirrors, will be reflected at right angles to their former directions, and become parallel. The right eye will see only the reflexion of the picture on the right-hand side, and the left eye that on the left-hand side; but on regarding both simultaneously, the mind readily unites the two images, and instead of the two plane pictures, an object of three dimensions makes its appearance, the exact counterpart of that from which the pictures were drawn standing out, as it were, in relief between the planes of the two mirrors.

In the *Report of the British Association for the Advancement of Science*, for 1849, Sir David Brewster states that, having had occasion to make numerous experiments on this subject, he was led to construct the stereoscope in several new forms. Of these forms, the most generally useful is the *lenticular stereoscope*. This instrument consists of two semilenses placed at such a distance that each eye sees the picture of a drawing opposite to it, through the margin of the semilens, or through points of it equidistant from the margin. The distance of the two portions of the lens through which we look must be equal to the distance of the centres of the pupils, which, at an average, is two and a half inches. By this method the images are not only united, but magnified at the same time, which is in many cases advantageous. The stereoscopes now so commonly used for viewing photographs taken from two different points of view are constructed on this principle.

Stereotype (Gr. *στερεός*, and *τύπος*, *an impression*). The surface of a page of types cast in one piece of type metal, about an eighth of an inch in thickness. The best kind are cast from a plaster mould, in which an exact representation of the types has been made, thus forming the permanent plates from which books are afterwards printed. As the art of PRINTING began with the impression of whole blocks, it may be said that in its progress towards perfection it has again reached the same point by the introduction of stereotype plates. The origin of the more modern invention is involved in greater obscurity than might at first sight appear probable from its comparatively recent date. By some writers the merit of the invention is ascribed to the Dutch, who had adopted the plan of printing with solid or fixed types in the seventeenth century; but it was not till the end of the last, and the commencement of the present century, that the process was perfected and generally introduced. In this useful invention, the most prominent names are Ged of Edinburgh, Tulloc and Foulis of Glasgow, Didot in Paris, and Wilson and Earl Stanhope in London.

Plaster of Paris Process.—The process of stereotyping by this process is very simple. A page of any work proposed to be stereotyped is set up with movable types, in the ordinary way. A plaster cast is then taken from it, which, being first dried, is immersed in fluid metal. The plaster used for forming the mould is pulverised gypsum, mixed with water to the consistence of cream. Lord Stanhope says, 'The best burnt gypsum mixes the most conveniently in the proportion of seven parts of water to nine of gypsum.' After the form of types has been surrounded with a brass frame, and slightly oiled on the surface, the fluid plaster is poured upon it, and, by the application of a brush, made to fill every cavity of the letters, the superfluous portion being scraped off. When the plaster has set sufficiently hard, it is by means of the frame lifted off the face of the type and detached from it. It is then baked to dryness in an oven; and when quite hot it is placed in an iron box or casting pot, which has also been heated in an oven. The box is now plunged into a large pot of melted type metal, and kept about ten minutes under the surface, in order that the weight of the metal may force it into all the finer parts of the letters. The whole is then cooled; the mould is broken and washed off; and the back of the plate turned smooth on a lathe, or planed by a machine. The cast or plate, after being sufficiently cooled, is carefully examined with a view to removing any imperfections previous to its being printed from.

Papier-mâché Process.—In stereotyping, a new method has of late years been introduced from Paris. On the face of the type is laid a mould consisting of six or seven sheets of fine tissue paper, gummed together and moistened; the outside sheet being of a stouter paper. The whole is then struck regularly and carefully with a large flat brush of hard bristles, till the moistened paper has received an impression of the type, &c. beneath. The mould is then dried on a hot iron table, a blanket being laid over it to absorb the moisture, and screwed down moderately tight to prevent it from warping. When sufficiently dry, which it becomes in a very few minutes, it is ready for the stereotype cast. This is taken in an ingeniously contrived mould, by which the size and thickness of the plate, whatever they may be, are regulated. The mould has not then to be destroyed, as in plaster casting, but is removed, either to reproduce other casts immediately, or to be reserved for future use. This is of great advantage in the case of cheap publications or rough works of which reprints are often required, as

the moulds are light, and involve no expense in keeping.

Newspaper Stereotyping.—The stereotyping process by which the rapid printing of newspapers is effected is an improvement hardly inferior to that by which the late Mr. Walter applied steam power to the printing press, and certainly equal to that by which the rotary press superseded the reciprocating action of the flat machine. It was commenced, and has been elaborated to the point now reached, by the present Mr. Walter, at the *Times* office. He began his experiments, aided by an Italian founder named Dellagana, in 1856, when, by papier-mâché matrices, rapidly dried and placed in a mould, columns were cast in stereotype metal, type high, planed flat, and finished with sufficient speed to get up the duplicate of a form of four pages, which was worked off on a spare flat machine—the speed at which the *Times* had previously been published being thus accelerated by nearly 5,000 impressions per hour. The next step taken was to adapt these type-high columns to the Applegath presses, then worked with polygonal chases. That step raised the previous 5,000 to 10,000 per hour; but though the publication of the *Times* was thus finished in much less time than before, it soon became clear that the process could be greatly simplified in its details, and extended and improved in its application. Accordingly, shortly after the introduction of Hoe's machines, instead of dealing with separate columns, the papier-mâché matrix was taken from the whole page at one operation by beating in the matrix with brushes. The matrix, rapidly dried on heating surfaces, was then accurately adjusted in a casting machine curved to the exact circumference of the main drum of the machines, and fitted so as to secure a casting, as nearly as possible, of uniform thickness. On pouring stereotype metal into this mould, a curved plate was obtained, which after undergoing a certain amount of trimming at two machines, specially made for the purpose, one for squaring the plate while being picked, the other for planing the back, could be taken to press and set to work within twenty-five minutes from the time at which the process began. A still further improvement has been made at the *Times* office, by which less injury is occasioned to the type than by the process of beating in the matrix with brushes, saving the serifs of the letter from being broken, and giving a more uniform face to the plate; viz. by the use of roller presses, somewhat similar to an iron copperplate press. The printing obtained from these plates was as good as that from pages of movable type. All the risk, and inconvenience, and wear and tear attending the imposition of these pages in curved chases—the placing them on the presses—and subjecting them to the destructive friction of the machining process—were at once obviated. The fount, instead of wearing out every two years, might last for several, the present fount having been in use nearly seven years. The plates after doing their work for one day could be melted down the next into a new impression, and (most important of all) the original type page, safe itself from all chance of injury, could be made to yield any number of copies that might be required by the exigencies of the circulation, and which there were spare machines to work. Thus has it come about that the inner or news sheet of the *Times* is now printed every morning—stoppages included, at the rate of 52,000 impressions per hour—the two American machines yielding 16,000 each, and the two Applegath 10,000 each. Between three and five o'clock every morning there are cast and finished in the foundry of the *Times* office, four complete sets of each page of the news sheet—i. e. a quadruple of the eight pages—or thirty-two pages in all. Mr. Walter has applied steam power to the operations of the foundry, which, though still capable of considerable improvement, are now accomplished with great ease and certainty of result. It is obvious that by the multiplication of stereotype plates and machines there is practically no limit to the number of copies of a newspaper which might be printed within the time the process now usually occupies.

Sterlet. A small kind of sturgeon, the *Acipenser Ruthenus* of Linnæus. The larger kind occasionally taken in Britain is the sturgeon proper, *Acipenser Sturio*, &c.

Sterling. The legal description of the English current coin, of which the most probable derivation is from *Easterling*, the popular name of the Baltic and German traders who visited London in the middle ages; but in what manner it came to be so applied is unknown. Camden attributes it to the employment of German artists in coining. The silver penny was first called Easterling.

Stern (A.-Sax. steor-ern). In Naval affairs, the after extremity of a vessel.

Stern-post. An upright timber rising almost at a right angle from the after end of the keel, into which it is tenoned. It forms the after end of the ship, receiving the buts of the planking and being that part to which the rudder is usually hung.

Sterna. A genus of web-footed birds, having a bill as long as or longer than the head, almost straight, compressed, and pointed; the mandibles of equal length, the upper one slightly inclined towards the point; nostrils pierced towards the middle of the bill; legs small, naked to above the knee; three anterior toes, united by an indented web; the hind toe free; wings very long and pointed; tail more or less forked. From the two latter characters, the species of *Sterna* are sometimes called *sea swallows*: their proper English name is *tern*.

Sternbergite. Flexible sulphide of silver and iron, composed of 30·38 per cent. of sulphur, 34·18 silver, and 35·44 iron. It generally occurs in implanted rhombic crystals, which are attached to the matrix laterally, so as to form rose-like or fan-like aggregations; also massive. It is of a pinchbeck brown colour, with a violet-blue tarnish; is very sectile, and flexible in thin laminæ, which after being bent may be

smoothed down again with the nail, like tin-foil. It is found in Bohemia, Hungary, and Saxony. Named after Count Caspar Sternberg.

Sternoxi (Gr. στέρνον, *the breast*, and ὀξύς, *pointed*). The name of a tribe of Coleopterous insects, comprehending those in which the sternum is prolonged into a point at both extremities.

Sternson. A timber bearing the same relation to the stern-post which the stemson bears to the stem.

Sternum (Gr. στέρνον). In Comparative Anatomy, the simple or compound bone which completes the thoracic cage anteriorly, and serves as a medium of union to a greater or less number of the ribs. The sternum is not present in the skeleton of Fishes, Amphibians, or Ophidians. In Saurians, the anterior portion is generally expanded, to be joined to the broad coracoids and clavicles. In Chelonians, this part of the skeleton is remarkably developed, and very complex, and constitutes the greater part of the plastron or floor of their defensive osseous case. In Birds, also, it is more or less complex at the beginning of its developement; but the different ossifications are soon blended together, and form a single broad bone, principally remarkable for the keel-like process developed from the middle line of its under surface. This keel is subservient to the attachment of the muscles of the wing, and bears a direct proportion to the powers of flight; except where the wings, as in the penguin, are used as fins. In the Struthious birds, the keel of the sternum is wanting.

In Mammalia, the sternum is generally simple, and consists of a single chain of ossicles; except in the orang-utan, and occasionally in man, where a double series of ossifications are originally developed in the body of the bone, but which afterwards become confluent. The upper portion, or *manubrium sterni*, remains long distinct from the main body of the sternum; in man, the cartilaginous appendage of the lower edge of the sternum is called *xiphoid* or *ensiform*.

Stethoscope (Gr. στῆθος, *the chest*, and σκοπέω, *I explore*). A cylinder of cedar wood or other material, about twelve inches long, and one inch in diameter; perforated throughout its length. It is occasionally divided into two parts for the convenience of using the whole or half its length. The end of one part terminates in a funnel-shaped cavity; the other end, which is applied to the ear during auscultation of the chest, varies in shape according to the fancy of the physician. It is usually in the form of a disc, more or less hollowed out and rounded at the edges to receive the ear conveniently. One great use of this instrument consists in its allowing the auscultator to examine over small portions of lung at a time, and so detect more correctly than by the naked ear the exact part or parts affected by disease. [AUSCULTATION.]

Stevedore or **Stivadore.** In Merchant Shipping, the officer whose business it is to superintend the stowage of ships. Maclachlan, in his *Laws of Merchant Shipping*, says that the *Consolato del Mare*, an ancient collection of maritime laws, mentions an officer called *stibador* (Lat. stipator, *an attendant*), from which the English term is probably taken. Young's *Nautical Dictionary*.)

Steward. In Feudal Law, the lord's deputy or seneschal in the MANOR COURT, who presided over the business transacted in the court.

STEWARD. On Shipboard, a petty officer charged with the details of the preparation and arrangements of the officers' mess.

Steward, Lord High. The Lord High Steward was anciently the first officer of the crown in England, with the Latin title of Magnus Seneschallus. The office was at one period annexed to the lordship of Hinckley, in Leicestershire, held by the family of De Montfort; but on the fall of that noble house, it was in effect abolished as a permanent dignity, and is now only revived pro hâc vice on the occasion of a coronation, or the trial of a peer. In the former case, the lord high steward's commission is to settle matters of precedence, &c.; in the latter, to preside in the House of Lords.

In accordance with the feudal theory, the whole of England, as respected the crown, was treated as one great manor, the lord of which was the king; the great peers constituted the court baron; the lord high steward was the seneschal. Just as in the manor court, the initiative in a criminal or civil action could not be taken except on the presentment of the homage, or in the view of frankpledge, so no judgment against a peer could be instituted except by the action of the peerage. And, similarly, as in a manor court the proceeds or profits of fines and forfeitures became the right of the lord, so the offence of a peer resulted in a forfeiture to the crown. And again, as in the case of private manors, the loss of the high jurisdiction ensued from the necessity of pleading the privilege of the manor, and the ordinary police of the manor has fallen into desuetude from the same reason, so the house of peers has retained its special jurisdiction over its members, by virtue of the fact that parliament is itself a court of record of the highest kind, and therefore its jurisdiction could neither be forgotten, ignored, nor disputed. Judgment, in short, by peers did not originally mean the impanelling of a petty jury before a justice in eyre, but the right which every freeholder had, and, before long, every villein, of a legal trial before the jury of the manor in which he lived or his land was situate, or the offence with which he was charged was committed.

As might be expected, the steward's judicial functions have lasted longer in corporations than in any other localities. The successor of the steward in ordinary or municipal corporations appears to be the recorder; but the two universities have still each their high steward,

who is empowered to try felonies committed by privileged persons, and probably on privileged persons, within the verge of the academical liberties; and as the chancellor of the university answers to the lord of the ordinary manor, so the seneschal or high steward is his deputy, and appointed by him.

Steward, Lord, of the Household. An officer of the sovereign's household in England; in Norman French, *seneschal*. The principal officers of the lord steward's department are the treasurer of the household, the comptroller of the household, the master of the household, and the secretary of the *board of green cloth*, a body composed of the above-mentioned officials, who formerly exercised jurisdiction of offences committed within the verge of the court, but whose duties are now confined to the supervision of the household accounts, the government of the household servants, &c. The lord steward was the nominal head of the Court of the Marshalsea and the Palace Court until their abolition.

Steward of a Manor. In Law, the lord's deputy, who transacts all legal business in connection with the estate, and has custody of the court rolls. [COPYHOLD; MANOR.]

Sthenic Diseases (Gr. σθένος, *strength*). Those diseases which are the result of inflammatory or increased action; as opposed to asthenic, or diseases of debility.

Stibethyl. A combination of one atom of antimony and three of ethyl. It may be regarded as ammonia in which the nitrogen is replaced by antimony and the hydrogen by ethyl.

Stibiconise (Gr. στίβι or στίμμι, and κόνις, *powder*). A hydrated antimonious acid, which occurs in amorphous earthy masses of a yellow, grey, or brownish colour at Trewinnick, near Endellion, in Cornwall, and in various foreign localities.

Stibium (Lat.). Antimony. [STIBNITE.]

Stiblite. [STIBICONISE.]

Stibnite (Lat. stibium). Native tersulphide of antimony; composed, when pure, of 72·88 per cent. of antimony, and 27·12 sulphur. It usually occurs in long prismatic or acicular crystals, or in a fibrous form, of a lead-grey colour inclining to steel-grey, and sometimes with an iridescent tarnish. It is found in Cornwall, Cumberland, Scotland, and in several foreign localities, and is the ore from which most of the antimony of commerce is obtained. For the uses to which it was applied by the ancients, see Bristow's *Glossary of Mineralogy*, p. 362-3.

Stichomancy (Gr. στίχος, *a line*; μαντεία, *prophecy*). [SORTES.]

Stick, Gold. The colonels of the two regiments of Life Guards are so called, whose duty it is to be in immediate attendance on the sovereign on all state occasions. These colonels do duty for a month alternately; the one on duty being called the *gold stick in waiting*. The field officer of the Life Guards who is on duty is called *silver stick*. The term originated in the custom of the sovereign presenting the colonel of the Life Guards with a gold stick on his receiving the regiment.

Stigma (Gr. *a mark*). An impression such as that made by branding with a hot iron. Stigmatising was a common practice among the ancients to mark their slaves as property; and it is pursued at the present day among slave-drivers. It was customary also to stigmatise the votaries of some of the gods with some recognised emblem of their divinity, such as the ivy of Bacchus, the trident of Poseidon, &c.; or with the initial of their names, or some mystical number. It is supposed that reference is made to this practice in Rev. xiii. [TATTOOING.]

STIGMA. In Botany, the upper extremity of the style without a cuticle, in consequence of which it has almost uniformly a humid and papillose surface. It is the part upon which the pollen, when it falls thereon, is stimulated into the production of the pollen tubes, which are indispensable to the act of impregnation.

Stigmata (Gr.). In Theological language, the marks of the wounds of Jesus on the cross. The text at the end of the Epistle to the Galatians, 'From henceforth let no man trouble me: for I bear in my body the marks of the Lord Jesus,' seems to have given rise to the notions promulgated in the Roman Catholic church respecting the impression of the stigmata on favoured saints; of which the legend of St. Francis of Assisi affords the most remarkable instance.

Stigmite. [ST. STEPHEN'S STONE.]

Stilaginaceae (Stilago, one of the genera). A name originally proposed by Agardh for a small group of genera, including *Antidesma*, whose affinities had been little understood. Lindley places them as an order of Diclinous Exogens, in the Urtical alliance. By others they have been included in the large order *Euphorbiaceæ*, an arrangement which appears to be generally adopted.

Stilbaceae (Stilbe, one of the genera). A small order of monopetalous perigynous Exogens, whose immediate affinities are very uncertain. The order is usually placed near *Verbenaceæ* and *Selaginaceæ*, but Lindley regards it as more nearly allied to *Diapensiaceæ*. It consists of South African shrubs, with small crowded heath-like leaves, sessile unsymmetrical flowers in dense terminal spikes, a simple stigma, axile placentæ, and definite erect seeds.

Stilbene (Gr. στίλβω, *I shine*). A peculiar hydrocarbon, which crystallises in scales of a pearly lustre.

Stilbite. An anhydrous lime-oligoclase, composed of 58·2 per cent. of silica, 16·1 alumina, 8·8 lime, and 16·9 water. It generally occurs in broad prismatic crystals, clustered into sheaf-like aggregations and diverging groups; also massive and in fibrous aggregates. It is white, but sometimes yellow, grey, red, or brown, with a vitreous lustre, and is translucent to transparent at the edges. The principal localities in the United Kingdom are Cornwall, between

Botallack and Huel Cock; Isle of Arran, in granite; Campsie and Fintry, Stirlingshire, in porphyritic amygdaloid; in Ireland, at the Giant's Causeway, in geodes; Mourne Mountains in granite.

Stilbite is called by the German mineralogists *Desmine*; the mineral termed by them Stilbite being the *Heulandite* of English mineralogists.

Still (Lat. stillare, *to drop*). An apparatus for the distillation of liquids upon the large scale. It includes the *body*, or *boiler*, which is usually set in brickwork over a furnace, and to which is annexed the *head*, forming the communication between the boiler and *condenser* or *worm pipe*; from the extremity of which the distilled liquid passes in successive drops, or a small continuous stream, into the *recipient*. There are an infinite variety of stills adapted to particular purposes, of which the most important are the distillation of spirituous liquors. (Ure's *Dictionary of Arts, &c.*)

Still Life. In Painting, dead game, arranged fruit or flowers, silver, glass, china, and, in fact, any inanimate or *still* object.

Stillingia (after Benjamin Stillingfleet). A genus of *Euphorbiaceæ*, of which the Tallow-tree, *S. sebifera*, is the best known representative. This tree is a native of China and the adjacent islands, but has been introduced into and partly naturalised in India and the warm parts of America. It has rhomboid leaves with two prominent glands at the point of attachment between the stalk and leaf; and its flower-catkins are from two to four inches long. Its fruits contain three seeds thickly coated with a fatty substance which yields the tallow. This is obtained by steaming the seeds in large caldrons, and then bruising them sufficiently to loosen the fat without breaking the seeds, which are removed by sifting. The fat is afterwards made into flat circular cakes, and pressed in a wedge-press, when the pure tallow exudes in a liquid state, and soon hardens into a white brittle mass. This tallow is very extensively used for candle-making in China; but as the candles made of it become soft in hot weather, they generally receive a coating of insect-wax. A liquid oil is obtained from the seeds by pressing. The tree yields a hard wood used by the Chinese for printing blocks, and its leaves are employed for dyeing black.

Stilpnomelane (Gr. στιλπνός, *shining*, and μέλας, *black*). A hydrated silicate of alumina and protoxide of iron, which occurs in blackish-green masses, with a granular or radiating and foliated structure in the clay-slate of Zuckmantel in Austrian Silesia.

Stilpnosiderite (Gr. στιλπνός, and σίδηρος, *iron*). A hydrated peroxide of iron, referred by Ullman to Limonite, and by Von Kobell to Göthite. It occurs massive, or in stalactitic, botryoidal, and dendritic forms, varying from blackish-brown to pitch-black, at Tincroft in Cornwall, and in Saxony, the Harz, Bavaria and Siegen in Prussia.

Stilt Bird. The name of the *Himantopus melanopterus*, significative of its very long and slender legs.

Stimmi (Gr.). An ancient name of the sulphide of antimony. [STIBIUM.]

Stink Wood. The useful timber of *Oreodaphne bullata*, which possesses a durable and most unpleasant odour.

Stinkstone. A bituminous carbonate of lime, which exhales a fetid smell, like that of sulphuretted hydrogen gas, when rubbed or crushed. The limestones of the Purbeck and Portland formations of Dorsetshire, and the Mountain Limestone of Matlock, the Bristol Coalfield, and Sunderland, are examples of this kind of stone. It is stated by Prof. T. B. Jukes (*Manual of Geology*, 2nd edition, p. 145), that 'some of the limestone quarries in the Carboniferous Limestone of Ireland may be smelt at a distance of a hundred yards, when the men are at work.'

Stint. In Coal Mines, a measure of work used under ground, 2 yards long and 1 broad, which each miner clears before he removes to another place, and which is proved by a boy appointed for the purpose, who is colloquially called *the judge*.

Stipend (Lat. stipendium). This word signified originally the pay of soldiers. In a legal sense, it is applied to the salary or allowance given to some person for transacting the business of another; but in Scotland the term is almost exclusively confined to the provision made by law for the established clergy. [PRESBYTERY.]

Stipes (Lat. *the trunk of a tree*). In Botany, the stalk of a fern leaf; also the stem which supports the pileus in such fungi as Agarics.

Stippling. In Engraving, the method of producing shadows by means of dots of greater or less size, according to the intensity of shadow required. By this method the resemblance to chalk drawings is produced.

Stipule (Lat. stipula, *a stem of corn, stubble*). In Botany, a small appendage situated upon each side of the base of a petiole, most commonly of a less firm texture than the latter, and having a subulate termination. The word is also used in describing *Hepaticæ*, to denote the appendages which are occasionally present at the bases of the leaves, but of which they seem rather to be lobes than distinct organs.

Stirrups (A.-Sax. stige-rapa). On Shipboard, short ropes, pendent from the yards, and having eyes through which the horse passes, on which the sailors stand, when furling or unfurling the sail.

Stivadore. [STEVEDORE.]

Stiver. A Dutch coin, of the value of an English halfpenny.

Stoat. In common use, a synonym of *weasel* (*Putorius vulgaris*), but by British zoologists restricted to the larger variety, with a tendency to turn white in winter, at which season, in colder climates, it affords the valuable fur called *ermine*. By some this is held to be a distinct species (*Putorius erminea*).

Stock. In the phraseology of Agriculturists, the animals maintained on the farm are called *live stock*, the implements and carriages *dead stock*. This distinction is very ancient, being familiar to those who study mediæval records under the names of *staurum vivum* and *staurum mortuum*.

The amount of live stock which can be maintained on a farm is a question of great interest to the farmer, and must be determined by the peculiar character of the land which he cultivates, though of course it is possible by high farming, and especially by farming on lease, to increase the number of animals kept. But it is also of great importance to the public to know what is the ordinary amount of stock kept in the country, for its plenty or scarcity determines the supply of meat. Up to the present year (1866) no information on this subject has been supplied from Great Britain, though statistics have been given from Ireland for some years past. The returns which have been given this year were almost necessitated by the compensation clauses of the Cattle Plague Act. These compensation clauses were not defensible on grounds of common justice, for the losses of those whose cattle perished were more than countervailed by the rise in the price of those which survived, in accordance with a law noticed in the article Price, but they would have been utterly intolerable had there not been a statement of the proportion which the deaths by plague bore to the existing states. The numbers of the cattle kept in each European community of importance and in the United States are given below. The population and the returns of live stock are taken from the latest returns.

The table of statistics giving information of the amount of cattle, sheep, and pigs on March 5, 1866 (on the presumption that the returns are accurate), is singularly instructive. In drawing any inference on this subject, we should treat Great Britain separately from Ireland, as the importation of cattle from this part of the United Kingdom is more difficult than it would be from Belgium or France, and nearly as difficult as from Denmark and the Elbe. In round numbers, the population of Great Britain is about 24,000,000.

In one particular only, that of sheep, is Great Britain on a general level with other countries. There is nearly a sheep to every head of population. But of horned cattle there is only one to about every five; of pigs, only one to every nine. Were the amount of horned cattle in France proportionate only to that of Great Britain, France would have a little more than 6,000,000; in fact, it has rather more than 14,000,000. The same may be said of Austria. In many of the German states the proportion is higher still. In Denmark the cattle are not very much less numerous than the population. In the United States there is rather more than one head to every two of population. In France and Prussia, pigs are one to seven; in Austria, one to four and a half. Taking the whole of Europe, the proportion is one to six. In the United States there are more pigs than population.

Had the returns supplied us with information as to poultry, the deficiency of Great Britain would have been still more striking. In the year 1865 this country imported more than 400,000,000 eggs, if the hundred of eggs be taken, as it has been from the earliest time, at 120.

This deficiency is not greatly supplemented by importation. Small as the stock of cattle is, the annual importations do not amount to more than one-twentieth of the ordinary stock, while that of sheep is, as a rule, but one-fiftieth. During the present year even these quantities must have undergone a serious diminution. Nor is the import of meat large. The most important item is that of bacon. But even here the largest estimate will not give more than the equivalent of 300,000 pigs. The beef seems to be about equal to the supply of 50,000 oxen.

It is a matter of regret that no facts have been collected by which we might compare the past and present supply of live stock in Great Britain. It is, of course, always dangerous to trust to impressions, or to memory; but we cannot but be convinced that there has been a general and considerable diminution in the amount of live stock in Great Britain for some years past. It is now comparatively seldom that agricultural labourers are able to keep pigs; it is still more rare that they breed poultry. The enormous importation of eggs suggests that the fowls kept in Great Britain are comparatively scanty. But it is probable that the maintenance of insect-eating birds is an important provision in agricultural economy, and that when we find fault with the destruction of small birds, we forget that our practice is dispensing with a still more important means for checking the ravages of insects, as well as for supplying that great deficiency in live stock which seems to characterise our domestic economy. It is possible, too, that the abandonment of much pasture in the northern part of the island to deer forests and grouse moors has considerably lessened stocks of lean cattle and mountain sheep.

Stock. In Finance and Political Economy, a term employed to denote capital which has been expended by the owner, in the course of his business, or subscribed to a joint fund, to be managed by directors, or lent to the government on behalf of the nation, with the view either of carrying out public works, or of serving as a fund for carrying on warlike operations.

The first of these sources will be familiar to the readers of Adam Smith, with whom *stock* is frequently employed as a synonym for *capital*. This usage is, however, nearly obsolete at present. The second and third are more familiar, and are related. In the beginning of those commercial adventures which were created by charters and secured by a monopoly, the parties subscribing were held to possess stock in proportion to the amount to which they pledged their names or credit, and the earliest stocks were those of the East India Company, the African and Russia Companies, and the Bank of England. In most of these cases, the company was said to be regulated.

When public debts were created, or (to be more correct) when such debts were secured by parliamentary pledges, and were therefore guaranteed, the sum subscribed was, in imitation of those older arrangements, called a *stock*, particular sources of public income being pledged for the payment of the interest, and in many cases for the repayment of the principal. In course of time [National Debt], these separate funds were formed into one, called *consolidated stock*, a term which has been gradually abbreviated into *consols*.

In later times, the word *stock* has been used specifically to designate any subscribed capital which is divisible into optional parcels, and which is therefore contrasted with *shares*. When a trading company, as, for instance, a bank, railway, or any similar public undertaking, is constructed, it is, or has been, customary to raise the necessary capital by the issue of shares of greater or less amounts. These shares, as long as they are called by this name, are, as a rule, indivisible. When, however, as in many cases, it is more convenient to allow purchasers to choose their own quantity, the shares are converted into stock. As a rule, capital held as stock passes more freely from hand to hand, and is therefore more marketable; but it is, on the other hand, more liable to fluctuations in value.

Stock Dove (stock, in the sense of a tree-stem). The name of the wild species called *Columba Œnas* by Linnæus. It frequently breeds in leafy pollards, called *stocks*.

Stock Exchange. The mart in which public and private securities are negotiated and bargained for. The word generally used in foreign countries as an equivalent is *bourse*. Since the Revolution, and the parliamentary guarantee of public debts, dealings in the stocks, which compose the corpus of such debts, either on the dealer's behalf, as speculator, or for some other person as broker, are obvious and inevitable; and as the disposition to speculate or risk, or, as some may be pleased to say, gamble, is almost innate in men, it is not remarkable that from the earliest days in which stocks were regularly saleable, there should have arisen a class of men who made it their business to watch the turns of the market and the feelings of the public, with a view to making a profit out of transactions which do not represent real sales or purchases, but only the risks of the market, or, as they are technically called, *time bargains*. This traffic in course of time was extended to other stocks than the public funds; and jobbers, as they were called with some tinge of disapprobation, made every conceivable article of value, and very often every conceivable contingency, a subject for such transactions. Thus, for instance, we are told that the life of the first Napoleon was perpetually speculated on, and that the insurance on his life for the single year 1804 was often more than fifty per cent.

At first these stock exchange speculations were held in the Royal Exchange; but in 1698 the jobbers removed to Change Alley, at that time a large open space, and carried on their speculations without discrimination of persons, on the principle, in short, of a public betting ring, or of such gatherings of gamblers as used till lately to congregate in St. Bride's Passage, and afterwards on the vacant space near Farringdon Street. In a short time, the superior members of the fraternity took up their quarters in Jonathan's coffee-house. Afterwards there was a new Jonathan's as well as an old; and these places were the home of the stock jobber for a century.

After the brokers had quitted the Royal Exchange, the corporation of the city strove to recall them, and in order to secure their return inscribed a clause in the broker's bond—brokers, in pursuance of an Act of William III., being licensed and regulated by the corporation—to the effect that they should carry on their business in the Royal Exchange. This clause, though long continued, was never operative.

The occupation of a jobber was always looked on with disfavour by the general public and the stricter men of business, and discountenanced, in appearance at least, by the houses of parliament. We say in appearance, for some of the worst cases of dishonesty on the Stock Exchange, as, for instance, that of the South Sea Scheme in 1720, were clearly traceable to members of the legislature. These gentlemen passed Acts perpetually against transactions in which they were deeply concerned, and by which they were in many cases seriously compromised. The Acts of 7 & 10 George II., commonly called Sir John Barnard's Acts, had a different origin. Sir John Barnard hoped to check the practice of time bargains by making such Stock Exchange debts irrecoverable, and for a time the author of the enactment was reputed to have gained his end, and certainly he earned the unmixed hatred of the stock jobbers. But they devised a means of

escape through the machinery of an internal and voluntary police; and within a very short time after their passing, these Acts became wholly inoperative, and in all probability Stock Exchange bargains were met more punctually and regularly than any other liabilities. Sir John Barnard's Act, long obsolete, was repealed a few years ago.

Stock Exchange transactions were treated rigorously as debts of honour; and defaulters, called in the grotesque language of the Exchange *lame ducks,* were peremptorily excluded from the alley. In 1787, in consequence, it seems, of some extraordinary irregularities, it became the custom to exhibit the names of defaulters on a black board. The members of the fraternity were too cautious to expose themselves to the risks of libel, in case some expelled member, on whom this curious sentence was inflicted, thought proper to seek a remedy in a court of law. Nothing, we are informed, could be more innocuous than the outer shape of a fiat of expulsion from the privileges of a broker or jobber. It was simply couched in these words: 'Any member with whom A B (the defaulter) does business is requested to communicate with C D.' The police of the Stock Exchange is vested in a committee of twenty-eight, whose power is absolute, and whose sentence is final, and no person can be deprived of his privilege by a less number than twelve members of the committee. In the new Stock Exchange, the first stone of which was laid in 1801, the members are elected by ballot, and pay an annual subscription of ten guineas. They are also required to find security to a certain amount for some years, and the most energetic measures are taken against any stranger who even inadvertently enters the precinct.

All important stocks are quoted on the Exchange, and the rates at which they are bought and sold are given in the daily papers. It is understood that the quotation of a stock on the Exchange is a considerable advantage to it, and the brokers have exercised a wholesome discipline not only over defaulting jobbers, but over dishonest governments, by excluding their securities from the public market. The most absolute monarch is, in these days of public debts, kept in awe by the committee of the Stock Exchange, for a sentence of exclusion from its bargains is almost fatal to any future financial projects. In ordinary commercial stocks, especially in joint-stock companies for trading purposes, the privilege of quotation on the Exchange is frequently bargained for at a considerable sum with leading brokers, partly that the stock may secure the advantage of an open market, partly that it may be placed, or taken up by buyers of shares.

As the committee of the Stock Exchange attempt to regulate by an internal police the commercial good faith of the brokers, so they are bound, as the society virtually possesses a monopoly of the trade in securities, to check unfair practices against the public. On this point, however, they are less sensitive; and it may be doubted whether the real influence of the Stock Exchange, and the importance attached by the promoters of joint-stock companies to Stock Exchange quotations, have not suffered a severe shock by the intrigues of a few members of that body against joint-stock banks. During the present year (1866) it is plain that attempts have been made on the part of some persons connected with the Exchange to depreciate existing shares, and this has been carried to such an extent as to destroy property in some cases, and considerably depress its value in others. Of course such attempts spring from the practice of making time bargains, a practice coeval with a stock exchange, and inseparably connected with it; but if the custom at a particular crisis becomes a conspiracy, and a serious public evil, the remedy should be provided at the hands of those who are interested in the reputation, and so in the public usefulness, of the Exchange.

On the whole, negotiations on the Stock Exchange, even when of a purely speculative character, subserve (like the trade of a corn dealer) a considerable public benefit. The eagerness with which a corn dealer watches the market for a rise or fall tends to equalise prices, and, more important still, to economise resources in times of dearth and plenty. Similarly, the speculations of the stock and share broker obviate excessive fluctuations in the price of securities. Were it not for these agencies, a slight distrust felt about any stock might induce a panic among the general public, or irrational confidence an undue exaltation in its market value. The stock broker, buying when the former case is likely to occur on insufficient grounds, arrests the fall, and by selling when the latter motive is operative, checks the rise. There can be no doubt, that with so vast an amount of subscribed capital in the market, amounting certainly to not less than 2,000 millions, the variations in the value of these stocks would be infinitely greater, and the effects of confidence and panic incomparably more disastrous, if it were not for the jobbers and speculators on the Stock Exchange.

The language of the Stock Exchange is eminently metaphorical. The explanation of some of these terms has been given by Mr. Francis, whose *Chronicles and Anecdotes of the Stock Exchange* is a very amusing and instructive work. The writer of this article has been indebted to it for some of the historical facts quoted above.

Bull: a person who buys stock on account, not intending to hold it, but simply, at a date agreed on between the dealers, to pay or receive the difference between the price at which he values it, and that at which it actually stands on the day specified.

Bear: a person who sells stock on account on the same terms, and with the same purpose.

Lame Duck: a defaulter at the settlement of such bargains, whose name is exposed on the pillory of the Stock Exchange, the dreaded black board.

Backardation: a consideration given to keep back the delivery of stock, when the price is lower for time than for money.

Continuation or *contango* is the premium given when the price of funds in which a person has a jobbing account open, is higher for time than for money, and the settling day is arrived, so that the stock must be taken at a disadvantage. In this case a per-centage is paid to put off the settlement and continue the account open.

Jobber: a term applied to those who accommodate buyers and sellers of stock with any desired quantity.

For information as to the commercial history of many eminent members of the Stock Exchange, see the work above referred to.

Stocks. A well-known kind of punishment. The practice of confining men by the legs was so common as to have given the ordinary name to a chain of any kind in several languages: e.g. Gr. πέδη, Lat. compes, Eng. fetter; all from πούς, pes, *foot*. The stocks in England have been, generally speaking, used rather for restraint than punishment, constables being empowered to put disorderly persons into them; but this penalty was likewise ordered by some statutes as a punishment on conviction. It is now disused.

Stocks and Dies. The iron handle which receives the *die* that cuts the path or the thread of a screw, is known by the name of a *stock*. It is generally made so as to accommodate a great variety of the dies employed in such cases.

Stockade (Fr. estocade, Ital. stoccato). In Civil Engineering, stockades are sometimes used in defences of the seashore against the sea, or for the banks of rivers exposed to the erosion of the current; but the best protection against the current is brushwood with the branches pointing upwards against the stream.

STOCKADE. In Fortification, a strong timber wall, eight or nine feet high, loopholed for musketry fire, and sometimes having a ditch in front, and banquette in rear.

Stocking. A garment for the foot and leg. Stockings were at first made of cloth or of milled strips sewn together. Silk-knit stockings seem to have been introduced from Spain in the sixteenth century. Knit stockings are wrought with needles made of polished iron or brass wire, which interweave the threads and form the meshes of which the stocking consists. Woven stockings are manufactured on a frame of polished iron, which was invented towards the close of the sixteenth century.

Stoics. A celebrated sect of antiquity; so called from the *stoa* or *porch* in Athens, which was the scene of the discourses of their founder Zeno (B.C. 300). The Stoics are proverbially known for the sternness and austerity of their ethical doctrines, and for the influence which their tenets exercised over some of the noblest spirits of antiquity. To give a connected and systematic account of the philosophical principles on which they grounded their moral precepts is a less easy task than, from the notoriety of the latter in some of their main features, might have been anticipated. Their speculations were not confined to ethical subjects, but aimed at embracing the whole circle of human knowledge; physics, theology, and logic, no less than morals and politics. Their system, as far as we can gather from the notices preserved by Cicero, Diogenes, and others, appears to be an attempt to reconcile a theological pantheism and a materialist psychology with a logic which seeks the foundations of knowledge in sensible experience, and a morality which claims as its first principle the absolute freedom of the human will. Of the mode in which they combined dogmas apparently so inconsistent into a philosophical whole, we have accounts sufficient to inspire us with respect for the earnestness and strength of character possessed by the leaders of their sect, and with admiration of their subtlety, ingenuity, and depth. We discern, at the same time, in all their speculations, equally a narrow and controversial spirit, very unlike the critical but comprehensive impartiality which marks the philosophical writings of their great predecessors—of Plato, and, in a still more eminent degree, of Aristotle. The philosophy of the Stoics was essentially polemical. On every side it presented an armed front to an opponent. It sought to confute the academic scepticism by the strenuous assertion of the truth of sensible perceptions, and the validity of the judgments to which they lead by a vigorous protest in favour of the common sense of mankind as opposed to the theories of the schools. Sensation, they affirmed, is not merely a passive affection of the mind; it becomes, under certain conditions, perception or *comprehension* (κατάληψις), a faculty whereby the mind reaches beyond itself, and *lays hold*, as it were, on outward being. From the acquisitions of sensible experience are formed conceptions and judgments of successive stages of generality, which it is the province of the reason to construct into philosophical system. Such is the stoical logic, which is consequently a *material*, and not, as with Aristotle, a *formal* science. An equally controversial bearing is perceptible in the remainder of their philosophy. Their greatest enemies, the Epicureans, had adopted the *mechanico-corpuscular* theory of Democritus, which accounted for all physical phenomena by the varieties in size and figure of the ultimate atoms of which all substances are the aggregate. The fortuitous concretions which thus became the first cause of all things, had attracted the partialities and won the assent of a sect averse in all things equally to limitation or constraint. The Stoics espoused the opposite doctrine of a one all-pervading substance, a permeating ether, a creative fire, the source of life and law to the material

universe. On this they built their doctrine of a universal providence, excluding chance in the least things as in the greatest, and directing all events by irresistible necessity to the promotion of perfect good. The same hypothesis furnished them with a ground for the first principle of their ethical doctrines. 'Live according to nature' is, with the Stoics, the expression of the coincidence which ought to exist between the human will and the universal reason, which, as we have seen, they identified with the life and power of nature. This coincidence is virtue, the only good; as vice, its opposite, is the only evil. All things else are in themselves indifferent; being approved or disapproved only by comparison. Virtue is the perfect harmony of the soul with itself; vice is, in its essence, inconsistent and self-contradictory. The wise man, the ideal of human perfection, is absolutely, and without qualification, free. His actions are determined by his free will with a power as irresistible as that by which universal nature is guided and animated. In the one no less than in the other, freedom and necessity are one.

In these doctrines the controversial character to which we have adverted is sufficiently obvious. Much, however, that is exaggerated and paradoxical, both in the tenets of the Stoics and in those of their opponent Epicurus, is to be accounted for by a reference to the political circumstances of the age in which both lived.

In the declining period of the Roman republic, as well as in the darkest periods of the empire, we find the noblest Romans seeking for consolation in the doctrines of one or the other of these rival sects. Brutus, Seneca, Epictetus, and the philosophic emperor Aurelius, are among the names of the most celebrated Roman Stoics. Little, however, was done by the Romans to advance the speculative part of the stoical philosophy, which was indebted for its systematic form to Cleanthes and Chrysippus.

The chief sources of information concerning the doctrine of the earlier Stoics are the philosophical works of Cicero; for their logic, the *Academic Questions*; for their ethics, the treatise *De Finibus*, and the *Tusculan Questions*; and for their theology and physics, the books *De Natura Deorum* and *De Fato*. See also *Diog. Laert.* 1. vii. Plutarch, *Adv. Stoicos*, &c.; Ritter, *Hist. of Ancient Philos.* xi. part v.

Stoker. The labourer employed to replenish a furnace with coals.

Stoking. The operation of replenishing a furnace with coal, and of keeping it in proper order, by clearing away the ashes and clinkers, so as to maintain a vigorous combustion. Much skill is needed to stoke the furnace of a steam boiler successfully; and one stoker will often be able to keep the steam well up when another of equal strength and diligence will fail altogether. One main indication to be fulfilled is to spread the coal evenly over the bars of the grate, and to leave no holes or open places in the fire, through which the cold air will rush, and diminish the temperature of the furnace. In long furnaces, it is necessary to be careful to throw the coals well back against the bridge, so as to keep that part of the grate covered; and it will often be found that more steam will be generated if the furnace bars are shortened should their length exceed six feet. The large lumps of coal should be broken up with a hammer into pieces of the size of a hen's egg. In locomotives the coal should be fed a little at a time, and it will often be advisable to shut off the feed water temporarily in ascending inclines.

Stola (Lat.; Gr. στολή). A dress of which the name was borrowed by the Romans from Greece, but acquired in their language a peculiar signification; being the habit appropriated to women. It was a long vest, coming down to the ankles; was worn within doors, and covered by the palla or cloak when they went out; as described by Horace, *Sat.* I. ii. 99:—

Ad talos stola demissa et circumdata pallâ.

Common prostitutes, at least in the age of Horace, were not permitted to wear this distinguishing garb of the Roman lady.

The stole, as an ecclesiastical ornament, is a long narrow band, or scarf, with fringed ends, worn in the Roman and other churches by deacons over the left shoulder, and by priests crossed over the breast to the girdle, and thence descending in front on both sides down to the knees. [VESTMENTS.]

Stole, Groom of the. An officer of the royal household in the lord chamberlain's department. He is first lord of the bedchamber; his title is derived from the long robe (stola) worn by the sovereign on solemn occasions.

Stolon (Lat. stolo, *a shoot*). In Botany and Horticulture, a sucker or young shoot produced from the root or crown, which takes fresh root at intervals, and thus forms independent plants.

Stolzite. A name given to Tungstate of lead, after Dr. Stolz. [SCHEELETINE.]

Stomacace (Gr. στομακάκη). A fetor of breath, arising from ulcerated gums. Mouthwashes, with tincture of myrrh and borax, and the internal use of tonics, are the remedies which relieve it.

Stomach (Gr. στόμαχος, strictly *a mouth*, hence *the throat*: in later Greek medical writers, the word is used in the modern sense of the term). The human stomach is a somewhat oblong and rounded membranous bag, situated in the epigastric region. It is largest on the left side (or *cardiac* end), and gradually diminishes towards the right or lower orifice, which is called the *pylorus*. Like the intestines, the stomach has three coats or membranes, connected together by cellular membrane. The exterior or peritonæal coat is a dense firm membrane; the internal or villous coat is

soft, mucous, and vascular; the central coat is muscular, and the glands of the stomach are situated between it and the villous coat. The stomach is largely supplied with nerves, which come from the eighth pair and sympathetic. They are derived chiefly from the cœliac or solar plexus, and are accompanied by veins which empty themselves into the vena portæ. The lymphatics of the stomach proceed directly to the thoracic duct. [ANATOMY; DIGESTION.]

Stomach Pump. A small pump or syringe with two apertures, the valves of which are so arranged as to admit of liquids being drawn out of or injected into the stomach, by means of a flexible tube.

Stomapods (Gr. *στόμα, a mouth*, and *πούς, a foot*). The name of an order of the *Crustacea*, comprehending those in which the maxillary feet are formed like the first four thoracic feet.

Stomata (Gr.). In Botany, the term applied to certain passages through the epidermis of plants, having the appearance of areolæ, in the centre of each of which is a slit that opens or closes, according to circumstances, and lies over a cavity in the subjacent tissue. They are universally regarded as spiracles or breathing pores.

Stone, Artificial. Many kinds of material have been employed in the manufacture of artificial stone. The kinds most in use are some modification of *Roman cement*, hardening rapidly and in damp air; *Portland cement* is still better, but of the same nature; *terra cotta*, a kind of brick that requires burning; and *silicious stone*, a composition consisting of sand and other material made into a paste by an aqueous solution of silicate of soda, the water being driven off in a kiln and the material cemented by a kind of glass.

A new material, called *concrete stone*, has recently been introduced, which seems likely to supersede all these for many purposes. Any stony materials, however incongruous, are made into a paste with fluid silicate of soda, and then by mere exposure to a solution of chloride of calcium, double decomposition is induced, the silicic acid combining with the calcium to form silicate of lime, a cementing medium firmly attaching all the particles, and the chlorine combining with the soda to make common salt, which is readily washed away.

The great objection to most of the older varieties of artificial stone having a clay basis is that they will not long endure the action of weather, are apt to crack, and also to become covered with green vegetation. Stones also that pass through the kiln almost invariably lose their proportions and become distorted; this, however, is more especially the case with the clays, and the concrete stone is free from it.

Stone in the Bladder. [CALCULUS; URINE.]

Stone Blue. A compound, the basis of which is usually an impure starch, or mixture of starch and gluten, being the starchmakers' refuse, coloured either by indigo or Prussian blue. It is used in the laundry to cover the yellow tint of linen.

Stone Borers, called also **Lithophagi.** Molluscous Bivalves, which, by means of a fleshy foot, on which they turn as on a pivot, perforate or bore into rocks.

Stone Coal. A common name for ANTHRACITE.

Stone Curlew. The name of a large species of plover, the *Œdicnemus crepitans* of Temminck. It appears in England at the latter end of April; frequents open hilly situations; makes no nest, but lays two eggs on the bare ground; and emigrates in small flocks about the end of September.

Stone Galls. A technical term applied to nodules of clay occurring in sandstone; they often fall out on exposure to weather, and render the stone unfit for architectural purposes.

Stone, Natural. Stones are of many kinds and used for many purposes. They are chiefly referable to the following varieties: LIMESTONE, SANDSTONE, MARBLE, and GRANITE. Fissile stones are called SLATES, SLABS, or FLAGS. Building stones, capable of being worked readily by the tool, are called *free stones*. Stones used for road-making are called ROAD METAL.

The selection of a stone for any required purpose is a matter involving much knowledge and experience. Reference should be had to the nature of the exposure, the part of a building, whether foundation or superstructure, and the style of the building, as stones that will stand one kind of exposure fail in another place, and those that are sound when placed square, so as to expose only a vertical section, will not always last if much sculptured. It is well known that many stones, perfectly durable in the neighbourhood where they are found, may not last if removed to buildings in large towns at a distance.

Stones are subject to injury when placed in buildings, in various ways. 1. Being removed from the quarry, where they contain much water, they are exposed to irregular drying, and consequent cracking and peeling. Hence the importance of attending to the planes of stratification. 2. When absorbent, as they are very unequally exposed to the rain in the different parts of a building, they must be selected with this end in view. 3. They are exposed to the acid vapours present in the air. Should the stone not be placed in the building in its natural position, it will be more subject to peeling than if so placed. Should it be absorbent and not previously weathered, it will be very apt to rot; and under any circumstances, if a limestone or with a calcareous cement, it will be chemically acted on. [BUILDING MATERIALS.]

Stone Ochre. A yellow pigment resembling Roman and Oxford ochre. Stone ochres are found in balls and globular masses of various sizes in solid stone, or lying near the

surface of rocks, in the Carboniferous Limestone quarries of Gloucestershire and elsewhere. [LIMONITE.]

Stone, Preservation of. The subject of the preservation of stone has long attracted attention, but as yet with no thoroughly satisfactory results. The most usual application consists of some variety of paint, but this requires repeating from time to time. The method most likely to be effectual is some modification of a process introduced some years ago, first in Germany, and then in England. This method involves the deposit on the surface, and within the substance of porous stones, of a thin glaze, indestructible, and penetrating more or less according to the degree of porosity.

It is a remarkable but well-ascertained fact, that the same preparation which appears satisfactory, even on a large scale, on some kinds of stone in certain localities, cannot be depended on either for the same stone in other localities, or for other stones in the same exposure. Thus, no one treatment has been found to succeed generally. It is also very difficult, if not impossible, to decide beforehand with any certainty which of a number of stones will be likely to resist exposure, and which will decay, under given circumstances. This, however, is easier than to restore stones, or to stop the decay when they have become seriously injured by exposure.

Almost all stones will resist exposure better if hardened and weathered for some time before being used. If, also, they can be preserved till lichens grow upon them, they are still more likely to resist the action of acid vapours. Stones that have once thoroughly decayed from the surface hardly admit of any treatment.

Stone Salt. [ROCK SALT.]

Stonechat. A species of warbler, forming the type of the genus *Saxicola* of Bechstein, so called because its chatter was supposed to resemble the knocking of stones together. It is the *Sylvia rubicola* of Latham; *Motacilla rubicola* of Linnæus. Also called the *chick stone*.

Stonecrop. The common name for *Sedum acre*, and also used as a popular name for the genus *Sedum*.

Stonesfield Slate. Two beds of calcareous flagstone or tile, sufficiently fissile to be available for roofing purposes, are worked under this name near the village of Stonesfield in Oxfordshire. They are represented by somewhat similar beds at Colley Weston, near Stamford in Northamptonshire, and they occupy a definite geological position at the bottom of the upper division of the lower oolites, between the Great Oolite and Fuller's earth. They are chiefly interesting as containing the most distinct remains of mammalian quadrupeds that have yet been found in beds older than the Tertiaries. These animals are small. The lower jaws of several individuals have been found, and they are referable to different genera, some marsupial. Many other remarkable fossils have been found, proving the near vicinity of land at this period in England.

Stooking. The Scotch term for setting up sheaves of corn in stooks, i.e. shocks. The operation is performed soon after the corn is cut; it being previously tied into bunches or sheaves.

Stool (A.-Sax. stol, Ger. stuhl). In Horticulture and Arboriculture, a stemless mother-plant used for propagation by annually bending its branches into the soil; the branches so bent down forming layers, and the process being designated *laying* or *layering*. Also the root or stump of a timber tree, which throws up shoots. Coppice wood consists chiefly of the shoots sent up by the roots or stools of trees or shrubs which have been cut over by the surface. In general, all Dicotyledonous trees are endowed by nature with the property of sending up shoots from the stumps or stools; but this is not in general the case with the Gymnosperms or Coniferous trees, and hence a wood of pines or firs, when once cut down, can never be renewed, except by seeds.

Stools. Small channels outside a ship to receive the dead-eyes of the backstays.

Stop Order. In Law, an order which may be obtained by any person interested in a fund in the Court of Chancery, for the purpose of preventing the fund from being transferred or paid out without his knowledge.

Stop Valves. Valves introduced between boilers where several are employed to drive an engine, to the end that any boiler may, when desired, be thrown out of use without impairing the efficiency of the rest, which is done by shutting the stop valve in the steam pipe which connects it with the other boilers of the system.

Stoppage in Transitu. In Mercantile Law, the right which an unpaid vendor of goods has, in the event of the insolvency of the purchaser, to stop the goods while they are on their way to the consignee, and before the termination of their journey.

Stopper. On Shipboard, an apparatus for applying the brake to the capstan when the cable is running out. *Stoppers* are also obstacles placed firmly at a given point in the cable to prevent it from running beyond that point through the hawse-hole.

Stoppering a Fall. Making fast the fall of a tackle to some fixed object, at a point intermediate between the running and standing ends. [TACKLE.]

Stopping-up Pieces. Timbers used to afford lateral support in launching a vessel.

Storax (Lat.; Gr. στύραξ). A fragrant balsamic exudation from the *Liquidambar styraciflua* It is generally much adulterated.

Stork (A.-Sax. storc). An English name, equivalent to the *Ciconia* of modern ornithologists. The white stork (*Ciconia alba*) visits England, though rarely.

Storm (Ger. sturm; connected with the verb *stir*). The causes of those violent commotions of the atmosphere to which we give the names of *storms, tempests, hurricanes, tornadoes*, &c. are involved in great obscurity, chiefly from the difficulty of obtaining a pre-

cise knowledge of the various circumstances with which they are accompanied. In order to ascertain the general laws of these phenomena, it would be necessary to determine, in a great number of particular instances, the place and time at which the storm begins and ends, the path described by it, the extent of atmosphere disturbed, the direction and force of the wind, and the barometric pressure at every part of the disturbed column during the whole time of its continuance. But several of these points could be determined only from the comparison of a great number of simultaneous observations on that tract of the earth's surface over which the storm passes; while, from the nature of the thing to be observed, it is evident that a few insulated observations can at best be expected in almost any case. Besides, a storm for the most part passes over some part of the sea, where, unless a ship unfortunately happens to be caught in it, no observation can be made, and no evidence can be obtained of its existence.

It is in the torrid zone that storms display the greatest violence, and rage with most destructive fury. In more northern latitudes they are comparatively rare, and in the polar regions they seldom amount to more than a strong wind. These facts seem to show that there is some connection between violent atmospheric movements and the velocity of the earth's surface, due to axial rotation in different latitudes.

Until recently, it was generally believed that during a hurricane the wind at every part of the agitated mass blows in a rectilinear and parallel direction, and a storm was considered to be sufficiently explained when it was described as a wind blowing with a velocity of 100 or 120 miles in an hour. A comparison of the recorded accounts of the circumstances attending several storms has of late years shown that this idea was erroneous, and that the phenomena are considerably more complicated.

Franklin appears to have been the first who remarked that storms travel in a direction opposite to the actual movement of the wind at the time when the storm is raging; and he ascribed the phenomenon to a great but partial rarefaction of the air, arising from the sudden precipitation of vapours, or other causes, the consequence of which would necessarily be a simultaneous rush from all quarters to fill up the vacuity; and the mass of air being thus set in motion by a sort of aspiration, the gale will be first felt at those places towards which it blows. (*Letters and Papers on Philosophical Subjects.*) In a work on winds and monsoons, published in 1801, Colonel Capper was led, from a comparison of the details respecting the hurricanes at Pondicherry and Madras in 1760 and 1773, to remark that these hurricanes must have been whirlwinds, whose diameter could not exceed 120 miles, and that the velocity of the wind at any point was due to the rotatory velocity of the vortex. He also supposed that, besides the gyratory movement which forms the characteristic of the whirlwind, a storm has probably also progressive motion. Colonel Capper's speculations, however, appear to have met with little attention until the subject was taken up by Mr. Redfield, of New York, who, in a series of papers published in the American journals, diligently collected and examined a great number of observations relative to the storms of the West Indies and North American coasts, and arrived at similar conclusions. The following general phenomena appear to be established: 1. The severest hurricanes originate in tropical latitudes to the north or east of the West Indian Islands. 2. They cover simultaneously an extent of surface from 100 to 150 miles in diameter, acting with diminished violence towards the exterior, and increased energy towards the interior of that space. 3. The tract over which the hurricane passes is not a straight line. South of the parallel of 30° north latitude, it proceeds in a westerly course inclined to the north; but when it comes to about this parallel, it changes rather abruptly to the north and east, and continues to incline gradually more to the east. The average progressive velocity appears to be from fifteen to twenty-five miles per hour. 4. The duration of a storm at any particular place depends, of course, on the extent of the mass of agitated air, and the progressive velocity; and storms of smaller extent move with even greater rapidity than large ones. 5. The direction of the wind in a hurricane is not in the direction of its progress. When the progressive motion of the storm is westward, the wind at the commencement is from a northern quarter, and during the latter part of the gale from a southern quarter of the horizon. When the progressive motion is eastward, the phenomena are reversed; the wind blows at first from a southern quarter, and towards the end of the gale from a northern quarter of the horizon.

From these phenomena, and particularly from the last, Mr. Redfield concludes that the great body of the storm whirls in a horizontal circuit round a vertical or somewhat inclined axis of rotation, which is carried forward with the storm; and that to a spectator placed at the centre the direction of the rotation is invariably from *right to left*. It is to be understood, however, that the phenomena now described, and the conclusions drawn from them, apply only to the northern hemisphere.

Another fact deserving of attention is, that the barometer, in all latitudes, sinks during the first half of the storm in every part of its track, and rises during the second. This phenomenon is ascribed to the effects of the centrifugal force of rotation; and such is the regularity of its occurrence, that it has been considered as affording of itself a strong proof of the rotatory character of the motion.

Colonel Reid, of the engineers, having been officially employed to restore the government

buildings at Barbadoes, blown down by the great hurricane of 1831, was led to investigate the subject generally; and in his work, entitled *An Attempt to Develope the Laws of Storms, &c.*, he has collected and given the results of an immense number of details, obtained from an examination of ships' logs furnished to him by the Admiralty, and from other sources. These results he considers as confirming in all respects the conclusions of Mr. Redfield respecting the gyratory motion of the gale from right to left; its progressive motion in a curve line, first westward, and then towards the north and east; the position of the vertex of the curve at or near the 30th degree of latitude; and the fall of the barometer during the first half of the storm, and its rise during the second. Colonel Reid has also given an account of several great hurricanes in the southern hemisphere, from which it appears that the southern storms follow exactly the same laws as the northern, but in a reversed order. The direction of the rotation is from *left to right*; the centre of the gyrating mass advances first eastwards, then turns towards the south, and falls off towards the south-west and west, the vertex of the curve being at the 30th degree of south latitude. In the northern hemisphere, the West Indies and Atlantic coast of North America appear to be the places where storms most frequently rage; in the southern, the focus of storms appears to be placed near the Mauritius.

The uniformity of the direction of the rotatory motion of the hurricane, and its opposite direction in the opposite hemispheres, was explained by Mr. Redfield from theoretical considerations respecting the origin of storms, which he supposes to be produced by the mingling and collision of two atmospherical currents near the outer border of the trade winds; namely, the superior or equatorial stream, and the polar stream, which constitutes the *trades*. On looking at the curves representing the paths of the hurricanes on the charts projected by Mr. Redfield and Colonel Reid, it is difficult to avoid the conclusion that the direction of their progressive motion is mainly determined by the configuration of the continent. Whilst hurricanes are gyrating masses of air with a vertical axis, *squalls* appear to be caused by similar gyratory movements, in which, however, the axis is horizontal.

Although the subject of storms has received much elucidation from the labours of Dove and others, aided by the resources of the electric telegraph, still much further investigation will be required before the phenomenon is fully understood. Independently of the interest which attaches to the subject in a meteorological point of view, a knowledge of the general laws which regulate the phenomena of storms would be of immense importance, inasmuch as it would enable the navigator to avoid those tracts of the ocean in which they prevail at particular seasons, or at least, if surprised by a storm, to steer on the course by which he may soonest escape from it or fall into its wake. Even the knowledge at present possessed, imperfect as it is, has been employed by the late Admiral Fitzroy with a certain amount of success in the prediction of most of the storms which have recently visited these islands; and the exhibition of his storm signals at our principal ports has been the means of preserving many lives and much property. (See, in addition to the works already cited, *Silliman's Journal* from 1831; Prof. Forbes' 'Reports on Meteorology,' in the *Reports of the British Association* for 1832 and 1840; and the *Edinburgh Review*, vol. lxviii.) [Winds.]

Storms, Law of. [Storm; Winds.]

Storthing. The parliament of Norway. It is elected once in three years, and sits every year for the despatch of business. The election is double. Every qualified person (an owner or life-renter of land paying taxes in the country, and everyone possessing land or houses of 150 rix dollars value in towns) has a vote for the election of councillors, who elect out of their own body the representatives of the country. These must be from 75 to 100 in number. The storthing, when elected, divides itself into two houses; one-fourth, chosen by the rest, joining the *lagthing*, or upper house, which also forms a court before which the ministers may be impeached; the remainder the *odelsthing*, or lower house. The storthing has the usual powers of a legislative assembly in a constitutional country, and the king has only a suspensive veto; which, if the storthing passes a law three times in six successive years, becomes of no effect. This was exemplified by the law for the abolition of hereditary nobility, passed in 1821.

Stove (Ger. stube, *a room* or *chamber*: in old Saxon stov, stowa, is any dwelling or enclosed place; the Frisian stev, the Icelandic sto, and the Swedish stö, have the same meaning). A receptacle for the combustion of fuel for the purpose of heating houses, &c. The common fire-grate for the combustion of coal, with its various appendages, is generally called a *stove*; hence *register stoves, Bath stoves*, &c. These are often, and indeed generally, very unscientifically constructed, and calculated to consume a large quantity of fuel, with a proportionate waste of heat. They are generally intended to diffuse warmth principally or entirely by *radiation*, and should be placed as near the ground as possible; while the different parts into the contact of which the burning fuel is brought should be of fire-brick, or some similar composition, which is a bad conductor but a good radiator of heat. It is manifest that in our common fire-places the enormous volume of hot air which passes up the chimney is not available as a source of heat; hence, in colder climates, and where greater economy of fuel is studied, the fireplace is frequently closed in, and contained in an iron box which projects into the room, while the heated air before it

finally enters the chimney is made to circulate through tubes or pipes, to which it communicates much of its excess of heat, and these again impart it to the surrounding air. What are termed *German stoves* are usually made upon such principles; and in them the fuel is often introduced, and the air required for the support of its combustion admitted, on the outside of the room in which the stove with its flues and heating surfaces is placed.

In *Arnott's stoves* the heat is similarly but more scientifically economised. Only enough air is admitted to keep up the slow combustion of the fuel, and the heat is communicated to the radiating surfaces of the stove; so that before the air which has passed through the fuel finally enters the chimney it has been deprived of the greater part of its available heat. These stoves are also so constructed as, by means of thermometric or self-acting registers, to adjust with much nicety the supply of air, so that neither more nor less may enter than is required to maintain the combustion of a given quantity of fuel.

In *Fcetham's air-stoves* the common open fire is retained; but the heat is to a certain extent economised by causing the hot air before it enters the chimney to communicate a portion of its heat to an iron box, over which a current of air passes and is sent warm into the room.

It is manifest that our common open fires must act as powerful ventilators, and that the large quantity of air which is driven up the chimney must be supplied in some way or other through the apartment in which the fire is burning. This supply of air is generally left to chance, and finds its way into the room by crevices in the doorways and window sashes, or between the boards of the floor, or any similar accidental passage through which it can make its way; and as, in London at least, the air always abounds in fuliginous particles, these are carried in along with it, and show its track by the blacks which it deposits. If this supply of air is inadequate, and it generally is so in new and well-built houses, in consequence of the tightness of the doors, windows, and floors, the chimney of necessity smokes, and the door or window requires to be left open to prevent such an effect. This evil may usually be effectually prevented by admitting fresh air from without through some proper and adequate channel, and various ornamental or concealed apertures may be contrived for the purpose; in the best arrangement of which, however, much practical as well as theoretical skill is often essential.

When rooms are warmed by German or Arnott's stoves, the ventilating powers of which are very inferior to the open grate, *ventilation* requires to be strictly attended to. Where buildings are warmed by currents of hot air sent up from stoves on the basement story, great attention should also be paid to ventilation; and in such cases the leading object should be to send in a large volume of air very moderately heated (to about 100°), rather than a small quantity of very hot air: the latter does not readily mix with the surrounding cold air, but forms a distinct and rapidly ascending column, which does not diffuse itself where most wanted; and it is apt to have a disagreeable and burnt odour, arising from the charring of the particles of organic dust which are carried with the air over the too highly heated surfaces of the stove or flues. A little aqueous vapour, sent in along with the warm air by placing a saucer of water in some convenient situation, is often effectual in preventing the disagreeable sensations occasioned by respiring too dry an atmosphere.

STOVE. In Horticulture, a structure in which tropical plants, requiring a considerably higher temperature than that of the open air in Britain and similar climates, are cultivated. Stoves are adapted for various purposes; but the principal are the *dry stove* and the *damp stove*. The dry stove is a structure the atmosphere of which is heated to the temperature of from 55° to 60° during winter, and in which the plants chiefly cultivated are succulents, such as species of *Cereus*, *Stapelia*, *Euphorbia*, and others having a similar habit. During winter these plants require very little water, and during summer they require intense heat, with abundance of air and water during fine weather. Dry-stove plants are less cultivated than formerly. The damp stove, sometimes also called the *bark stove*, requires a temperature of between 60° and 70° during winter, with a proportionate increase during summer; accompanied, in both seasons, with a high degree of atmospherical moisture. This moisture is produced partly by evaporation from the bark bed in which the plants are plunged, but chiefly by watering the floor of the house, and by syringing the walls and plants. During summer the plants grown in the bark stove require all the light which the atmosphere in this country is capable of producing, though in many cases they require screening from very bright sunshine; they also need a free daily admission of fresh air, as in the dry stove. Both are heated by means of smoke flues, or of hot water or steam, circulated in cast-iron pipes, or in brick or wooden tanks or troughs.

The plants cultivated in the moist stove are exclusively those of the tropics; and those which require the highest degree of heat are chiefly Monocotyledonous plants, such as the ginger, the plantain, the banana, the sugar cane, palms, *Orchidaceæ*, &c.; and such Dicotyledonous plants as the bread fruit, the yam, the mangosteen, and other East Indian plants. The bark bed, or its substitute, the hot-water tank, is employed chiefly for insuring a uniform degree of moisture and heat to the roots, and also as a reservoir of heat to supply the atmosphere of the house in case of any diminution from the flues, water or steam pipes, or the sun. Stoves of every description require a constant degree of attention from the gardener throughout the year, more especially such as are devoted to the palms, the bananas, the pine

apple, the vine, and the *Orchidaceæ*, as well as those employed generally for the forcing of early vegetables and fruits.

Strabismus (Gr. στραβισμός, *a squinting*, from στραβός, *distorted*). An unnatural obliquity in the axis of the eye, arising from various causes. It may often be, to a great extent, overcome, especially in children, by blindfolding the sound eye, presuming one only to be affected. In very bad cases, especially those of squinting inward (and such are by far the most common), an operation which has lately been introduced is often effectual in greatly relieving the deformity; it consists in dividing the internal rectus muscle of the eyeball, which is done by a proper scissors without externally wounding the eyelid.

Straight Arch. In Architecture, the arch over an aperture, whose intrados is straight, but with its joints drawn concentrically, as in a common arch.

Straight Joint Floor. In Architecture. [FLOOR.]

Straining Piece. In Architecture, a piece of timber, designed to prevent the nearer approach of two pieces of timber in a piece of framing. The collar of a queen-post roof may be cited as an illustration of the meaning of a straining piece.

Strains on Guns. [RIFLED GUNS.]

Strait (Fr. étroit, Ital. stretto, Lat. strictus, *drawn together*, *tight*). In Geography, this term signifies a narrow pass or frith separating one country from another.

Strake. In wooden Shipbuilding, the term for a line of planking extending from the stem to the stern. The *garboard strakes* are on the outside, next the keel; the *limber strakes* are within, adjoining the limbers; the *thick strakes* are within also, at different heights between decks; the *sheer strakes* and *black strakes* are on the straight part of the outer sides.

Strakonitzite. A yellowish-green mineral resembling Steatite, found in pseudomorphous crystals at Mutenitz, near Strakonitz, in Bohemia.

Stramony or **Thorn Apple.** The *Datura Stramonium*, an indigenous narcotic plant, the seeds and leaves of which are used in medicine. The dried leaves are occasionally smoked, like tobacco, for the relief of spasmodic asthma; and an extract of the seeds is used as a sedative in some painful chronic affections. [DATURA.]

Stranger (Fr. étranger, from Lat. extraneus, *foreign*). In the Old Testament, the denomination of persons of foreign, i.e. not Israelitish, extraction, resident within the limits of the promised land, and entitled, through conformity to the law, to keep the passover and enjoy the rest of the Sabbath. They were treated with great liberality; but whether allowed to hold land or not, is doubted.

Strangury (Gr. στραγγουρία). A difficulty in voiding urine.

Strap. In a capstan on board ship, an iron bar of great strength forming part of the brake apparatus.

Strata. [STRATUM.]

Strategical Line. In the Art of War, that line which affords better means of communication than all other intermediary lines between two *strategical points*.

Strategical Point. In War, every point on the theatre of war, whatever be its nature, which conduces in any manner to strengthen the line of operation or of communication. *Decisive strategical points* are those only which are decisive in insuring the success of any operations of strategy either for offence or defence. Thus any point may, by the relative situations of the hostile armies, become a decisive strategical point; but the points most likely to do so are strong positions commanding the principal great roads or a permanent bridge over a great river, or blocking up the approach to passes over a range of mountains.

Strategy (Gr. στρατηγία, from στρατός, *an army*, and ἄγω, *I lead*). The science by which a general is enabled to trace the plan of a campaign, determining the positions of which it is necessary to be master, and fixing the direction in which the communications should be established. Strategy has also been defined as the art of placing in a certain position at a certain time a body of troops in fighting order superior to that body which your enemy can then oppose to you. Strategy relates to the movements of an army on the theatre of war, where not in actual contact with an enemy, and merges into *tactics* on the field of battle. [TACTICS; WAR.]

Strath (Gael.; Welsh ystrad). In Scotland, this word is generally understood to signify a valley of considerable size, whose appellation is determined by some river running through it, or some particular characteristic.

Stratification. The arrangement of the various materials of which the earth's crust is composed in *strata*, *beds*, or *layers*, reposing one on another with more or less appearance of regularity, is called, in geological language, *stratification*, and rocks are said to be *stratified* or *unstratified*, to have *conformable* or *unconformable stratification*, accordingly as they present evidences of mechanical or chemical origin, and as they seem to have succeeded each other without or after disturbances altering the horizontality of strata previously placed.

We say, then, that the crust of the earth is *stratified*, when it consists chiefly of distinct strata or layers of different materials. These differ in depth and extent; but (what is most essential to our present purpose) they follow each other, on the large scale and as masses, in an apparently regular and uniform succession in all places, districts, and countries where they admit of examination and have been attentively studied. They appear, in most instances, to rest upon, and are blended with, invaded, and in some few instances overflowed as it were, by substances which are *not* distinctly stratified, and which most geologists have agreed in calling *unstratified rocks*. The former, or the stratified rocks, from their texture and con-

tents have apparently been formed under water; and many of them abound in fossil remains. The *unstratified* rocks, on the other hand, are in some few instances of volcanic origin; but most of them, from their position, texture, and effects upon their neighbours, are METAMORPHIC. *Water*, on the one hand, and chemical action on the other, seem to have been the great agents to which the present aspects of the earth's surface are referable. [CONFORMABLE; UNCONFORMABLE.]

Stratopeite. A mineral found at Pajsberg's iron mine in Sweden. It is, probably, an altered form of Manganese Spar.

Stratum (Lat.). A *stratum* in Geology is a single bed or layer of rock as it lies in the earth. Several such layers together form a group of *strata*, and if compacted and in any way distinguishable from other similar groups, a group of strata forms a *stratified rock*. [STRATIFICATION.]

Stratus. [CLOUD.]

Strawberry. The well-known grateful fruit of the plants of the genus *Fragaria*. Strawberries contain a very small quantity of nutritive matter. The grains or seed-like pericarps are not digestible, and sometimes excite intestinal irritation; so that some physicians have directed their patients to suck strawberries through muslin. [FRAGARIA.]

Streak (A.-Sax. stric). The appearance which arises from scratching a mineral with the point of a knife. The streak is *similar* when the colour of the scratch is the same as that of the mineral, but *dissimilar* when the colour varies.

Stream Tin. Native oxide of tin or Tin-stone, found in rounded particles and masses, mixed with other alluvial matters, in the beds of streams, whence it is obtained by washing. Very little of this ore is now procured from Cornwall, but large quantities of poor quality are exported from the islands of Banca and Billeton in the Malay Archipelago.

Stream Works. Operations intermediate in their nature between mining and quarrying, carried on where there are natural streams of water and gravel in the neighbourhood containing native metal or heavy ore. Gold and tin ore are the substances usually obtained in this way, although lead ore is sometimes also got, and copper ore in one or two cases. The operation of separating the ore from the sands and gravel is simply mechanical, and consists in allowing a current of water to pass over the mixed heap and accumulate the various contents into heaps according to their specific gravity.

Some of the more elaborate contrivances for streaming are ingenious and well adapted for the purpose, but generally the simplest are the most efficacious. Catch pits to receive the mud and slime, and contrivances to regulate the rate of motion of the water, are the chief objects in view.

Strelitz (Russ., plur. strelitzy, said to be derived from strelai; Ital. strale, *an arrow*). A soldier of the ancient Muscovite militia was so called. The strelitzy were the only standing army of the empire; and, like the Turkish janissaries, constantly interfered with its government. Their last revolt was in 1698, during the absence of the Czar Peter I., who, on his return, cashiered the corps altogether.

Strelitzia (after Charlotte of Mecklenburg Strelitz, queen of George III.). A gorgeous-flowered genus of *Musaceæ*, consisting of large herbaceous plants, natives of the Cape of Good Hope. Their foliage consists of long stalked leaves sheathing at the base, arising from a contracted stem, the flower-stalk encircled below by the sheath of the leaf-stalk; while its upper portion gives origin to a large bract or spathe placed obliquely, within which are the flowers. The perianth consists of six segments, in two rows; the three outer ovate lance-shaped, nearly equal, usually of a bright orange colour; the three inner unequal in size; the two front ones bright purple, united together, each one lobed on the outer side, so that the two united petals are distinctly halbert-shaped. The seeds of *S. reginæ* are eaten by the Kaffirs. The fine leaves and large orange and purple flowers render this one of the most splendid of plants. *S. juncea* is remarkable for the usual absence of a blade to the leaf, so that the leafstalks resemble monster rushes.

Strength of Materials. The force with which a solid body resists an effort to separate its particles or destroy their aggregation. [SOLID BODIES, FLOW OF.] There are four different ways in which the strength of a solid body may be overcome: by tension, by compression, by bending, and by twisting. But all these strains may be resolved into strains of extension and compression, which therefore it will be sufficient here to consider. An accurate appreciation of the nature of strains and a sound knowledge of the strength of materials constitute the main part of engineering science; and it is most important, therefore, to every engineering student that these topics should be clearly and accurately apprehended.

In investigating the strength of materials there are three fixed points, varying in each material, of which it is necessary to take note: the ultimate or breaking strength, the elastic or proof strength, and the safe or working strength. Almost every kind of material will be broken in time by an amount of strain that would not suffice to break it at once; and it is necessary, therefore, to give a large margin of strength to all engineering structures, to insure safety. The tensile and crushing strengths of most materials are very different. Thus the ultimate tensile strength of good ordinary wrought iron is about 60,000 lbs. per square inch of section, or over twenty-two tons, while its crushing strength is usually taken in this country at about 16 tons. Of cast iron the average tensile strength is a little over 7 tons per square inch of section, and the crushing strength is over 40 tons per square inch of section. Mr. Hodgkinson found by his ex-

periments that the ultimate resistance of cast iron to crushing varies from 38 to 68 tons per square inch of section, and that 49 tons might be taken as the fair average resistance of good iron. Experiments on the crushing strength of short pieces of wrought iron give a result as high as 29 tons per square inch of section, and Rondelet gives the crushing strength as 35 tons, Weisbach as 25 tons, Claudel as 25 tons, Vose as 21 tons, and Ritter as 19 tons per square inch of section. But the result of experiments on the crushing strengths of cells and tubes does not warrant the adoption of a larger crushing strength than 16 to 18 tons per square inch of section in the case of thick tubes, whereas in the case of thin tubes the crushing strength per square inch is very much less. [TUBULAR BRIDGE.] Steel and homogeneous iron are of about twice the strength of common wrought iron. It was found on testing bars of Howell's homogeneous iron in Mr. Kirkcaldy's testing machine, in 1866, that a bar of this iron required 44·6 tons to tear it asunder, and that it bore a strain of 26 tons without its elastic limit being exceeded; the bar, though stretched like a very stiff spiral spring by this strain, returning to its original length when the strain was removed. The advantage of employing such a material in bridges and other structures of great span is very great, since the greatest part of the load of such structures is to bear their own weight, and if the weight be made one-half less, the strength will necessarily be greatly increased. A bar of homogeneous iron $3\frac{1}{4}$ miles long may be hung up at one end without its working strain being exceeded; or a bar $5\frac{1}{2}$ miles long may be similarly hung up without its breaking strain being exceeded. A telegraphic wire formed of this metal may be carried over a span of 3 miles with a deflection of only one-eighth of the span without its elastic strength of 26 tons per square inch of section being exceeded. Ordinary wrought iron is stretched from $\frac{1}{[illegible]}$ to $\frac{1}{13000}$ of its length for every ton of direct tensile strain per square inch to which it is exposed. Homogeneous metal and steel are stretched only about one-half of this, or about $\frac{1}{16500}$ of their length per square inch of section for every ton of tensile strain. The crushing strength of tubes of homogeneous iron and of cruciform pillars of steel was also tested at Mr. Kirkcaldy's experimenting works in 1866. A tube of homogeneous metal $1\frac{7}{8}$ inch external diameter, $\frac{3}{8}$ of an inch thick, and 4 feet long, bore a strain of 17 tons 3 cwt. per square inch of section, when a slight lateral deflection was observed; and on increasing the strain to 21 tons per square inch of section, the tube yielded laterally and flew out of the machine, though it still remained sound and free from flaw. Four angle irons of steel, $3\frac{1}{2} \times 3\frac{1}{2} \times \frac{5}{16}$ thick, were then riveted together into a cruciform pillar 4 feet long and presenting a cross section of 8 square inches. A compressing force of 370,000 lbs. was applied, or a little over 20 tons per square inch of section, when the pillar was shortened in length ·31 inch, and on the strain being relieved, it remained permanently shorter by ·15 inch. It appears from these and other experiments that the elastic strength of homogeneous iron and steel under compression is not equal to the elastic strength under extension, and this law applies more especially to thin tubes, which crumple up under a moderate strain. Mr. Hodgkinson found that a sheet-iron tube 4 inches square, 10 feet long, and ·03 inch thick, was crumpled up by a load of less than 5 tons per square inch of section.

The theory of the resistance of pillars, which is of great importance on account of its application to architectural purposes, was first investigated by Euler, according to whose hypothesis the strength varies directly as the fourth power of the diameter or side, and inversely as the square of the length. This law is confirmed by the experiments of Mr. Hodgkinson (*Phil. Trans.* 1840) in respect of pillars of wrought iron or timber; but in the case of pillars of cast iron, the powers of the diameter and length were somewhat different. Still Euler's doctrine was confirmed, that if the length of a column exceeds the diameter in a certain ratio, the column will bend and fail by breaking across in precisely the same manner as if it were subjected to a transverse strain. Mr. Hodgkinson found, from a mean of experiments, that a solid uniform pillar of cast iron, whose transverse section is one square inch, is destroyed by a weight of 98,922 lbs., or 44·16 tons. Assuming this as a unit of measure, he gives the following formula (as representing his experiments), in which s is the strength or weight in lbs. that would crush the solid pillar, d the diameter, and l the length; viz. $s = 980922 \times d^{3\cdot55} \div l^{1\cdot7}$. This formula applies to solid pillars of which the lengths are thirty-five times the diameter and upwards, and which are perfectly flat at the ends. When the ends of a pillar are rounded, so that the load bears only on the middle fibres, the strength is greatly reduced. In pillars whose length is thirty times the diameter or upwards, Mr. Hodgkinson found the strength of those with flat ends to be about three times greater than the strength of others of the same dimensions with round ends, the mean ratio being 3·167. In shorter pillars the ratio was not constant. The strength of a pillar is slightly increased by placing discs on the ends to increase the bearings.

In the case of hollow pillars of cast iron, it has been found that the 3·55 power of the internal diameter subtracted from the 3·55 power of the external diameter, and divided by the 1·7 power of the length, will represent the strength very nearly. In the case of hollow pillars or cylindrical tubes of wrought iron, it has been found that the 3·59 power of the internal diameter subtracted from the 3·59 power of the external diameter, and divided by the square of the length, gives a proper expression for the strength. But this rule holds

only when the strain does not exceed 8 or 9 tons on the square inch of section. Beyond 12 or 13 tons per square inch of section, the metal cannot be depended upon to withstand the strain, though 16 or 18 tons per square inch of section will sometimes be sustained. The power of plates to resist compression varies nearly as the cube, or, more accurately, as the 2·878 power of their thickness, the thinnest plates having the least strength. But this law holds only so long as the pressure applied does not exceed from 9 to 12 tons per square inch of section.

The power of iron to resist shocks will not be in all cases proportionate to its power to resist strains. Some cast iron is very hard and brittle, and although it will in this case resist compression, it will be easily broken by an oblique blow. Cast iron, of which the crushing strength is 42 tons per square inch of section, will, if remelted twelve times, bear a crushing weight of 70 tons, and if remelted eighteen times, will bear a crushing weight of 83 tons. But, taking its power to resist impact in its first state at 706, this power will be raised at the twelfth remelting to 1,153, and will be sunk at the eighteenth remelting to 149. Palliser's chilled shot derive most of their remarkable hardness and penetrating power from successive remelting and chilling.

Mr. Hodgkinson gives the following results of his experiments on the resistance to a crushing force of short pillars of some of the most common kinds of wood, the force being applied in the direction of the fibres.

Description of Wood	Strength per Square Inch, in Lbs.
Alder	6,831 to 6,960
Ash	8,683 — 9,363
Bay	7,518 — 7,518
Beech	7,733 — 9,363
English Birch	3,297 — 6,402
Cedar	5,674 — 5,863
Red Deal	5,748 — 6,586
White Deal	6,781 — 7,293
Elder	7,451 — 9,973
Elm	10,331
Fir (Spruce)	6,499 — 6,819
Mahogany	8,198 — 8,198
Oak (Quebec)	4,231 — 5,982
Oak (English)	6,484 — 10,058
Pine (Pitch)	6,790 — 6,790
Pine (Red)	5,395 — 7,518
Poplar	3,107 — 5,124
Plum (Dry)	8,241 — 10,493
Teak	12,101
Walnut	6,063 — 7,227
Willow	2,898 — 6,128

The results in the first column were deduced in each case from experiments upon cylinders of wood turned to one inch diameter and two inches long, flat at the ends. The wood was moderately dry. The second column gives the mean strength from similar specimens after being turned and kept dry in a warm place two months longer. The great difference in the strength frequently seen in the two columns shows strongly the effect of drying upon wood, and the great weakness of wet timber.

The tensile and crushing strengths of various materials, as determined by the best modern authorities, are recorded in the following table:

Tensile and Crushing Strengths of Various Materials per Square Inch of Section.

Material	Tensile Strength in Lbs. per Square Inch of Section	Crushing Strength in Lbs. per Square Inch of Section
Metals.		
Wrought-iron Bars	60,000	27,000 to 37,000
Wrought-iron Plates	52,000	varies as cube of thickness nearly
Wrought-iron Hoops (best)	64,000	
Wrought-iron Wire	70,000 to 100,000	
Cast Iron (average)	16,500	100,000
Cast Iron (toughened)	25,764	130,000
Steel	100,000 to 130,000	260,000
Cast Brass	18,000	10,000
Gun Metal	36,000	
Brass Wire	50,000	
Cast Copper	19,000	
Copper Sheets	30,000	
Copper Bolts	38,000	
Copper Wire	60,000	
Silver (Cast)	40,997	
Gold	20,490	
Tin (Cast)	4,736	
Bismuth (Cast)	3,137	
Zinc	7,000	
Antimony	1,062	
Lead (Sheet)	3,000	
Woods.		
Ash	17,000	9,000
Beech	12,000	9,300
Birch	15,000	6,400
Box	20,000	10,300
Elm	13,000	10,300
Fir (Red Pine)	10,000 to 14,000	5,375 to 6,200
Hornbeam	20,000	7,300
Lance-wood	23,000	
Lignum Vitæ	12,000	9,900
Locust	16,000	
Mahogany	8,000 to 16,000	8,200
Oak	10,000 to 19,000	10,000
Pear	9,800	"
Teak	15,000	12,000
Stones.		
Granite	— —	5,500 to 11,000
Limestone	— —	4,000 to 5,000
Slate	10,000 to 12,000	
Sandstone	— —	4,000 to 5,000
Brick (Weak)	— —	550 to 800
Brick (Strong)	—	1,100
Brick (Fire)	—	1,700
Glass	9,500	
Mortar	50	

Mr. Pole found the German steel wire used for pianofortes to bear as much as 268,800 lbs. per square inch.

The above values are for dry wood. In wet wood the crushing strength is only half as great.

The transverse strength of a beam or girder is determinable by a reference to the tensile and crushing strength of the material of which it is composed. Thus, if a cast-iron girder be supported at the ends and loaded in the middle, the bottom flange will be strained by extension

and the top flange by compression, and the flanges may be regarded as pillars, one of which must be crushed and the other torn before the beam can be broken. Now, as the crushing strength of cast iron is six times greater than its tearing strength, the lower flange of a cast-iron girder is made with six times the quantity of metal contained in the top flange, in order that the breaking forces may be in equilibrium, and so that one flange may not begin to tear before the other begins to crush. By this configuration the utmost strength will be obtained with the least material in the case of cast-iron beams. But as the crushing and tearing strengths of wrought-iron do not follow the same law, wrought-iron beams must not be similarly proportioned; and, in wrought-iron beams or girders, the top and bottom flanges are usually made of about the same cross section.

The clipping or shearing strain to which the cutters of steam engines and the pins of various structures are subjected is a form of tensile strain, as also is the twisting strain to which shafts are exposed. If we suppose a thin tube to possess a transverse section in which the particles cohere more weakly than in the other parts, and if we twist it as we twist the joints of a flute, it is plain that the tube will separate in the weak section, and all the particles in that section will be similarly strained; but if the tube be thick, the outside particles will be strained the most. The strength of solid shafts varies as the cube of the diameter, and the strength of hollow shafts as the cube of the external diameter diminished by the cube of the internal diameter.

Pillars.—If W be the breaking weight of a column or post in tons, l its length in feet, D its external diameter, and d its internal diameter if hollow, then for

Solid pillars of cast iron:

- both ends rounded, $W = 14{\cdot}9\,\dfrac{D^{3\cdot6}}{l^{1\cdot7}}$
- both ends flat, $W = 44{\cdot}16\,\dfrac{D^{3\cdot6}}{l^{1\cdot7}}$

Hollow pillars of cast iron:

- both ends rounded, $W = 13\,\dfrac{D^{3\cdot6} - d^{3\cdot6}}{l^{1\cdot7}}$
- both ends flat, $W = 44{\cdot}34\,\dfrac{D^{3\cdot6} - d^{3\cdot6}}{l^{1\cdot7}}$

Hodgkinson gives the powers as 35·5, but 3·6 is sufficiently near. For solid square pillars of Dantzic oak $W = 10{\cdot}95\dfrac{D^4}{l^2}$, and for similar pillars of red pine $W = 7{\cdot}81\dfrac{D^4}{l^2}$, where D is the side of the square. The safe load is about $\frac{1}{10}$ of the crushing load; the crushing strength of a long cast-iron column being taken at 1,000, that of wrought iron is usually reckoned as 1,745, cast steel 2,518, oak 109, and red pine 78. But short columns of wrought iron, especially if hollow and thin, are much weaker than this proportion assumes. In hollow columns the thickness of the metal should not be less than $\frac{1}{12}$ the diameter.

Girders.—If D = depth of a cast-iron girder at centre in inches, A = area of bottom flange in square inches, S = span in feet, and W = breaking weight in tons; then if the girder be supported at both ends and the load be placed in the middle, $W = \dfrac{25\,A\,D}{S}$, or the breaking weight will be just half of this if the load be equally distributed along the length. A safe deflection is $\frac{1}{40}$ of an inch for each foot in length under a test load of $\frac{1}{3}$ the breaking weight. The working load is never less than $\frac{1}{6}$ the breaking weight in the case of moving loads.

In the case of wrought-iron girders formed of riveted plates, $W = \dfrac{80\,A\,D}{S}$ and area of top flange $= 1{\cdot}18$ A. Wrought-iron girders are now often rolled, and the breaking weights of such girders at 10 feet span are as follow: Depth of girder, or D, 5 inches; size of flange, or F, 2 by $\frac{1}{2}$ inch; breaking weight, or W, 6·6 tons; D 6 inches, F $2\frac{1}{2}$ by $\frac{1}{2}$ inch, W 10 tons; D 7 inches, F 3 by $\frac{1}{2}$ inch, W 14 tons; D 8 inches, F 3 by $\frac{5}{8}$ inch, W 20 tons; D 9 inches, F 4 by $\frac{3}{4}$ inch, W 36 tons; D 10 inches, F $4\frac{1}{2}$ by 1 inch, W 60 tons. With double the span the breaking weights will be just half the foregoing, and so in all other proportions.

Shafts.—The following results, showing the comparative strength of various metals, as ascertained by resistance to torsion, is given by Mr. Rennie. For the law according to which the elasticity is evolved in the case of slender metallic wires or threads of fibrous substances, when the twisting force is less than is necessary to produce a permanent change of structure, see TORSION.

Lead	1,000
Tin	1,438
Copper	4,312
Brass	4,688
Gun metal	5,000
Swedish iron	9,500
English iron	10,125
Cast iron	10,600
Blister steel	16,688
Shear steel	17,063
Cast steel	19,562

Mr. Banks (*On the Power of Machines*) states, as the mean result of several experiments, that a bar of cast iron, one inch square, is wrenched asunder by a weight of 631 lbs. avoirdupois, applied at the extremity of a lever two feet in length. Other experiments on the force of torsion are given by G. Bevan (*Phil. Trans.* 1829) and Savart (*Annales de Chimie*, August 1829).

If the power of a solid cylinder to resist torsion be taken as 1, then the power of a solid square to resist it formed with an equal cross section will be ·87; of a hollow cylinder whose external is to its internal diameter as 4 to 10 is 1·26; as 5 to 10 it is 1·44; as 6 to 10 it is 1·7; as 7 to 10 it is 2·08; and as 8 to 10 it is 2·75,

Hence, hollow shafts are much stronger than solid ones with the same weight of metal.

If L = length of lever in inches to which the force employed to twist a shaft is applied; F = the force applied in lbs.; and D = diameter of shaft if round: then $D = \sqrt[3]{\frac{FL}{1500}}$ for cast iron; $D = \sqrt[3]{\frac{FL}{1700}}$ for wrought iron; and $D = \sqrt[3]{\frac{FL}{3200}}$ for cast steel.

The rule employed by Mr. Watt for determining the proper diameter of the cast-iron fly-wheel shafts of his steam engines is indicated by the following formula: If a be the area of the piston in square inches, p the pressure on each square inch of the piston, and l the length of the crank in feet: then $\sqrt[3]{\frac{apl}{31\cdot4}}$ = the proper diameter to be given to the shaft in inches.

Strepsipterans (a word coined from Gr. *στρέψις, a turning*, and *πτερόν, a wing*). The name given by Kirby to the order of insects which he found to possess rudimental elytra in the form of linear and spirally twisted scales.

Strepsirhina (Gr. *στρέψις*, and *ῥίς, ῥινός, the nose*). A family of Quadrumana, in which the nostrils, situated at the extremity of the nose, are twisted, whence the name. It comprises two subfamilies, the *Lemuridæ* and the *Galeopithecidæ*, which are again divided into various genera, of which *Lichanotus*, *Propithecus*, *Perodicticus*, *Nycticebus*, *Loris*, *Lemur*, *Chirogaleus*, *Otolicnus*, *Microcebus*, *Tarsius*, *Cheiromys*, and *Galeopithecus*, are variously distributed, the metropolis of the family being Madagascar.

Stretcher. In Architecture, a block of stone, or a brick, laid horizontally with its length in the direction of the face of a wall. A stretching course has the bricks or stones in its composition laid horizontally with their length in the direction of the wall. [HEADERS; HEADING COURSE.]

Stretchers. Movable bars across the bottom of a boat for the rowers to place their feet against. The power of the stroke is dependent on the proper adjustment of the stretcher.

Stretching Course. In Architecture, a course in which the bricks or stones are laid horizontally with their lengths in the direction of the face of the wall. [HEADERS; HEADING COURSE.]

Stretching Machine. Calicoes, and other similar textile fabrics, are prepared for the market by being stretched in a proper machine, which lays all their warp and woof yards in parallel positions, and extends their width after the shrinkage caused by bleaching, dyeing, &c.

Stretto (Ital. from Lat. strictus, *strait*, *narrow*). In Music, a term indicating that the measure to which it is affixed is to be performed short and concise, hence quick. It is the opposite of *largo*. The stretto of a fugue is a part coming towards the end, where the answers to the subject are brought more closely together.

Striate (Lat. stria, *a channel* or *furrow*). In Zoology, when a surface is painted or impressed with several narrow transverse streaks.

Striction, Line of. The line of striction on a skew ruled surface is the curve which cuts each generator in the point of the latter which is nearest to the consecutive generator. The line cutting, perpendicularly, two consecutive generators, and upon which their shortest distance is measured, is not itself, in general, a tangent to the line of striction; for the point on a generator nearest to the succeeding one is not necessarily nearest to the preceding one. Such lines, in fact, are generators of a second *conjugate* ruled surface circumscribed to the original one along a curve which is a line of striction on both surfaces. The point in which the line of striction cuts any generator is called the *central point* of the latter; the rectangle is constant whose sides are equal to the distances from this central point to the two points at which any plane through the generator is respectively tangential and normal to the surface; and the normal plane through a generator at its central point touches the surface at infinity. [SKEW SURFACE.] The ruled surfaces of the second order have two systems of rectilinear generators and, of course, a line of striction corresponding to each system. In the hyperbolic paraboloid, for instance, the two lines of striction are parabolas whose planes intersect in the principal axis. In conoid surfaces the rectilinear directrix to which all generators are perpendicular is the line of striction. A familiar instance is the under surface of a spiral staircase; the central axis of the staircase is here the line of striction.

Strigæ (Lat. *furrows*). In Architecture, the flutings of a column.

STRIGÆ. In Botany, close-pressed rigid hairs distributed over the surface. Hence plants furnished with such hairs are said to be *strigose*.

Strigidæ. The name of the family of Nocturnal Raptores of which the owl (*Strix*) is the type.

Strike. Part of the machinery of TRADES' UNIONS. When the executive or committee of an organisation for securing certain advantages to labourers decides that the workmen shall discontinue labour till their claims are satisfied, the act of the labourers is called a *strike*; when, on the other hand, the masters resolve to resist the action of labourers and to enforce certain conclusions which they have come to, and therefore suspend their works, the proceeding is called a *lock-out*.

STRIKE. [DIP AND STRIKE.]

Striking a Tent. Taking down a tent which has been erected or *pitched*.

String (A.-Sax.; Ger. strang). In Music, a cord of some elastic material, which being tightly stretched over two bridges (giving a definite length) and set in vibration, gives a

musical sound. The strings of the violin tribe, and of the harp and guitar, are of catgut; those of the pianoforte are of steel wire. The note sounded by a stretched string depends on three elements; viz. the length and the weight of the vibrating portion, and the tension with which it is stretched. If l = length in inches, and w = weight in lbs. of the vibrating part of the wire; T = the tension, or stretching weight in lbs.; and V = the number of single vibrations per second; then

$$V^2 = 386 \ . \ 156 \frac{T}{lw}.$$

String Board. In Architecture, a board with its face next to the well-hole of a wooden staircase, which receives the ends of the steps; it differs from the *wall string* in its position, the one being near the end wall bearing of the steps, and the other being the outside, or the framing towards their outer end.

String Course. In Architecture, this term is applied to a course running round the face of a building, the projection of which is small in proportion to its height.

Strisores (a word coined from Lat. strideo, *to hum* or *buzz*). An order of birds in the systems of Cabanis and Lilljeborg, including the humming-birds, swifts, night-jars, and kingfishers.

Strobilus (Lat.; Gr. *στρόβιλος*, *anything twisted up*). In Botany, this term is used in describing a fir-cone, which may be defined as a spike of very imperfect flowers, subtended by bracts which are woody and pressed closely to each other. It thus indicates an imbricated scaly inflorescence, or any collection of hard scales, representing distinct flowers arranged spirally, but closely imbricated. The term is applied to any fruit which resembles a fir-cone.

Stroganowite. An altered form of Scapolite, found in loose blocks near the river Sljudänkä in Dauria, of a greyish-white or greenish colour. It is a silicate of alumina, lime, and soda, with about 15 per cent. of chloride of lime. Named after Count Stroganow.

Strombus (Lat.; Gr. *στρόμβος*, literally *a rounded body*, from *στροβέω* and *στρέφω*, *to turn*). The name of a shell-fish in Pliny. This term was applied by Linnæus to a genus of the Vermes Testacea, characterised by the form of the shell, of which the aperture is much dilated, the lips expanding, and produced into a groove leaning to the left. The Mollusca to which this character is applicable form a group of Pectinibranchiate Gasteropods in the system of Cuvier, which has been subdivided into the genera *Strombus* proper, *Pterocera*, Lam., &c.

Stromeyerite. A double sulphide of silver and copper, composed of 15·7 per cent. of sulphur, 52·9 silver, and 31·4 copper. It is isomorphous with Copper Glance, but also occurs compact, of a dark steel-grey colour, with a strong metallic lustre, and is sectile and very brittle. It is found in Siberia, Silesia, Chili, and Peru. Named after Stromeyer, who analysed it.

Stromite. A variety of Diallogite, called after a director of mines of the name of Strom.

Stromnite. A sulphate of baryta and carbonate of strontia: probably a mixture merely of the sulphate and carbonate, found at Stromness in Orkney. It occurs in yellowish-white translucent masses, with a slight pearly lustre, and crystalline cleavage.

Strongylus (Gr. *στρογγύλος*, *round*). A genus of intestinal worms in Rudolphi's classification, characterised by having a cylindrical body, the anal extremity of which, in the male, is surrounded by a kind of pouch of a varied shape, from which is protruded a small filament or spiculum, probably subservient to generation. The mouth is orbicular, sometimes armed with spines, as in the *Strongylus armatus*, which infests the mesenteric arteries of the horse and ass, producing aneurisms; sometimes the mouth is surrounded by tubercles or papillæ, as in the *Strongylus gigas*, which is sometimes found in the kidney of the human subject.

Strontia. An earth contained in a mineral, generally of a pale green tint and radiated crystalline texture, found at Strontian in Argyleshire. It is a carbonate of strontia. Strontia is the oxide of a metallic base, the properties of which are very imperfectly known, called *strontium*; the equivalent of strontia, or oxide of strontium (composed of 44 strontium and 8 oxygen), is 52. It has a caustic taste, an alkaline reaction, and a degree of solubility in water intermediate between lime and baryta. The salts of strontia are generally obtained by dissolving the natural or artificial carbonate in the acids; those which are soluble give the flame of burning bodies a fine rose-red colour: the nitrate of strontia is used for this purpose, and with beautiful effect, in theatrical exhibitions and fireworks. The sulphate of strontia is found native: it is an insoluble white powder when artificially prepared. Some of its native varieties have a pale blue tint, whence the term *cœlestine*. Very beautiful crystals of this variety have been found in the New Red Marl of Clifton and in the neighbourhood of Bristol. A colourless prismatic crystalline variety, of great beauty, is found associated with the native sulphur of Sicily.

Strontianite. Native carbonate of strontia. [STRONTIA.] It occurs in hexahedral prisms which are modified at the edges or terminated by pyramids; also in fibrous, stellated, columnar, globular and granular masses of a green colour; also white, yellow, grey, or brown. It is found at Strontian in Argyleshire, generally in acicular diverging groups of crystals, and in snow-white crystals at Pately Bridge and Nidderdale in Yorkshire. The principal foreign localities are Saxony, Westphalia, the Harz, and the Northern States of America.

Strontianocalcite. A variety of carbonate of lime containing an admixture of strontia.

Strontites. [STRONTIANITE.]

Strophe (Gr. *στροφή*, *a turning*). A division of a Greek choral ode answering to a stanza. The name is derived from *στρέφειν*, *to turn*,

because the singers turned in one direction while they recited that portion of the poem; they then turned round and sang the next portion, which was of exactly the same length and metre as the preceding, and was termed the *antistrophe*. These were sometimes followed by another strophe and antistrophe, sometimes by a single stanza called the EPODE.

Strophiolæ. [CARUNCULA.]

Strophulus (a word coined from the Greek στρέφω, *to turn*, and οὖλα, *the gums*). The *red gum*; an eruption peculiar to infants.

Struma (Lat.). In Botany, a swelling present in some leaves at the extremity of the petiole, where it is connected with the lamina, as in *Mimosa sensitiva*. The term is also used in describing mosses to denote a dilatation or swelling sometimes seen upon one side of the base of the theca.

STRUMA. In Pathology, an enlarged gland.

Strut. In Architecture, a piece of timber placed obliquely to the foot of a king post or a queen post to support a rafter; it is sometimes called a *brace*. The term is also applied to the raking shores inserted to support a building.

Struthein (Gr. στρουθίον, *soap-wort*). A principle obtained from the root of *Gypsophila Struthium*. It appears to be identical with *Saponin*, obtained from the *Saponaria officinalis*, or Soap-wort.

Struthionidæ (Lat. struthio, Gr. στρουθίων, *an ostrich*). The name of a family of terrestrial birds, incapable of flight, with very short or rudimental wings, and long and strong legs; including the ostrich and other congeneric species which constitute the order *Cursores* of Kirby, and the family *Brevipennes* in the system of Cuvier.

Struvite. A name given (in honour of Struve) to the crystallised ammonio-magnesian phosphate found in peat-earth in digging the foundations of the church of St. Nicholas at Hamburg, and which is also met with in guano at Saldanha Bay, on the coast of Africa. It occurs in regular six-sided prisms of a pale yel'ow colour, which are transparent, but generally rendered opaque and blackened by organic matter.

Strychnia or **Strychnine** (Gr. στρύχνος, *nightshade*). A poisonous vegetable alkaloid, discovered in 1818 by Pelletier and Caventou in the seed of the *Strychnos multiflora* [IGNATIUS'S BEAN] and *S. nux vomica*, and also in the Upas poison. Its composition is represented by $C_{42}H_{22}O_4N_2$. To obtain it, the nux vomica seeds are boiled for some hours with water acidulated by one-eighth of its weight of sulphuric acid; they are then bruised, and the liquor expressed. Excess of lime is then added to it, and the precipitate boiled in alcohol of sp. gr. ·850, and filtered hot; strychnia and brucia are deposited together in a coloured and impure state, and may be separated by cold alcohol, which dissolves the brucia. The remaining strychnia is then boiled in alcohol with a little animal charcoal, and the solution filtered boiling hot; on cooling, the strychnia crystallises. The same process is applicable to the Ignatius' beans.

Strychnia is a powerful poison, destroying life with the dose of half a grain. It is a white crystalline solid. It requires 7,000 parts of cold and 2,500 of boiling water for solution: the intensity of its bitterness is such, that an aqueous solution containing not more than $\frac{1}{10000}$ of its weight of strychnia is sensibly bitter. It is soluble in common alcohol, especially at its boiling temperature, and crystallises in prisms and octahedra from this solution. It is dissolved by the acids, forming colourless and crystallisable salts. It is not soluble in the alkalies. Nitric acid does not colour strychnia or its salts, if free from brucia; but it frequently reddens them, owing to traces of brucia.

When a minute quantity of strychnia is moistened with a drop of concentrated sulphuric acid, the strychnia is dissolved without any peculiar colour; but if a minute quantity of peroxide of lead or manganese, or of bichromate of potash, is added, a blue tint is developed, which passes into red and yellow. This reaction is characteristic of strychnia.

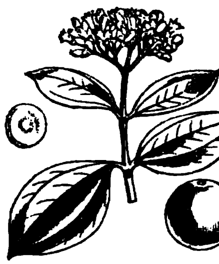
This alkaloid neutralises the acids, and forms very bitter and poisonous salts: they are mostly crystallisable. The caustic alkalies throw down from their solutions a white precipitate of strychnia, which may be dissolved and removed by agitating the liquid with twice its bulk of ether or chloroform. This is the process usually pursued for the extraction of strychnia in cases of poisoning. The liquid is acidulated, concentrated in a water-bath, rendered alkaline by potash, and then shaken with two volumes of ether. The ethereal liquid poured off, and spontaneously evaporated, leaves strychnia.

The symptoms of poisoning by strychnia are difficulty of breathing and sense of suffocation, twitching of the limbs, and violent tetanic convulsions, the body becoming stiff, arched in the back, and resting on the head and heels; the features are convulsed, and attempts to drink are often attended by spasm of the jaws and choking. During the intervals of the paroxysms the intellect is usually clear, but after a succession of fits and shortly before death, there may be loss of consciousness. The only chance of recovery appears to be the very early use of the stomach pump. Medicinally, the extract or tincture of nux vomica is used in certain forms of paralysis and indigestion; and in small doses it acts as a tonic and diuretic. (Taylor *On Poisons*.)

Strychnos (Gr. στρύχνος). A genus of *Loganiaceæ*, consisting of trees or climbing shrubs, natives of the tropics of Asia and America. They have entire strongly-nerved opposite leaves, one of them frequently abortive, and developing from its axil a tendril-like branch; and they bear terminal or axillary corymbs or panicles of greenish-white, generally fragrant flowers. The seeds are flattened, disc-like, and silky, surrounded by pulp.

S. nux vomica is the species which yields the

seeds known under the name of *Nux vomica*. It is a moderate-sized tree, with fruit very like an orange in appearance, and containing numerous seeds of a flattened circular outline, about



Strychnos nux vomica.

the size of a halfpenny, rather thicker near the circumference than elsewhere, the exterior of an ash-grey colour, covered with fine silky hairs, and the interior consisting of very hard grey albumen, in which, near the circumference, the embryo is embedded. The seeds have an intensely bitter taste, owing to the presence of two most energetic poisons, STRYCHNIA and BRUCIA, conjoined with certain peculiar acids; but the pulp is innocuous, and is said to be greedily eaten by birds. The bark of the tree possesses similar properties to the seeds, but in less degree. Serious consequences ensued in the early part of the present century from this bark having been imported and used as Angostura bark; and in Calcutta it is said to be sold for the harmless bark of *Soymida febrifuga*, or Rohun bark.

S. Tieuté, a climbing shrub, growing in Java, yields a juice which is used by the natives for poisoning their arrows. Its effects are precisely similar to those of nux vomica. This poison is called Upas Tieuté. *S. toxifera* also yields a frightful poison called OURARI or Wourali, employed by the natives of Guiana. It has been tried in cases of hydrophobia, but with no good result. *S. Colubrina*, a native of Malabar, furnishes one kind of Snakewood: it is considered by the natives as an infallible remedy in cases of snake-bite; it is also given in fevers and other complaints. *S. ligustrina* and other species are said to yield in Java various kinds of Snakewood, used for similar purposes. *S. Pseudo-Quina*, a native of Brazil, yields Colpache bark, which is largely used in that country in fever cases, and is considered to equal quinine in value; its fruit is edible. It is stated that this species does not contain strychnia, in spite of its bitter taste, and hence it is not considered to be poisonous.

S. potatorum, a tree found in the mountains and forests of India, yields the seeds known in that country as Clearing Nuts. The fruit is black, of the size of a cherry, and contains only a single seed. These seeds are employed to clear muddy water; they are simply rubbed round the inside of the vessel for a minute or two, and then the water is allowed to settle. Their efficacy for this purpose depends, according to Dr. Pereira, on their albumen and casein, which act as fining agents.

Stubble (Ger. stoppel, Lat. stipula). The root ends of stalks of corn, left in the field after the corn has been reaped. In some parts of the country only a small portion of the straw is cut off with the ears of corn, and the stubble in that case is a foot or eighteen inches in length; but in others the corn is cut as close to the surface as possible, and in this case the stubble is quite short. In general, long stubble is a symptom of bad farming, because a quantity of straw is thus left waste in the field, which might have been carried home and rotted into manure.

Stucco (Ital.). In Architecture, a term applied to many sorts of calcareous cements. In this country it denotes generally any third coat of three-coat plaster, consisting of fine lime and sand; the better sort is hand-floated twice, and well trowelled. There is a species called *bastard stucco*, in which a small portion of hair is used. [FINISHING.] *Rough stucco* is merely floated and brushed with water.

Studding Sails. Supplementary sails extended in light winds beyond the leeches of the principal square sails. They are narrow, and of the same height with the sail supplemented. Although not of great power from their size, they exert considerable force on the ship's movements from the leverage which their distance from the mast as centre gives them. They are bent on the studding-sail booms, which are spars run out as required along the upper surfaces of the yards.

Stufa (Ital.). A jet of steam issuing from a fissure in the earth: these jets are not uncommon in volcanic districts. The name is also applied to natural vapour baths, in which steam issues from the earth, generally accompanied by gas, and used for curative purposes.

Stuff (Dutch stof, Ger. stoff, Fr. étoffe). A Commercial term, applied to various woven fabrics; it signifies especially a light woollen cloth formerly much used for curtains and bed furniture.

Stuffing Box. A recess for the reception of packing or stuffing, usually of hemp, and provided with a lid and suitable bolts, by which the packing may be screwed down. The purpose of the contrivance is to enable a rod or shaft to pass through an orifice without any undue friction, and yet to keep the perforation tight. To this end, a stuffing box is provided where the piston rod of an engine passes through the cylinder cover, and also at the point where the screw shaft of a steamer passes through the stern beneath the water.

Sturgeon (Ger. stör, Span. esturion, Fr. esturgeon). The type of a genus of Cartilaginous fishes, with free gills, having the body more or less covered with bony plates in longitudinal rows. The mouth is placed beneath the snout, is small and edentulous, but protractile. Soft feelers or cirri are attached beneath the snout. The bodies of the vertebræ retain

the primitive condition of an undivided gelatinous cord. The sturgeons ascend the larger rivers of Europe in great abundance. The flesh of most of the species is wholesome and agreeable food; their ova are converted into caviare, and their air-bladder affords the finest isinglass.

The sturgeon which is occasionally captured on our east coast is the *Acipenser sturio* of Linnæus.

By statute 16 Edw. II. c. 1, all sturgeon, wherever caught, are declared to vest in the crown by virtue of their dignity, and are to be delivered without purchase. For the importance of the sturgeon fishery in the Caspian, see the *Commercial Dictionary*. No fish, with perhaps the exception of the cod and the herring, has so great an economical importance. [ACIPENSER.]

Sturionians. The name of the family of Cartilaginous fishes of which the sturgeon is the type.

Sturm's Theorem. This theorem, in the theory of equations, enables us to ascertain how many real roots of an equation lie between any given limits. It was communicated to the Academy of Paris, and published in the *Mémoires présentées par des Savants Etrangers* in 1835. In the enunciation of the theorem, to which we shall here limit ourselves (its demonstration being given in every good text-book), it will be necessary to refer to the series of *Sturmian Functions* $F(a)$, $F_1(x)$, . . . $F_m(x)$. The first, $F(x)$ is the function which, put equal to 0, constitutes the given equation, deprived of its equal roots [EQUATIONS, THEORY OF]; and the second $F_2(x)$ is the derived function of $F(x)$. To obtain the other functions, the operation of finding the greatest common measure of $F(x)$ and $F_1(x)$ must be performed with these modifications: 1. The multipliers usually employed in order to avoid fractional coefficients must all be *positive numbers*; 2. The signs of all the coefficients in each remainder must be changed before making it a divisor; 3. The process may be arrested at any such modified remainder $F_m(x)$ which has the property of retaining the same sign for all values of x. This being premised, Sturm's theorem may thus be enunciated: The number of real roots of the equation $F(x)=0$ between given limits a and b is equal to the difference between the numbers of variations of sign presented by the series of Sturmian functions $F(a)$, $F_1(a)$, $F_2(a)$ . . and $F(b)$, $F_1(b)$, $F_2(b)$ . . Thus, if

$$F(x)=x^4-3x^3-2x^2+x-3,$$

we shall have

$$F_1(x)=4x^3-9x^2-4x+1,\ F_2(x)=43x^2+45_9,$$

which is necessarily positive. Putting, for x, $-\infty$ 0, and ∞, successively, the variations in signs presented by the series of three Sturmian functions amount respectively to 2, 1, and 0; hence the equation has two imaginary and two real roots, one of the latter being positive and the other negative. Valuable memoirs on questions relating to Sturm's theorem have been published by Prof. Sylvester; one of these, in the *Philosophical Transactions* for 1853, will well repay the attentive perusal of all students of the higher algebra.

Stuttering. [STAMMERING.]

Stye or **Stythe.** A little boil or tumour projecting from the edge of the eyelid.

Stygmite. A name for a variegated variety of Carnelian of a reddish-yellow colour, and traversed by numerous white lines.

Style (Ital. stile, Ger. stil, Lat. stilus). In Botany, that elongation of the ovarium which supports the stigma. It is an extension of the midrib of the carpellary leaf, or is formed by the rolling up of the attenuated extremity of the latter.

STYLE. In the Calendar, a manner of reckoning time. For the new style introduced by Gregory XIII. in 1582, and adopted by England in 1752, see CALENDAR.

STYLE. In Dialling, the gnomon which projects the shadow on the plane of the dial. [DIAL.]

STYLE. In the Fine Arts, the mode in which an artist forms and expresses his ideas on and of a given subject. It is the form and character that he gives to the expression of his ideas, according to his particular faculties and powers, or his *handwriting*. Style may be almost considered as the refinement of MANNER: it is a characteristic essence by which we distinguish the works of one master from another. From literature this word has passed into the theoretic language of the fine arts; and as in the former we hear of the *sublime*, *brilliant*, *agreeable*, *regular*, *natural*, *confused*, and other styles, so we have almost the same epithets applied to styles of art. Nor is this remarkable, since the principles of taste, in both the one and the other, are founded in nature; and it is a well-known saying, that poetry is a speaking picture. This word is improperly used as applied to colouring and harmony of tints: we speak of the style of a design, of a composition, of draperies, &c.; but not of the style of colouring, but rather the *method* or *manner* of colouring. The definition of this word by Sir Joshua Reynolds is as follows: 'Style in painting is the same as in writing—a power over materials, whether words or colours, by which conceptions or sentiments are conveyed.' But we can scarcely consider this definition sufficiently general; it is rather the *individuality* of the mode of applying this power. There is in art what is called *subjective* and *objective* style. [DECORATION; ORNAMENT; SUBJECTIVE.]

STYLE. A kind of pencil made use of by the Romans for writing on waxed tablets. It was made of brass or iron, with one end sharp for writing, and the other blunt and smooth for making erasures; hence the phrase *to turn the style*, used by ancient writers, signifies to make corrections.

Styles. [RAIL. In Architecture.]

Stylidiaceæ (Stylidium, one of the genera). A small order of monopetalous epigynous Exo-

gens, nearly allied to the irregular-flowered *Campanulaceæ* or *Lobeliaceæ*, of which it has the inferior two-celled ovary and capsular fruit, with numerous albuminous seeds; but it is remarkable for the stamens, two in number, being united with the style in a highly irritable column of curious structure, the stigma lying in a cavity at the apex, surrounded and concealed by the anthers. It consists of small herbs or undershrubs, chiefly Australian. The genus *Stylidium* itself contains the great majority of the species.

Stylite (Gr. στυλίτης, from στῦλος, *a column*). The title given to a peculiar class of anchorites from the places on which they took up their solitary abodes, being the tops of various columns in Syria and Egypt. This strange method of devotion took its rise in the second century, and continued to be practised for a great length of time. The most famous among them was one Simeon, in the fifth century, who is said to have lived thirty-seven years upon various columns of considerable height in the neighbourhood of Antioch. (Montalembert, *Les Moines d'Occident*; *Edinburgh Review*, October 1861, p. 329.)

Stylo. In Physiology, names compounded of this word apply to the muscles attached to the styloid process of the temporal bone.

Stylobate (Gr. στυλοβάτης, *the foot of a column*). In Architecture, the uninterrupted base below a range of columns.

STYLOBATE. A Mineralogical synonym for GEHLENITE.

Styphnic Acid (Gr. στυφνός or στρυφνός, *astringent*). An astringent acid compound obtained by the action of nitric acid upon certain gum resins. It is also called *Nitro-styphnic acid.*

Stypticite. A Mineralogical name for the fibrous form of yellow copperas or Copiapite.

Styptics (Gr. στυπτικός, from στύφω, *to draw together*). In Medicine and Surgery, remedies used for checking the flow of blood. Alum and tannic acid are powerful styptics.

Styracaceæ (Styrax, one of the genera). An order of perigynous Exogens, consisting of trees or shrubs, chiefly tropical, with alternate undivided leaves without stipules, and solitary clustered or paniculate flowers. They are known by their monopetalous flowers, their epipetalous stamens, their long radicle and leafy cotyledons, and by a part at least of the ovules being suspended. The two principal genera, *Symplocos* and *Styrax*, are considered by some botanists as types of two distinct orders.

Styrax officinale, a native of the Levant, &c., yields a balsamic resinous substance known as Storax, which is obtained by stripping off pieces of the bark of the shrub, and submitting them to pressure. In this way liquid storax is obtained. Solid storax appears to be the same substance mixed with fine sawdust and dried. Storax is used by perfumers on account of its agreeable odour, and it is employed in medicine as a stimulating expectorant.

S. Benzoin, a native of Sumatra, Borneo, &c., yields the resin called Benzoin. The juice exudes from incisions made in the trees, and when dried is removed by a knife or chisel. Each tree yields annually about three pounds of benzoin, that which is formed during the first three years being of better quality than that which exudes subsequently. Benzoin is used medicinally in chronic pulmonary disorders, and by perfumers for various purposes. It is also used in the composition of incense.

Styrax. [STORAX.]

Styrole. An oily hydro-carbon obtained by distilling liquid storax. It is perfectly liquid, but has the curious property of becoming a soft viscid transparent solid when heated. In this state it has been called *metastyrole.* The formula of styrole is $C_{16}H_8$.

Styx (Gr. Στύξ, *the hateful*). In the Hesiodic *Theogony*, a daughter of Oceanus and Thetis. This river, Styx, was one of the ten arms or branches of Oceanus. The gods of Olympus swore by the water of Styx, as her reward for aiding Zeus against the Titans. [ACHERON; COCYTUS; LETHE; PHLEGETHON.]

Sub-Apennine Formation. An important group of fossiliferous rocks of the newer Tertiary period, developed on the flanks of the Apennines. They consist of marls containing calcareous matter, and alternating with sand. Near Parma they have a thickness of 2,000 feet. They are very rich in fossil shells of species identical in many cases with those of our crag.

Sub-contrary. In the Scholastic Logic, this term expresses the opposition between two propositions, one of which is a particular affirmative (I), and the other a particular negative (O). [LOGIC.]

Sub-contrary Section. In Geometry, if an oblique cone on a circular base be cut by a plane not parallel to the base, but inclined to the axis, so that the section is a circle, then the section is said to be *sub-contrary.* The part of the cone thus cut off is similar to the whole cone; the plane of the section and the base of the cone being equally inclined to the axis.

Sub-Lieutenant. In the Royal Navy, the rank among combatant officers next below lieutenant, and the first—having a commission—which the youngster attains after entering the service. The former title was MATE.

Subahdar. The Hindu name for the governor of a subah or province. It is also applied to native officers of the Indian army, ranking as captain in European companies.

Subaltern (Lat. sub, *under*, and alternus, *alternate*). Literally an inferior officer, but the name is generally applied to all commissioned officers under the rank of captain. [ENSIGN; LIEUTENANT; &c.]

SUBALTERN. In Logic. [PROPOSITION.]

Subbrachians (Lat. sub, and brachium, *the arm*). The name of the order of Malacopterygious fishes comprising those which have the ventral fins situated either immediately

beneath and between, or a little in front or behind, the pectoral fins.

Subclavian. An Anatomical term applied to vessels, nerves, &c. under the shoulder or armpit.

Subdominant (Lat. sub, *under*, and dominans, *governing*). In Music, that note which is a fifth below the key-note. It is a species of governing note, inasmuch as it requires the tonic to be heard after it in the plagal cadence. In the regular ascending scale of seven notes it is the fourth; the term, however, has its origin from its relation to the tonic as the fifth below.

Subduplicate Ratio. In Arithmetic and Algebra, the subduplicate ratio of two numbers is the ratio of their square roots. Thus, the subduplicate ratio of the numbers 9 and 16 is the ratio of 3 to 4; and of the numbers a and b, it is the ratio of $\sqrt{a}$ to $\sqrt{b}$.

Suber (Lat. the *cork-tree*). The substance known as Cork. It is the epiphlœum of bark, when it acquires an elastic soft texture, and is preternaturally enlarged.

Suberic Acid (Lat. suber, *cork*). An acid substance into which cork is converted by the long-continued action of nitric acid.

Suberin. A name given by Chevreul to the cellular tissue of cork after the various soluble matters have been removed by the action of water and alcohol.

Subgenus. When the species of a genus are so numerous and diversified as to offer characters by which they may be ranged into groups these are termed *subgenera*.

Subinfeudation. In Feudal Law, subinfeudation denotes the creation by a feudal tenant of a subordinate tenancy, to be held of *him* and not of his superior lord. [FEUDAL SYSTEM; TENURE.]

Subito (Ital. and Lat. *suddenly*). In Music, a term of direction; as volti subito, *turn* [the leaf] *quickly*.

Subject (Lat. subjectus, part. of subjicio, *I throw under*). In the Fine Arts, that which it is the desire and aim of the artist to express.

Subject of a Proposition. In Logic, the term of which the other is affirmed or denied. [LOGIC; PROPOSITION; TERM.]

Subjective. In Painting, the term *subjective* is now sometimes used in criticism to indicate that the representation of an object or event is modified by, or *subjected* to, the idiosyncrasy of the artist; and this is in contradistinction to *objective*, when the object is represented with strict individuality. Rubens and Rembrandt were *subjective* painters; the Dutch and Flemish painters of still life, on the other hand, have been *objective* in their works.

Subjective and Objective. Terms expressing the distinction which in analysing every intellectual act we necessarily make between ourselves, the conscious *subject*, and that of which we are conscious, the *object*. 'I know,' and 'something is known by me,' are convertible propositions; every mental act which is not thus resolvable belongs to the emotional part of our nature, as distinguished from the intelligent and percipient. For the distinction between subject and object, the neglect of which has been the cause of infinite confusion and perplexity, we are indebted to the schoolmen, from whom it was derived (through Wolf and Leibnitz) by Kant and the modern German philosophers.

Sublapsarians or **Infralapsarians.** In Ecclesiastical History. The greater number of the divines of the reformed or Calvinist churches have held that God *permitted* the fall of Adam, without positively predetermining it; a doctrine which has been termed *sublapsarian*, in opposition to the high Calvinistic or *supralapsarian* view. [SUPRALAPSARIANS.]

Sublimation (Lat. sublimis, *on high*). A process by which solids are by the aid of heat converted into vapour, which is again condensed, and often in the crystalline form. This operation is frequently resorted to for the purpose of purifying various chemical products, and separating them from substances which are less volatile.

Sublime (Lat. sublimis). In the Fine Arts, high or exalted in style. Sublimity is incompatible with our ideas of elegance, grace, or any of the other sources of beauty, though these may all enter into an object in which these and many other qualities may be combined with sublimity. They have been, however, not unfrequently considered as some of the sources of the sublime. The nod of Jupiter, in the hands of such a master as the Homeric poet, is an indication of sublimity; but when Longinus tells us, that, as applied to literature, the constituent ingredients of sublimity are boldness in thought, the pathetic, proper application of figures, use of tropes and beautiful expressions, and, lastly, musical structure and sounds, we are inclined to think he had very indistinct notions of it himself. We cannot better exemplify the meaning of this term than by referring the reader to the works of Michael Angelo in the Sistine Chapel, wherein, according to Fuseli, 'his line is uniformly grand; character and beauty were admitted only as far as they could be made subservient to grandeur. The child, the female, meanness, deformity, were by him indiscriminately stamped with grandeur. A beggar rose from his hand the patriarch of poverty; his infants teem with the man, his men are giants.' The *terribile via*, hinted at by Agostino Caracci, is the sublime.

Sublingual Glands (Lat. sub, *under*; lingua, *tongue*). A pair of small salivary glands beneath the tongue, the secretion of which is more viscid than that of the parotid glands, and serves to facilitate the passage of the food through the fauces and gullet.

Submarine Telegraph. [TELEGRAPH, SUBMARINE.]

Submaxillary Glands (Lat. sub, *under*, and maxilla, *jaw*). A pair of salivary glands larger than the submaxillary situated beneath or rather behind the lower jaw, but emitting

their secretion, which resembles that of the sublingual glands, below the tongue.

Submediant (Lat. sub, *under*, and medius, *middle*). In Music, the middle note between the tonic and subdominant descending. It is the greater sixth in the major scale, and the lesser sixth in the minor scale.

Submultiple. In Arithmetic and Geometry, the same with *aliquot part* or *measure*; or it is such a part of a quantity as can be expressed by a whole number, as a third, a fourth, &c.

Subnormal (Lat. sub, and norma, *a rule*). In Geometry, that part of the axis of a curve line which is intercepted between the ordinate and the normal. If y be the ordinate, and x the absciss of any curve, the expression for the subnormal is $y\frac{dy}{dx}$. The subnormal is always a third proportional to the subtangent and the ordinate. The term *polar subnormal* has reference to polar co-ordinates, and is applied to the line drawn from the pole perpendicular to the radius vector to meet the normal; its expression is $\frac{dr}{d\theta}$.

Subordinary. In Heraldry, according to some writers on this imaginary science, an ordinary, when it comprises less than one-fifth of the whole shield, is termed a *subordinary*.

Subordination. [TRACERY.]

Subornation (Lat. sub, and orno, *I provide, furnish, procure*; a meaning not classical). Subornation of perjury, in Law, is the procuring a man to take a false oath amounting to perjury. The offence of subornation is not complete unless the oath be taken; but it is a misdemeanour to attempt to procure false testimony.

Subpoena. In Law, a writ of which there are several sorts. *Subpœna ad testificandum* is the common process, both in equity and in the courts of common law, to compel the attendance of a witness. *Subpœna duces tecum* is a writ of the same nature with the former, with a clause requiring the witness to bring with him and produce books and papers. An action of damages lies against parties disobeying this writ.

Subrogation (Lat. subrogo). In Civil Law, the substitution of one person for another in the exercise of rights (whence SURROGATE), but, in particular, the substitution by a creditor of another party to exercise his rights against the debtor.

Subscapular (Lat. sub, *under*; scapula, *blade-bone*). Muscles, vessels, nerves, &c., that lie or pass beneath the scapula.

Subsidence (Lat. subsido, *I sink down*). In many parts of England and elsewhere there is evidence of a depression of the land having taken place, not perhaps within the historic period, but still so recently as to be little, if at all, beyond human experience. As raised beaches are evidences of elevation, so peat and submerged beds of vegetable matter near a sea-coast are proofs of this depression or *subsidence*. Where there is a peat bed still remaining near the sea or only recently washed away, and where peat is continually dug up or drifted in-shore after storms, the peat existing in beds below the level of high water, there is probability of subsidence having taken place. Sometimes the evidence is even more distinct. A general subsidence seems to be going on in those parts of warm seas where the great works of the coral animal are in process of construction. [CORAL ISLAND.]

Subsidy (Lat. subsidium, *an aid*). This term was anciently used to express extraordinary grants to the king, made by authority of parliament. They were very various in character and amount, and were originally levied on the personal estates of those liable to them. Sometimes they were in quantity on all goods, as a tenth, a fifteenth, a thirtieth, the assessment being made by commissioners sworn to execute their office fairly. An ancient example of two such subsidies is to be found in the taxation of the town of Colchester, in the years 1296 and 1301, printed in the Rolls of Parliament. Sometimes they were levied on certain kinds of goods only, as the ninth sheaf, the ninth lamb, the ninth fleece. Sometimes the tax was expressed in kind. Thus, in 1340, parliament granted the king 30,000 sacks of wool as a subsidy for his war against the king of France, and for his recovery of the French crown.

Ultimately, a subsidy came to be considered as a land-tax; tenths and fifteenths being regarded as taxes on personal property, the former on ecclesiastical, the latter on secular, revenues. In the time of Coke a subsidy was reckoned at 70,000*l.*; tenths and fifteenths at 20,000*l.*, the former being at the rate of 4*s.* in the pound on land, the latter at 2*s.* 8*d.* on personal estates. During the first thirty years of Elizabeth's reign, however, a subsidy, as may be learnt from the accounts of the Exchequer, amounted to 100,000*l.* The survey on which the rate was levied was made in 32 Hen. VIII.

After the Revolution, the term *subsidy* was gradually disused. It was necessary to provide larger funds than had been granted during the reigns of the Stuarts, and these were supplied by a land-tax, by customs duties, by a hearth and poll tax, and by the excise. (See, for information on the ancient subsidies, Rastall's *Abridgment*; Davenant's *Essay on Ways and Means*; and the chapter on 'Taxes and Constitutions' in Prof. Rogers' work on *Agriculture and Prices in the Middle Ages*.)

Substance. In Logic and Metaphysics, substance is said to be only the collection or *synthesis* of attributes. 'Attributes,' says Fichte, 'synthetically united, give substance; substance analysed gives attributes.' But in the view of other philosophers, although we can only know substance through attributes, it has nevertheless a real and independent existence; it is 'that unknown, unknowable

substance on which rests all that we experience of the external world.'

Substantive or **Noun Substantive.** In Grammar, that part of speech which denotes a *substance* or *subject*, as distinguished from an *attribute* or *predicate*. [GRAMMAR.]

Substantive Colours. Those colours which, in the process of dyeing, remain fixed or permanent without the intervention of other substances; they are opposed to *adjective colours*, which require to be fixed by certain *intermedes*, or substances which have a joint affinity for the colouring matter and the material to be dyed. [DYEING; MORDANT.]

Substitution (Lat. substitutio, from substituo, *I put under anything*). In Algebra, the replacing of a quantity by another or by a function of several others. The substitution is said to be linear when the variables of a given function are replaced by linear functions of a new set of variables. [LINEAR TRANSFORMATIONS.]

SUBSTITUTION. In Chemistry, this term is applied to such results of affinity as are dependent upon the substitution of one or more atoms of a simple or compound body, for the same or a different number of atoms of another body. Thus, in the decomposition of water, which ensues when sodium is thrown into it, an atom of sodium is *substituted for* (or replaces) an atom of hydrogen, the latter being expelled. These changes are clearly shown by the aid of formulæ. Thus, in the above case,

$$H_2\,O_2 \text{ becomes } H\,Na\,O_2.$$

Another illustrative case of substitution occurs in the conversion of acetic into trichloracetic acid, in which 3 atoms of hydrogen belonging to the acetic acid are substituted by 3 atoms of chlorine:

$$\underbrace{C_4\,H_4\,O_4}_{\text{Acetic acid.}} \text{ becoming } \underbrace{C_4\,Cl_3\,HO_4}_{\text{Chloracetic acid.}}$$

SUBSTITUTION. This term is defined by writers on the Civil Law to be the designation of a second, third, or other heir, to enjoy, in default of a former heir, or after him. Taken in this general sense, it includes all those modes of disposition which are expressed in our law by the terms *entail*, *remainder*, &c. This was also the method of creating what in English law is called a *trust*, in civil law a *fidei commissum*, by *substituting* the person intended really to enjoy the property disposed of, or *cestui que trust*, for the nominal owner or trustee. [FIDEI COMMISSUM; TRUST.]

Substitution, Chord of. In Music, a name given to the chords of the ninth major and minor.

Substratum (Lat. *laid under*). A stratum lying under another. The term *subsoil* is generally applied to the matters which intervene between the surface soils and the rocks on which they rest; thus, clay is the common substratum or subsoil of gravel.

Substyle. In Dialling, the straight line formed by the intersection of the face of the dial with the perpendicular plane which passes through the gnomon. [DIAL.]

Subtangent (Lat. sub, and tango, *I touch*). In Geometry, the part of the axis of a curve intercepted between the tangent and the ordinate. The general expression for the subtangent of any curve is $y\frac{dx}{dy}$.

The *polar subtangent* has reference to polar co-ordinates, and denotes the part intercepted between the tangent and the radius vector upon a line through the pole perpendicular to the radius vector. It is given by the expression $\frac{r^2\,d\theta}{dr}$.

Subtense (Lat. subtensus, part. of subtendo, *I stretch under*). A term sometimes used in Trigonometry to denote the chord of an arc. [CHORD.]

Subtraction (Lat. subtraho, *I draw away*). In Arithmetic, the taking of one number or quantity from another in order to find their difference. The operation is precisely the reverse of addition.

SUBTRACTION. In Law, subtraction is the withdrawal or refusal of a due, as of tithes, or the like.

Subtrahend and **Minuend.** In Arithmetic, two terms which are still occasionally used to denote, respectively, the number to be subtracted and the number to be diminished by the operation of subtraction.

Subulicorns (Lat. subula, *an awl*; cornu, *a horn*). The name of a family of Neuropterous insects, including those which have awl-shaped antennæ.

Subulipalps (Lat. subula, and palpus, *a feeler*). The name of a section of Caraboid beetles, including those which have the exterior palps or feelers awl-shaped.

Subursus (Lat. sub, *under*; ursus, *bear*). The term applied by De Blainville to denote the plantigrade mammalian genera *Meles*, *Taxotherium*, *Palæocyon*, *Ailurus*, *Procyon*, *Nasua*, *Arctictis* (*Ictides*), *Cercoleptes*, and *Amphicyon*, which offer many points of affinity to the true bears (*Ursus*). Many of these minor plantigrades, as *Cercoleptes*, depart from the ursine type, and approach in some manner to the prehensile-tailed *Viverridæ*, e.g. *Paradoxurus*, whilst others, as Amphicyon, are more allied to the old Eocene types.

Succedaneum (Lat.). A medicine or remedy substituted for another.

Succession, Apostolical. In Theology, the alleged uninterrupted succession of priests in the church by regular ordination from the Apostles down to the present day. From this position it has been inferred that the clergy so regularly ordained have a commission from God to preach the gospel, administer the sacraments, and guide the church; that through their ministration only the faithful can derive the grace which is communicated by the sacraments. Hence, according to this view, those

sects of Christians which have no regular succession (having seceded from the Roman Church without retaining ministers regularly ordained, or having subsequently interrupted the succession, i.e. almost all Protestant bodies, except the church of England) have, properly speaking, neither church nor sacraments, since they possess no apostolical authority.

This doctrine is admitted to be of great antiquity in the church; but whether it was known in the first century, is still matter of discussion. As to the historical part of the question, the Epistles of Ignatius are much referred to in support of the doctrine. But these epistles do not declare it in express terms; and the genuineness of these writings is still a disputed point.

At the Reformation, this doctrine was almost entirely lost sight of. The church of England does not affirm it in her articles; but some expressions in her offices have been thought to point more or less distinctly towards it. The first school of Anglican divines did not rely on it in their controversy with Puritanism. They rather rested their argument on the fact, that the church had in early times appointed the episcopal government and regular ordination, and that it could not, therefore, be wise or prudent to swerve from it. It was at this point that Hooker took up the subject; but whether he actually held the tenet, has been much controverted. Mr. Keble (Preface to *Hooker*, p. lxxvii) contends that he did; but, at the same time, admits that there is a marked difference between his language and that of the succeeding school of Laud, Hammond, and Leslie. Under that school, it became the rallying-point of high churchmen, and was zealously maintained by the divines of that section of the church down to, and long after, the Revolution. But since that time it ceased to be brought prominently forward in ecclesiastical controversy, until the rise of the theological school commonly known as the Tractarian.

Succession Duty. A tax imposed by the Succession Duty Act, 1853, on every succession to property, whether real or personal (except those chargeable under the Legacy Duty Acts), according to the value and the relation of the successor to the *predecessor* (the person from whom the interest of the successor is derived). The duty varies according to relationship, as follows: 1 per cent. due from lineal issue, or lineal ancestor; 3 per cent. due from brother or sister, or the descendants of such; 5 per cent. due from father or mother's brother or sister, or the descendants of such; 6 per cent. due from grandfather or grandmother's brother or sister, or the descendants of such; 10 per cent. due from stranger. This Act has in effect charged real property devised by will, and property, whether real or personal, comprised in settlements, with a tax corresponding with the duties on legacies. As regards real property, however, the tax is payable not in respect of the value of the fee simple or capital, but in respect only of the value of the interest of the successor, considered as an annuity for his life.

Succession, Law of. All civilised societies, since they recognise the right of private property as opposed to the communism which characterises a ruder polity [VILLAGE SYSTEM], have also, inevitably, recognised the claim of a deceased person's descendants, and ultimately failing these, of his collateral kindred to the property which he has acquired, and of which he was possessed at his death. Later than the right of succession comes the power of devise, a power which appears to be, according to the opinion of most jurists, a creation of positive law. [WILL.] Both the right of succession and the right of devise are sustained partly on natural equity, partly on economical grounds; the former since the proximity of the relations of a deceased person is a fair ground for a preference being shown to them in distributing the deceased person's estate; the latter since the recognition of such a right or rights by the state is a powerful stimulant to saving, it being thoroughly understood that the general community is benefited by the accumulation of capital made by private persons.

The right being conceded, considerable discrepancies occur in the municipal customs of different communities, and even in different regions comprised within the bounds of the same community, these discrepancies arising generally from the rule which distinguishes landed estate from personal property.

The common law of this country gives the whole of a freehold estate of inheritance to the eldest son, ignoring altogether the other sons and daughters of the deceased person. This appears to be the only community in which the rule of primogeniture is carried so far, and the system or principle affects not only the descendants of the person, who is always technically called the ancestor of those who inherit from him, but his collateral relations, in whose succession males are always preferred to female stocks, and the eldest male of the eldest male stock to all others. Thus, all the relations on the father's side, however remote they may be, are preferred to all the relations on the mother's side, however near they are, where the estate succeeded to is freehold descendible according to the common law.

The rules of succession to such estates were, prior to certain changes introduced by a statute of the year 1834, characterised by two other singular and harsh customs. One was that an inheritance never ascended lineally; in other words, a father could not succeed to his son, though a brother, whose link to the deceased person was contained in the common ancestor (the father), could. This rule was derived from a maxim, *hæreditas nunquam ascendit*; and though the law was relaxed so far as to treat the father as a channel for the brother's inheritance, it was not conceived possible to abrogate the feudal rule so entirely

as to acknowledge a right in the father. The origin of the rule was purely feudal. All estates were conferred by grant or livery, i.e. by actual or symbolical delivery of the estate. If the estate came from anyone but the father, it is clear that there could be no claim of any reversion on the part of the father; if it came from him, the grant was an absolute surrender of all reversionary rights, by virtue of a special statute, known as *Quia emptores*, and the son had equally a new fee.

The other rule, for which no satisfactory explanation has been given, was that half blood could not succeed mutually. Thus, if A dies leaving only a half brother on his father's or mother's side, the rule was that the estate would rather escheat to the crown or the lord, than pass to the half brother. Both these rules were revoked by the Act of 1834.

The common law of succession is not, however, universal. The custom of Kent, known by the name of *gavelkind*, divides landed estates equally, and in a case of succession the eldest son must show that land in this county has been disgavelled, in case he claims as *primogenitus*. Sometimes the same custom prevails in certain manors, in which case the younger brothers must prove the custom, in case they claim to hold as coparceners. Again, in some manors there is a custom that the lands should descend to the youngest son. This remarkable rule, most frequently found in towns, or among burgage tenants, is known by the name of *borough English*, and is, without doubt, a Saxon custom which has survived the Norman law.

Again, the succession of the husband to lands held by the wife, or of the wife to lands held by the husband, varies. Sometimes the husband holds all his wife's lands during his life, provided there be living issue born of the marriage. This is called the *curtesy of England*. In gavelkind lands he holds half only, and on condition that he remains a widower. Again, by common law, the wife's dower is a third of her husband's lands and tenements; by gavelkind custom, the half; in copyholds, it varies in amount, and is called *free bench*.

At a period of English legal history which is not very well defined, the common law was declared to accept the doctrine of representation as opposed to that of proximity. If A dies, and leaves two brothers, it was always admitted that the elder had a prior claim to the younger. But it was not clear, in case the elder of his brothers had also died, leaving issue, that this issue, who were said to represent him, had a preferable claim to the younger brother, who was notoriously nearer to him. Thus, for instance, modern historians have sometimes spoken carelessly of the right of Arthur of Brittany, son of Geoffrey, the nearest brother of Richard I., whose father was dead, as compared with the right of John, youngest brother of the same monarch. But it is clear that at that time John's was considered the better right, and that Arthur's claim would never have been put forward, except to further the intrigues of Philip Augustus. In course of time, however, the other opinion gained ground; and perhaps the leading case, which may be considered to have settled the right of representation over proximity, is the decision on the Scottish crown argued and given at Berwick-on-Tweed, in 1292. The question, however, was considered doubtful for long afterwards, and in fact gave rise to the wars between the houses of York and Lancaster. (Dalrymple *On Feuds*, ch. v.)

The custom of primogeniture has been generally condemned by economists, from Adam Smith downwards. The late Mr. M'Culloch, however, was an advocate of the practice, and an ingenious series of arguments in its favour will be found in the notes which this eminent writer has annexed to his edition of Smith's *Wealth of Nations*. The reasonings for and against the custom are very different when it is interpreted on *economical* or on *political* grounds. It may be defensible on the latter, yet wholly incapable of defence on the former.

The rules of succession to personal estate are borrowed almost entirely from the civil code. In the early ages of English history, personal estate was administered generally by the clergy who were attached to the Roman law. In personal estate the rule of equal partition among persons related in equal degrees to the deceased person, with an absolute preference to relations in the ascending or descending line, and without regard to sex or half blood, has always prevailed. In foreign countries, most of which have accepted the civil code, the rule of succession to real is the same as that to personal estate; and, with scarcely any exception, this rule has been accepted in the United States and the British colonies.

It must always be remembered that in the British Isles, as a matter of fact at the present day, the succession to property is usually regulated by the express provisions of SETTLEMENTS and WILLS rather than by the laws of descent or of distribution in case of intestacy.

The question as to the extent of relationship to which the right of succession should attach, has been debated. Bentham long ago urged that when a man died without a will, and without relations nearer than cousins german in the first degree, the estate should revert to the crown. This view of the great jurist was founded not on purely speculative grounds, but on matters of fact of very considerable public interest. The litigation in favour of remote heirs at law, the attempts made on the most frivolous grounds to upset wills, the general custom of paying costs out of estates, whenever there is the slightest pretext for litigation, and the frequent hardship which the impunity given to vexatious opposition involves, are powerful arguments in favour of annihilating these evils by cutting away all

these contingent rights. There seem to be solid grounds for the belief that infinite good would result from the acceptance of Bentham's suggestion, and that it might be applied to titles as well as to estates.

In the Civil Law, and in those modern systems which are derived from it, there is no distinction between movable and immovable property, considered as a subject of succession. Succession, whether of real or personal property, is either *ab intestato* or by testament. The order of succession ab intestato, according to the civil law [DESCENT], is to be found in the laws of Justinian (*Novell.* 118, 127, &c.). It admits three classes of successors—descendants, ascendants, and collaterals, who are preferred in that order in the succession; so that if a man leave any descendants, all ascendants and collaterals are excluded; and ascendants exclude collaterals, except brothers of the whole blood and their children. The children of the deceased partake equally. Stepchildren are strangers to the succession of their step-parents. Children, the issue of several marriages, succeed equally to the property of their father; but severally to the property of their respective mothers. Grandchildren take *per stirpes*, or by right of representation; i. e. if a child die in the parent's lifetime, his children divide his share equally. Among descendants, he or she of the nearest degree is preferred, and there is no right of representation. Brothers and brothers' children per stirpes divide with parents; but it is doubtful whether more distant ascendants divide with them, or not. Succession among collaterals is said not to extend beyond the tenth degree. The wife (by *Novell.* 53, c. 6) succeeds, under certain circumstances, to a fourth.

Succession, War of the. In Modern European History, two wars, in which great part of the Continent was involved, are commonly known by this name: 1. That of the Spanish succession, occasioned by the dispute whether the succession of Spain should devolve on an Austrian or a French prince (1702–1713); terminated by the peace of Utrecht, which placed the house of Bourbon on the Spanish throne. 2. That of the Austrian succession, in which the right of Charles VI., emperor of Germany, to settle his Austrian dominions on his daughter Maria Theresa, was contested by France, Prussia, Bavaria, and other states; terminated by the peace of Aix-la-Chapelle, 1748.

Succinea (Lat. succinum, *amber*). A genus of fresh-water Gasteropods, so called from the transparent texture and amber colour of the shell. Of this genus, two species (*Succinea amphibia*, Drap., and *S. oblonga*) are British, and are found occasionally in the river Wandle, and in Greenwich marshes.

Succinic Acid (Lat. succinum). An acid obtained among the products of the destructive distillation of amber; when pure, it is a white crystalline substance. Its salts are termed *succinates*; of these the *succinate of ammonia* is occasionally used as a test for iron. It precipitates the peroxide of that metal in the form of a brown insoluble succinate.

Succinite (Lat. succinum). An amber-coloured variety of Lime Garnet [TOPAZOLITE] found in small, rounded, translucent masses, in a serpentine rock in the Viss Valley, Piedmont.

Succory. The *Cichorium Intybus* or *Wild Endive*, called also *Chicory*. The root of this plant, which resembles a carrot, when cut into slices, dried, roasted, and ground into powder, is used for the adulteration of ground coffee. It has a somewhat burnt flavour, slightly resembling that of coffee, but it yields a large quantity of a rich brown infusion, or decoction, with water. To detect the adulteration, sprinkle the suspected article upon the surface of some water in a jar or tumbler: if genuine coffee, it remains for a long time floating, scarcely tinging the water, and appearing greasy or not easily wetted; whereas, if succory powder be present, it communicates a deep reddish-brown tint to the water, and portions of it soon sink to the bottom. [CICHORIUM.]

In order to check the adulteration of coffee by chicory, a Treasury minute of 1852 prohibited the sale of coffee mixed with this material, unless parcels were labelled to the effect that such a mixture had been made. But as chicory was liable to no duty, while coffee was liable, the regulation was ineffectual, and the adulteration was general; and as far as regards coffee supplied in the form of infusion, it was chiefly made of chicory. The legitimate remedy would have been an excise duty levied on chicory, which should be equal in amount to that levied on coffee. This remedy was applied in part in 1860. The duty was raised in 1861, again in 1862 and 1863, and finally settled in 1864 at 24*s.* 3*d.* the cwt.

The flavouring and colouring matter of chicory is wholly destitute of the peculiar properties of coffee; it is, in fact, little else than caramel suspended in woody fibre.

Succubi (Lat.). During the middle ages, this term was used to denote the female devils with which wizards were supposed to have intercourse, in contradistinction to the incubi, or male devils, to whom it was stated that the witches submitted themselves. By the Scotch Highlanders, the succubi are known as the Leannain Lith. (Kirk, *Secret Commonwealth*, 1691.) Lilith, the first wife of Adam, according to the Rabbinical tradition, was regarded as their queen. From her name the word *lullaby* (Lili Abi) is by some supposed to be derived; but this is very doubtful. (Lecky, *History of Rationalism*, ch. i.)

Succursal. In Ecclesiastical usage in various Continental countries, a church established by way of *succour* to a parochial church, regarded as insufficient for the wants of its community: answering to the English *chapel-of-ease.*

Sucker. In Botany, a branch or shoot thrown up by a plant from beneath the surface of the ground, as is common with roses, &c. [PROPAGATION OF PLANTS.]

Sucking Fish. The fish so called is rather a *sticking fish*, since it attaches itself to other fishes, or to the bottoms of vessels, for protection or conveyance, not for drawing anything therefrom by the act of suction. The fish is recognised by the flat oval adhesive disc on the top of the head. It is a comparatively small species, of the *subbrachial division of the Malacopterygians*, in the Cuvierian system; it was called REMORA by the ancients, in reference to its influence—exaggerated in their narrations—in retarding the course of the vessel to which it had attached itself: it is the *Echeneis Remora* of Linnæus.

Sucking Pump. A pump which raises water by exhausting the air from the barrel, and into which vacuous space the water is forced by the pressure of the atmosphere upon the exposed surface of the water. Theoretically, the suction or sucking pump would raise water through a height of 30 feet or a little more, but it is customary (in order to allow for defects of workmanship, &c.) to reckon that the effective height to which water can be raised in this manner is at the most 24 to 26 feet.

Sucrose. A generic name for those sugars which, though identical in composition and properties, are obtained from sources different from that of cane sugar. It includes the sugars of the cane, beet, turnip, carrot, maple, birch, palm, Indian corn, and others less generally known.

Suctorians (Lat. sugo, *I suck*). The name of a tribe of Cartilaginous fishes, comprehending those which, like the lamprey, have a circular mouth adapted for suction.

Sudder (Hin. sadr, *eminence*, *chief*, &c.). A term applied in British India in various significations, but, principally, to the courts of Sudder Adawlut, which were those of highest civil and criminal jurisdiction in all the presidencies, until amalgamated by recent law with the high courts in some of those divisions. A Sudder Ameen is a superior native civil judge or arbitrator, having a jurisdiction previously limited in different localities.

Sudoriparous Glands (Lat. sudor, *sweat*; pario, *I produce*). In Anatomy, the secreting organs of the sweat, which consist of a slender elongated blind glandular tube, coiled into a lobular form and embedded in the subcutaneous fat, and continued thence in a spiral course to the cuticle, where it opens by an oblique pore.

Sudra. [CASTE.]

Suet. The fat situated about the loins and kidneys, which is harder and less fusible than that from other parts of the same animal. That of the ox and sheep is chiefly used; and when melted out of its containing membranes it forms tallow, and is largely used in the manufacture of candles and the ordinary soaps. Beef and mutton suet, when fused, concrete at a temperature of about 100°. Like other kinds of fat, it is a compound of carbon, oxygen, and hydrogen.

Suez Canal. The construction of a canal across the isthmus of Suez, which should connect the Mediterranean with the Red Sea, is a scheme which in one form or other has attracted the attention of governments and private speculators from time immemorial. Nature seems to lend itself to the practical execution of such a canal, for the isthmus is a depression, and a considerable part of the soil is below the level of the two seas. In the time of the ancient Egyptian kings, a canal was constructed, extending from the Nile, near Belbeis, to the gulf of Suez; but this was only for boats, and did not last long. The only serviceable plan seems to be a ship canal from Port Said to the gulf of Suez, a distance of 90 miles. Early in 1856, a concession was granted to M. de Lesseps to construct: 1. A ship canal from sea to sea, 330 feet wide, and sunk 20 feet below the Mediterranean; 2. A canal to the Nile, available for irrigation as well as traffic; 3. Branches for irrigation. The company was constituted in 1859; and considerable progress has now (1866) been made in the execution of the work.

There are three depressions in the line of the proposed canal, one near the Mediterranean, another (Lake Temseh) half-way across, and the third (the Bitter Lakes) a long depression near Suez, which appears in former times to have been the site of a canal. Except two small ridges, one 30, the other 45 feet above the sea, the rest of the line of the projected canal is only 5 to 8 feet above the waters of the Mediterranean. The difference of level between the Red Sea and the Mediterranean is only about 18 feet.

Up to the close of 1865, about four millions and a half sterling had been expended on the works; less than half that sum, however, representing the cost of labour for excavation. The canal had at that time been cut so as to admit the passage of water for most part of the way; but the whole had to be deepened, except where the deep lakes intervene. This work involves the removal of about 60,000,000 cubic mètres of sand and rock, and presents great difficulties. The work of the central part of the canal, near the ridges of Serapium, was about half done. The ports and harbours at the extremities of the canal had hardly been commenced. The original dimensions proposed seem to be no longer adhered to, the width of the part in progress being 58 mètres and the depth 8 mètres. There are very large and costly engineering works still to be executed, and, in fact, the real difficulties seem only now beginning. There does not appear, however, to be any insuperable difficulty in the way of final success, if money can be obtained, and upwards of seven millions sterling of the nominal capital of the company is still available.

Sufferance, Tenancy at or by. In Law, the least or lowest estate which can subsist in

real property; in strictness, a possession only; which arises when a person whose lawful right to occupy has ceased, continues to do so without the agreement or disagreement of the person in whom the right of possession resides.

Suffetes (said to be from the Phœnic. schopetim). Carthaginian magistrates, whose office much resembled that of the Spartan kings and Roman consuls. Their number was two, and they were elected annually from the noblest families of the state. The functions of the suffetes seem to have been confined chiefly to the management of civil affairs. Thus, it was their province to assemble the senate and preside in it, and also to propose the subjects of debate, and collect the votes; but there are instances recorded of suffetes leading the armies of their country. All the cities of note in the Carthaginian dominions had likewise their suffetes; but these, of course, were invested merely with municipal authority. (*Mém. de l'Acad. des Inscr.* vols. xxxiv. xxxviii.; Arnold, *History of Rome*, ch. xxxix.)

Suffragan (Lat. suffragium, *a vote*). In Ecclesiastical usage, every bishop is said to be suffragan, relatively to the archbishop of his province; thus the bishop of Carlisle is suffragan to the archbishop of York, &c. either on account of the suffrages given by them in the provincial synods, or because they cannot be consecrated without the *suffrage* or consent of the archbishop. Titular bishops, ordained to assist a bishop in his spiritual functions, are also commonly, but rather improperly, styled *suffragans*; a title adopted by the stat. 26 Hen. VIII. c. 14, which named twenty-five places for which such suffragans might be appointed. This Act was repealed by 1 & 2 Philip & Mary c. 8, but was revived by 1 Eliz., in whose reign we find notices of suffragans at Dover, Hull, and elsewhere. This law, which has not been acted on for upwards of two centuries, is still unrepealed. [CHOREPISCOPI.]

Suffrage (Lat. suffragium). In all communities which are not governed despotically, and which possess an administration, the assent of the people either in whole or part is invited, either to the election of magistrates, senators, legislators, and the like, or to the passing of laws, or both. This was the case with the ancient states of Greece and Rome, and the Tyrian colonies in so far as we are acquainted with their constitution. At Athens, the freest state of antiquity, the whole free native population was invited to elect magistrates, to pass laws, and even to decide party contests by the singular machinery of OSTRACISM. At Sparta, the institutions of which were rigid and unyielding, the assembly of the Spartans, who alone were possessed of political rights, elected the annual officers, called EPHORI, who gradually appropriated the chief part of the administration. Even when the constitution was aristocratic, the electoral power remained with the people, though the franchise was limited and the opportunity for exercising it still more so. In Rome, the suffrage was more complicated, and as its machinery is not exactly described by those who lived while it operated, its distribution is more obscure. But the people elected magistrates and passed laws. Those who had been elected were, as a matter of course, drafted into the senate, this body having, in certain directions and on certain occasions, a legislative power. Similar or analogous arrangements are made in the Italian republics.

The electoral franchise in the larger states of the modern world is reputed to have been derived from the councils of the church and the election of ecclesiastical officers. There seems little doubt that, in the early history of Christian communities, the election of officers was in the hands of the mass of believers. Persecuted and poor, forced to perform their rites in secret, and liable perpetually to charges of treason, the early Christians were driven to establish equality in the community; and when the church was acknowledged by the empire, the form at least of an election remained. In the councils the process was even more enduring; and as the clergy met in order to enforce discipline, and occasionally to aid the exigencies of the sovereign, the developement of a parliamentary system was effected long before a similar method was adopted for the laity. Forms of election, suffrages given on important matters of domestic economy, were familiar in the manor courts, and when the suffrage was given, it was no novelty in fact, though its immediate purpose was a novelty by no means agreeable to the recipients. (See a somewhat imaginative scene in Palgrave's *Merchant and Friar*, in which a mediæval election is described.)

It is not easy to determine on what persons the suffrage was conferred in the earliest times. In all likelihood, as the election of knights and burgesses was simply that they might make grants to the crown, and be in consequence permitted to petition for redress of grievances, all who were liable to taxation would be electors. For instance, the number of persons assessed to the tax in the borough of Colchester, in the year 1301, is 391. There is, probably, no reason to doubt that each and all of these persons (in pursuance of the terms of the great charter, that no freeman should be taxed without his consent) were empowered to register votes for any candidate whom they might think proper to elect, and to whom they might pay the modest wages of parliamentary attendance.

Towards the close of the fourteenth century, the representative in parliament, and especially the knight of the shire, became a far more important personage than he was at the first institution of parliament. Hence a seat in the House of Commons became an object of ambition, and no small value was attached to the franchise. In order, it seems, to put a stop to undue returns by the sheriff, a declaratory statute was passed (8 Hen. IV.) Dec. 1406,

by which, notice having been given fifteen days previous to the day of election, the 'suitors at the county court' were invested with the suffrage. Who these suitors were, has been much debated, but on the whole it seems likely that all possessors of estates of inheritance were included in the term. In the year 1430, however, the Commons petition, that whereas 'knights of the shire had of late been chosen by outrageous and excessive numbers of people and of small substance, who crowded tumultuously to county elections,' it would be desirable to limit the suffrage to holders in free tenements of the annual value of forty shillings. There is no doubt that this limitation of the county franchise was reactionary, but it does not appear that any similar limitation was put on the boroughs.

A variety of customs crept up in these boroughs, and the suffrage was very differently awarded. In some it was confined to the corporation, in most to the freemen; or it was extended to all residents paying scot and lot, i.e. local taxes. In some, as at Preston, it was universal.

These anomalies were remedied by the Act of 1832, commonly called the Reform Bill. As a rule, the potwallers or potwallopers, i.e. those who had any habitation in the borough, or, in the homely meaning of the word, boiled a pot in it, were extinguished. The freemen were retained, but could exercise their franchise only if they resided within a few miles of the borough, while the rental qualification of 10*l.* per annum, with certain conditions intended to obviate the sudden creation of voters, and securing the payment of local taxes, was created. In the counties, the freeholders were supplemented by copyholders possessing a certain amount of clear annual value, and by occupiers to the amount of 50*l.* and upwards, the last being inserted on the electoral roll by the so-called Chandos Clause.

Of late years, many projects have been put forward for an extension of the suffrage, some being the demands of parties outside parliament, some being government bills. All have hitherto failed. The 'Chartists' represented twenty years ago the principle of universal suffrage, but their organisation broke down, and is only now reviving under another form. The latest suggestion made by an administration was that of the Russell-Gladstone cabinet, which proposed 14*l.* for the counties and a 7*l.* rental for the boroughs. The House of Commons, however, substituted a rating for a rental clause, on the motion of Lord Dunkellin, and the government resigned. It appears, however, to be agreed on all hands, that the settlement of the question is only temporarily postponed, and that some decision must be speedily arrived at which shall, if possible, be final. [Reform; Representation.]

Suffrago (Lat. suffrago, *the pastern*). In Mammalogy and Ornithology, the joint of the tibia with the tarsus.

Suffruticose (Lat. sub; frutex, *a shrub*). In Botany, this term is applied to any plant which is not exactly either a shrub or an herbaceous plant; i.e. which has not hard woody twigs and complete buds like the one, nor perishable succulent twigs like the other. Lavender is an instance of a suffruticose plant.

Sufi. [Sofi.]

Sugar (Fr. sucre, Ger. zucker). A crystallised substance, obtained in greatest plenty from certain varieties of tropical grasses, but present to some extent in all grasses, and found in an infinite variety of other plants. The specific characteristic of all sugars is that they contain carbon, hydrogen, and oxygen only, and in definite proportions. One kind of sugar only is fermentable, this being called *glucose* or *grape sugar*. Some other kinds, as cane sugar and sugar of milk, may by particular processes be turned into glucose, and be made by means of one fermenting process to yield alcohol, and by another and subsequent process vinegar. [Acer; Beet; Saccharum.]

In his *History of Sugar and Sugar-yielding Plants*, Mr. Reed states that the sugar cane was first made known in the West by the conquests of Alexander the Great; Nearchus, the admiral sent down the Indus, describing it as a kind of honey growing in canes or reeds. From India the sugar cane was introduced into Arabia, Egypt, and the western parts of Asia. Dioscorides, in the first century of the Christian era, is said to be the first writer who uses the word *saccharum*, or sugar, a word which may be identified with the Sanscrit çarkara, and perhaps the Hebrew shakar and the Malay jagara. The Greek term is σάκχαρ. Pliny remarks that sugar in his time was used for medicine only. In the seventh century, the physician Paulus Ægineta describes sugar as the Indian salt, and recommends that a piece be kept in the mouth during fevers. The sugar cane was known in the Morea, Rhodes, Malta, and Syria, before the time of the Crusades; and there is evidence that it was introduced into Sicily between 1060 and 1090. It was brought into Spain by the Moors, on their conquest of the country early in the eighth century; and a large amount of sugar is still manufactured in the tract which lies between the Sierra Nevada and the sea; the chief seat of the manufacture being at Almuñecar. In the beginning of the fourteenth century, sugar, according to Sanuto, was supplied from Sicily, Cyprus, Crete, Malta, and Alexandria. That of Cyprus and Alexandria was the cheapest, but it was always exceedingly dear. The price of sugar bought at this period in England was on an average 1*s.* 4½*d.* the pound troy. (Prof. Rogers, *On Agriculture and Prices in England*.) Sugar continued long to be the choice luxury of the rich.

In 1506, sugar was introduced into the Canary Islands, and thence was taken to the islands of the Mexican Gulf. It has become in an eminent degree the produce of the intertropical regions of the New World, though the production of this necessary of life is increasing in some parts of India and the islands of the

Indian seas. It has been prepared from time immemorial in China; but, cheap as labour is in that fertile and populous region, the Chinese do not seem able to compete with the more favourable climate and the greater mechanical appliances and skill possessed by the sugar planters of the Leeward Islands and Brazil.

According to some, the sugar cane is indigenous in America and the West Indies; while others maintain that it was not known until transplanted thither by Europeans. In Hispaniola, according to Peter Martyr, the sugar cane was known in 1493: it was introduced into Madeira from Sicily in 1420. In 1641, sugar canes were transplanted from Brazil to Barbadoes, but the sugar there made was at first so bad as to be scarcely worth exporting. By 1676, however, the manufacture had been so far improved and the trade had so increased as to employ 400 vessels, averaging 150 tons burden.

The first account of a shipment of sugar to England, is apparently one from Venice, of 100,000 lbs., in 1319, and during the two succeeding centuries it was imported in small quantities, but chiefly for medicinal purposes. In 1653, Hawkins, the navigator, brought sugar to England from St. Domingo; but it came into general demand only on the introduction of tea and coffee.

The process, as carried on in our West India islands, consists in pressing out the juice by rolling mills, and carefully evaporating it till it has acquired the proper consistency for crystallising; lime water is added during this operation, to neutralise any free acid, and to facilitate the separation of certain vegetable matters, which, in consequence of the action of the lime, rise more readily to the surface, and admit of being skimmed off. When duly concentrated, the syrup is run off into shallow wooden coolers, where it concretes; it is then put into barrels with holes in the bottom, through which a quantity of treacle or molasses gradually drips, and the remaining sugar acquires the granular crystalline state; it is packed into hogsheads, and comes to us under the name of *raw* or muscovado sugar. [SUGAR REFINING.]

The chemical characters of sugar are well defined, especially those of the crystallisable or cane sugar. Its specific gravity is about 1 6. It dissolves in all proportions in water, is less soluble in alcohol, and is recognised by its purely sweet taste. It is blackened by sulphuric acid; and when about one part of this acid is added to two of thick syrup, the mixture presently boils up into a black frothy mass, which is little else than carbon, acid, and water. In respect to ultimate composition, sugar belongs to that important class of proximate vegetable principles which are theoretically regarded as compounds of carbon and water; i. e. of carbon and oxygen and hydrogen, in the same relative proportions as they exist in water. The following shows the results of numerous analyses of the finest loaf sugar in a dry and pure state, with its atomic constitution:—

	Atoms	Theory	Expt.
Carbon	24	42·11	42·85
Hydrogen	22	6·43	6·35
Oxygen	22	51·46	50·80
	68	100·00	100·00

Several other varieties of sugar have been chemically examined; such as grape sugar, honey sugar, mushroom sugar, manna, liquorice sugar, &c.

Total Imports of Refined Sugar and Sugar Candy,

	1860	1861	1862	1863	1864
Unrefined and refined sugar and sugar candy from all parts	cwt. 344,089 9,140,198	cwt. 241,795 10,620,859	cwt. 321,409 10,181,257	cwt. 296,676 10,999,361	cwt. 925,694 11,605,882

Statement showing the Net Revenue, and the Average Price, inclusive and exclusive of Duty, from 1860 *to* 1864 *inclusive.*

Years	Net Revenue	Average Rate of Duty			Average Price per Cwt. in Bond			Average Price per Cwt. inclusive of Duty		
	£	£	s.	d.	£	s.	d.	£	s.	d.
1860	5,833,484	0	13	4	1	7	2	2	0	6
1861	6,104,325	0	13	4	1	5	8	1	17	0
1862	6,215,346	0	13	4	1	5	0	1	18	6
1863	6,249,815	0	13	4	1	5	2	2	0	9
1864	5,157,083	0	11	1	1	6	3	1	19	4

The diminution of the revenue in 1864, as compared with the years immediately preceding, is owing to the reduced rates of duty which took effect in that year.

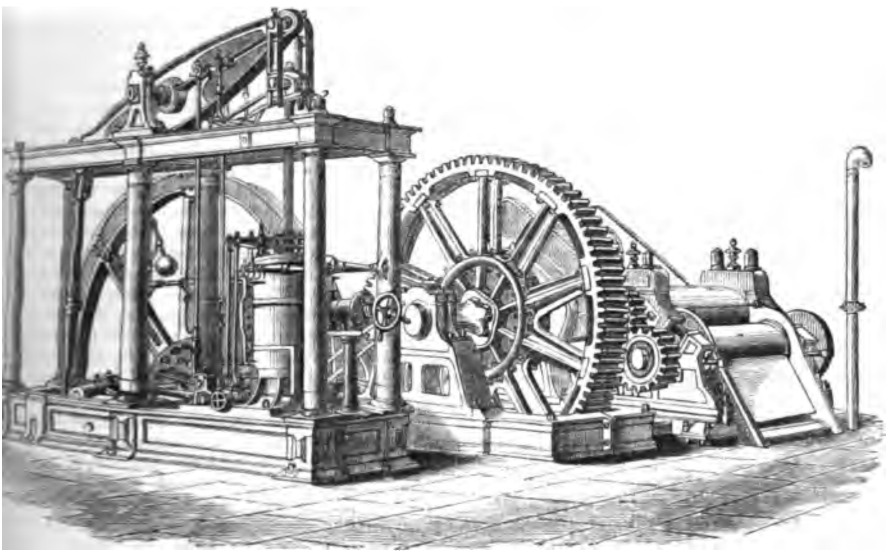
Sugar Candy. Sugar clarified, and rendered transparent by crystallisation.

Sugar Cane. [SACCHARUM.]

Sugar Mill. A mill for expressing the juice from sugar canes, consisting usually of three horizontal iron rollers, two of which are set on the same horizontal plane, while the third is set over and between the other two, so as to touch both. The canes are fed in between the top roller and one of the lower ones, and there receive the first squeeze. The juice runs down into a trough formed in the base of the mill; and the canes travel on and receive their second squeeze between the top roller and the second horizontal one, after which, the juice being all squeezed out, the residual woolly fibre, known as *begass*, is used as fuel beneath the boiler of the engine that drives the mill. An approved form of sugar mill, with bêam engine for driving it, is shown in the annexed figure. Such mills are now made of very large size, and the most material condition of their efficiency is great strength in the working parts, so as to obviate as far as possible the risk of injury or stoppage even when subjected to the rough usage to which these mills are exposed. A friction coupling, set in some convenient part of the mill, between the fly-wheel and the rollers, would be a useful expedient, as it could be screwed up so as to transmit the motion of the engine

when the mill was in the ordinary course of working, but yet to slip when accidentally subjected to very severe strains.

An engine of 20 horse-power will work a *sugar mill* having rollers 5 feet long and 28 inches diameter, the rollers making $2\frac{1}{2}$ turns per minute. An engine of 18 horse-power will work a mill with rollers $4\frac{1}{2}$ feet long and 26 inches diameter, and an engine of 16 horse-power a mill with rollers 3 feet 8 inches long. Twelve horse-power will work a mill of which the rollers are 4 feet 2 inches long and 24 inches diameter, and 10 horse-power a mill with rollers 3 feet 10 inches long and 23 inches diameter. It will require an engine of 25 to 30 horse-power to drive a mill with rollers $5\frac{1}{2}$ feet long, 30 inches diameter, and making $2\frac{1}{4}$ turns per minute. Such a mill will express the juice out of 130 tons of canes in from 12 to 15 hours. An acre of land produces from 10 to 20 tons of canes, according to the locality and the age of the canes. The juice expressed from the canes will stand at from 1·8° to 12° of the saccharometer, according to the locality and other circumstances. The weight of sugar produced



Sugar Mill.

varies from 6 to 10 per cent. of the weight of the canes. Well-constructed mills give in juice from 60 to 70 per cent. of the weight of the canes; and in no case should the surface of the rollers move at a greater speed than 16 feet per second, else the necessary *time* for the expression of the juice will not be afforded, and a much less per-centage in proportion to the weight of the canes passed through will be obtained. At one time, sugar mills with vertical rollers were much employed, and motion was given to them by a pole, the end of which was moved round by a horse in a circular path. But the difficulty of feeding such rollers evenly with canes was so great as to cause the general abandonment of that species of mill. The framing of sugar mills is generally made of cast iron, and the rollers are of cast iron, but the spindles on which they turn are of wrought iron.

Sugar Refining. The series of operations by which white or refined sugar is produced from brown or raw sugar. The cane juice, after having been expressed by the sugar mill, is conducted into a caldron or clarifier holding from 300 to 400 gallons, where it is heated, and a scum is thrown up and removed, after which the liquor is evaporated to the consistency of syrup in a series of evaporating pans, of which the last is called the *teache*. When the syrup is sufficiently concentrated, it is poured into square wooden boxes, where it sets, and is then placed in hogsheads perforated at the bottom to enable the molasses to drain out. The sugar thus obtained is raw sugar, and on its arrival in this country it is dissolved in water heated by steam, filtered through bag filters to remove all refuse, and then passed through a deep stratum of animal charcoal, not reduced to dust, but granulated like coarse gunpowder. The charcoal takes away a large part of the colour of the syrup, and leaves it almost colourless. The syrup is then evaporated in a pan called a *vacuum pan*, which consists of a pan or vessel, generally of copper, heated by a convolution of steam pipes placed within it, and fitted with an air-tight cover: a vacuum being maintained within the pan by condensing the steam as it is raised from the syrup by the action of the heated coil. This condensation is effected by means of a jet of water in

a contiguous vessel, into which a pipe from the pan opens. The water so introduced is pumped away by an air pump, or, as it is called, a *vacuum pump* (resembling in all respects the air pump used in steam engines), the existence of the vacuum being thus constantly maintained. Boiling in vacuo has the effect of enabling the vaporisation to be carried on at a lower temperature, and therefore with less carbonisation of the sugar than would otherwise take place. When the syrup has been boiled sufficiently for granulation to take place, a plug is pulled out in the top of the pan to enable air to enter, and by opening a cock in the bottom of the pan the syrup is drawn off into a vessel beneath, whence it is ladled into conical moulds, open at the base and with a small hole at the apex which so long as the sugar is liquid is kept stopped up. When the sugar is set, the small orifice at the apex of the mould is opened, and a mixture of sugar and water is poured over the base of the cone, which is kept uppermost, while the apex is suffered to drip into a vessel placed beneath. The water in the syrup penetrates through the mass, and washes away any treacle or colouring matter which may remain in the mass; for it is the property of this colouring matter to spread itself over the surface of the crystals, but not to enter into their composition, and it may consequently be, for the most part, washed away by water suitably applied. Dark brown sugar spread upon a frame of wire gauze, beneath which a vacuum is maintained, is rapidly whitened if sprinkled with water out of the rose of a watering pot, the treacle being carried away with the water. Molasses, as it arrives in this country from abroad, generally contains a good deal of sugar, which is extracted by boiling the molasses and emptying it into moulds, when the treacle drips away, leaving within the mould a coarse brown sugar, which is again dissolved, passed through charcoal, and crystallised in the manner already described.

In refining sugar, the sugar should be turned out with a large grain. This end is promoted by bringing the liquor first introduced into the pan to the crystallising point. Instead of emptying it and taking in a new supply, this liquor is retained in the pan, new supplies being from time to time added as the water is evaporated, so as to keep the pan constantly full. By this method, the crystals first formed in the pan become nuclei about which the particles of sugar subsequenlty added may arrange themselves, and as there are thus fewer crystals each of them is larger. It is usual to allow the temperature of the pan to rise just before the liquid sugar is run out, by partially turning off the injection. Any very small crystals are thus dissolved, and instead of forming themselves anew the particles go to increase the size of the larger crystals. In former times, blood was used in sugar refining, but its employment has now been long discontinued.

The action of animal charcoal in bleaching syrups and other liquids is not well understood; but it appears to be owing to the presence of the charcoal in the bones deoxidising the phosphates and other substances which enter into their composition; these substances again slowly oxidise by contact with the liquid, from which they take oxygen, leaving the equivalent of hydrogen in the nascent state, which combines with the free charcoal or colouring matter of the liquid, forming with it a colourless compound. The charcoal filters employed in sugar houses are often 20 feet deep or more. After a certain period of use, the charcoal loses its bleaching power. It must then be removed from the filters, and reburnt, when the bleaching power is restored; but after several repetitions of this process this power is lost altogether. Latterly, centrifugal machines for drying the sugar have been introduced in sugar refining. These consist of cylinders of wire gauze, which are put into rapid rotation, and the wet sugar being placed in these cylinders the liquid is ejected at the circumference by the centrifugal force. In some places abroad the sugar is refined at the same time that it is made. To defecate 330 gallons of juice, 6 boiling pans or clarifiers, 4 scum presses, and 10 filters are needed; and to granulate the sugar, two vacuum pans are required, 6½ feet in diameter, with two condensers, and it is better to have also two air-pumps. Three cylindrical boilers of 6 feet diameter will generate the steam required to boil the liquor in the vacuum pans; and 10 centrifugal machines, driven by a 12-horse engine, which will also drive a pair of crushing rollers, will be requisite to whiten the sugar by wetting it and again drying it by centrifugal force. The three modern improvements in sugar refining are: the vacuum pan, which diminishes carbonisation; the use of animal charcoal for bleaching; and the centrifugal machine.

Suicide or **Self-murder** (a word coined from Lat. sui, *self*, and cædo, *to kill*). Few chapters in the history of the human mind are more singular than that of suicide, as showing the kind of honour and estimation which a practice so unnatural has attained in the feelings of many nations. The rank which religious suicide has held from immemorial antiquity, and still holds, in the opinion of the Hindus, has been too often described, and is too familiar in its most notorious and painful instances, to need more than adverting to on the present occasion. It is said that the practice is condemned by their older books; if so, the traditionary sentiments of the people have been formed on some different model. The suicides of the Hindus have proceeded partly from fanaticism, partly from an apathetic philosophy, those of the ancient Scandinavians, esteemed equally honourable, from the temper of warriors, who could endure any evil except the approach of helpless and unwarlike old age.

Among the Greeks, the first enquirers who reasoned out the principles of human life and action by a train of philosophical investigation, singularly vague and discrepant opinions on this subject seem to have prevailed. Socrates, the great master of ethics, was emphatic in his condemnation of suicide. Plato speaks in a more dubious strain. Writing as a lawgiver, he reprobates it; and in his arguments on the subject is to be found the well-known illustration which has figured ever since in all such discussions, in which he compares it to the desertion by a soldier of his post; yet he expressly excepts from his censure those cases in which it is committed under the pressure of immitigable calamity. Pythagoras, at an earlier period, denied its lawfulness. (*Athenæus*, l. iv.) In the later days of Greek philosophy, both Stoics and Epicureans found arguments for its defence in their respective principles. The former sect was notorious for its tenets on this subject; Zeno and Cleanthes, its great masters, having both put an end to their own lives, as Democritus had done before them, from the mere tedium of old age.

> Cum jam matura vetustas
> Admonuit memorem motus languescere mentis,
> Sponte suâ letho caput obvius obtulit ipse.

The argument of an Epicurean philosopher on the topic may be collected from Cic. *Tusc. Disp.* v. 41; and, indeed, may be compressed in the pithy Greek motto for a drinking party, Ἢ πῖθι, ἢ ἄπιθι—*drink, or begone.* The influence of Greek philosophy had, as is well known, a great share in producing that tendency to suicide which distinguished the higher society of Rome in the later days of the commonwealth. The 'Roman death,' as it is emphatically called, was not really a national habit; the older manners of the commonwealth repudiated it; its prevalence was owing to foreign doctrines, acting on minds affected by the violent passions, engrossing luxuries, and rapid vicissitudes of fortune which distinguished that era. Virgil returns to the Pythagorean view; and, without inveighing against suicide, represents it as a sad and mournful death, the perpetrators of which are doomed to a long and shadowy existence—without torment, but without enjoyment; one which they would willingly exchange for the bitterest poverty and labour in the cheerful light of day. At a later period, suicide committed by criminals under accusation was made criminal by the Roman law. This was with a view to preserve the forfeiture of the criminal's property to the government. Suicide, as such, does not seem to have been the subject of legislation.

Although Christianity was not slow in effecting a reform in the feelings of mankind on this subject, yet some relics of the ancient sentiments lingered awhile, even in the minds of enlightened believers. The fanatical Donatists were greatly addicted to suicide, and are justly condemned on this account among others by the early writers of the church, who considered suicide lawful only when committed by virgins to preserve their chastity. The cherished sentiments of the fathers of the church on this subject rendered them lenient to such victims of honour, and some of them have even gone so far as to commend them. Augustine only pities them, and expressly classes all suicide as homicide. (*De Civ. Dei*, l. i. c. 19.)

Among the writings of later thinkers, the reasonings urged by Rousseau against suicide in the *Nouvelle Héloïse* are well known. Though there is little convincing in his logic, yet the side he takes is made to appear the generous and noble one; and in this case Rousseau must be owned to have done service to the cause of morality. Madame de Staël, in her *Essay on the Influence of the Passions*, advanced a sort of defence of suicide; in her later work (*Réflexions sur le Suicide*, published in 1810) she has enforced the more customary doctrine with much eloquence and feeling.

In discussions on the subject of proneness to suicide in particular classes or nations, it is impossible to disconnect it from that of insanity; because the miserable delusions of that disease constantly impel their victim to its commission. In societies, therefore, where insanity is most common, the number of suicides will be greatest. The tendency to deliberate suicide has been almost epidemic in many communities. Nor does it arise from similar causes, or in similar states of society. It prevails sometimes in effeminate communities, where there is little zest or excitement in life, with mean habits, little self-respect, and much apathy: thus, it is extremely common in China, even, it is said, among the lower classes, notwithstanding the proclamations, full of ethical saws, which the magistrates issue against its commission. Among people of minds thus disposed, the act is generally deliberate, and unconnected with insanity; so, again, where it results from a cold temperament, and a sarcastic and contemptuous view of life, which was the notion formerly entertained by foreigners of the English mania for suicide; a notion which probably had not much foundation in truth at any time. Sixty years ago, Mercier (*Tableau de Paris*, vol. iv.) thought that it prevailed less in England than France. At present the proportion is certainly reversed.

With respect to the causes of suicide, some curious results have been obtained by statisticians. [STATISTICS.] It appears from a classification of 134 suicides committed in ten years at Geneva (by M. Prevost, in vol. xv. of *Annales de Hygiène*), that the following causes produced them:—

Disease	34
Mental alienation	24
Pecuniary misfortunes	19
Domestic *chagrins*	15
Melancholy, cause unknown	13
Misconduct, drunkenness	10
Fear of punishment, remorse	6
Chagrins of love	7
Gambling and lotteries	4
Mysticism	2

Comparing these with other accounts, it

would seem that love produces at Paris $\frac{1}{26}$ of the suicides committed, at Geneva $\frac{1}{22}$, at Petersburg $\frac{1}{8}$, if Mr. Schön is to be believed; a singular contrast to the commonly supposed effects of climate. Domestic griefs at Paris (from 1794 to 1823), $\frac{1}{5}$; at Geneva the same. Misconduct at Paris $\frac{1}{23}$, at Geneva $\frac{1}{13}$, at Petersburg $\frac{1}{8}$. Gambling at Paris $\frac{1}{43}$, at Geneva $\frac{1}{14}$. Some of these results, in Paris and Geneva, are certainly remarkable for their correspondence. (See an essay of M. Brouc, in vol. xvi. of the *Annales de Hygiène*, already cited. The reader may consult also M. de Villeneuve Bargemont, *Econ. Politique Chrétienne.*)

If such official returns as we possess can be trusted, it would appear that suicide for about 20 years after 1817 was increasing but slowly in Paris, stationary in London; in the former city between 1 in 2,000 and 1 in 3,000, in the latter between 1 in 6,000 and 1 in 7,000.

The tables given below (from the Registrar-General's annual report) suggest that suicide is on the increase. The first gives an account of the five years ending with 1856; the second of seven years ending with 1864. By an oversight, it would seem, no statistics of suicide in England and Wales were given for the year 1857; for self-sought was not distinguished from accidental death in the returns of that year.

It appears that the number of suicides is understated, and we are informed that it should be raised by about a ninth part, if the coroner's returns to the Home Office be taken as the basis of an estimate. It is believed that a certain number of persons found drowned may be considered as unrecognised suicides. One of the most exhaustive and valuable works on this subject is the treatise, *Du Suicide*, of M. E. Lise (Paris, J. B. Baillière, 1856).

Number of Suicides in London in the seven years 1858 to 1864	1,256	524

Suicide is ranked by the English law as a peculiar species of felony; and, like other felonies, cannot be committed by persons under the age of discretion, or insane. From very ancient times (see Bracton) the law imposed the forfeiture of personal property as a consequent of it; and a felo de se (as a wilful suicide is termed) forfeits all chattels, real and personal. But the offence was never attended with corruption of blood, or the forfeiture of lands of inheritance (for this was consequent on *attainder*, the result of *sentence*, and a dead man cannot be tried or sentenced), so that the will of a felo de se stands good as to realty. In order to vest these chattels in the crown, the fact of self-murder must be proved by an inquisition, which the coroner is the proper officer to hold. In addition, the law formerly required that a self-murderer should be buried in a highway, with a stake driven through his body. Now, by 4 Geo. IV. c. 52, his remains are to be privately buried at night in the churchyard. But the canon law (confirmed by the rubric in the Common Prayer Book) forbids the performance of Christian rites over them.

Suit. In Law, proceedings in the Court of Chancery, corresponding to an action at law, are so called.

Sulcate (Lat. sulcatus, *furrowed*). In Zoology, when a surface is deeply impressed with longitudinal parallel lines.

Sulphamide. A crystallised compound obtained by the action of anhydrous sulphuric acid on ammonia. A compound resulting from the action of ammonia upon chlorsulphuryl has also received the same name.

Sulphate of Baryta. [Baroselenite.]

Sulphates. Salts derived from sulphuric acid; green vitriol is a *sulphate* of the protoxide of iron. Glauber's salt is a *sulphate* of soda.

Sulphides, Sulphurets. Compounds of sulphur with electro-positive or inflammable bodies. The most common ores of copper and of lead are *sulphides* or *sulphurets* of those metals.

Sulphites. Salts of the sulphurous acid.

Sulphocyanic Acid. This acid was discovered in 1808 by Mr. Porrett, who ascertained it to be a compound of sulphur, carbon, hydrogen, and nitrogen; he called it *sulphuretted chyazic acid*, the term *chyazic* being composed of the initial letters of carbon, hydrogen, and azote. It is formed by distilling a strong solution of sulphocyanide of potassium with phosphoric acid, when sulphocyanic (or more properly *hydro-sulphocyanic*) acid passes over into the recipient, and phosphate of potassa remains in the retort. So obtained, it is a liquid of a slight pink hue, and smells somewhat like vinegar. The strongest solution has a specific gravity of 1·022: boils at 217°, and crystallises at 55° in six-sided prisms. It gives a characteristic deep red solution with persalts of iron; with a salt of copper it gives a white precipitate. It is composed of C_2NS_2H.

Sulphocyanide of potassium is obtained by mixing equal weights of powdered sulphur and ferrocyanide of potassium, and keeping them in fusion for half an hour in a flask; when cold, reduce the mass to powder, and digest it in water; filter the solution, and add a sufficiency of caustic potash solution to throw down the iron.

Sulphonaphthalic Acid. A compound derived from sulphuric acid and naphthalin.

Sulphovinic Acid. *Sulphethylic acid.* An acid formed by the action of sulphuric acid upon alcohol. It consists of a molecule of sulphuric acid in which an atom of hydrogen has been substituted by ethyl. Its formula is $S_2O_8(C_4H_5)H$.

Sulphur (Dutch solfer, Fr. soufre). *Brimstone.* A yellow brittle mineral found in various parts of the world, but most abundantly in volcanic regions. Europe is supplied with it chiefly from the south of Italy and Sicily, usually associated with sulphate of strontia or gypsum. It most commonly occurs massive; but it is sometimes met with crystallised in the form of an acute rhombic octahedron. Sulphur is principally employed in the arts for the manufacture of sulphuric acid; very little of the native mineral, however, is made use of for this purpose, the chief source of supply being iron pyrites or bisulphide of iron, which when calcined evolves its sulphur as sulphurous acid. Native sulphur is chiefly used for gunpowder-making and for sulphuring vines.

Small quantities of sulphur also occur in several animal and vegetable products, and are frequently recognised by the odour of sulphuretted hydrogen which they evolve during putrefaction. Sulphur is a non-conductor of electricity, insipid, and inodorous, unless rubbed or heated, when it evolves a sulphurous smell. Its specific gravity is 1·99. It melts at about 216°; and when heated to about 250° it becomes a limpid, amber-coloured liquid; if the heat be raised to about 450°, it again becomes viscid and deeper coloured; at 480° up to its boiling point it acquires rather more fluidity; at about 600° it rises rapidly in vapour, and in close vessels condenses in the form of a fine yellow powder, composed of crystalline grains: in this state it is called *flowers of sulphur*. It boils at 836°. The earthy and metallic impurities which, with a portion of sulphur, remain in the subliming vessel, were formerly called *sulphur vivum*. When sulphur in its viscid state of fusion is poured into water it becomes a ductile mass, which slowly hardens, and which is often used for taking impressions of seals and medals. When sulphur is in the form of vapour it is of a dense orange colour; its specific gravity in that state is about 6·6, and 100 cubic inches of it should therefore weigh about 206 grains.

Another form of sulphur, sometimes called *milk of sulphur* (lac sulphuris), is obtained by precipitating sulphur by muriatic acid from certain of its alkaline solutions. When sulphur

which has been melted is suffered to cool slowly, its interior often exhibits prismatic crystals, and very beautiful specimens of this artificial crystallisation of sulphur may be obtained by melting a few pounds of it in a crucible or ladle, and, when it is partially cooled, piercing the outer crust and inverting the vessel, so that the interior liquid part may run out; on breaking the mass when cold, the cavity will be found lined with prismatic crystals.

The results of the combustion of sulphur, its atomic weight (16), and several other details respecting its combinations and uses, are given under the heads of SULPHURETTED HYDROGEN, SULPHURIC ACID, and SULPHUROUS ACID.

Sulphur is insoluble in water; it dissolves in bisulphide of carbon, and is deposited in small crystals as the solution evaporates. It is also soluble in alcohol, if both substances be brought together in the state of vapour. It combines with chlorine, bromine, and iodine. Its native combinations with the metals form some of the most important ores. It is from the sulphides of lead and of copper that the commercial demands for these metals are almost exclusively supplied.

Sulphur is of great importance in the arts. It is used extensively in the manufacture of gunpowder, and in the formation of sulphuric acid, or oil of vitriol. It is also used in medicine.

Sulphur Salts. Chemists have applied this term to certain *double sulphides*. The sulphides of the most electro-positive metals have been termed *sulphur bases*, such as the protosulphides of potassium, sodium, barium, &c.; whilst the sulphides of arsenic, antimony, &c., the bisulphide of carbon, and sulphuretted hydrogen, have been called *sulphur acids*; and the compounds resulting from the union of a sulphide of the former with one of the latter class are *sulphur salts*.

Sulphuration. The process by which certain silk, cotton, and woollen goods are subjected to the fumes of burning sulphur, or sulphurous acid, for the purpose of decolouring or bleaching. The rooms or chambers in which the operation is conducted are often of considerable dimensions, and fitted with poles and frames on which the blankets, shawls, and similar articles may be suspended. The straw used in the manufacture of hats is similarly bleached or sulphured. [SULPHUROUS ACID.]

Sulphureous Springs. [SPRINGS.]

Sulphuretted Hydrogen. *Hydro-sulphuric acid.* A gaseous compound of one atom of sulphur = 16 + 1 atom of hydrogen = 1. The equivalent, therefore, of sulphuretted hydrogen is 17. This gas was first examined by Scheele in 1777. It may be obtained by acting upon sulphuret of antimony by muriatic acid, or upon protosulphuret of iron by diluted sulphuric acid, and is immediately recognised by its peculiar fœtid odour, which is so diffusible that a single cubic inch of it escaping into the atmosphere of a large room is soon everywhere perceptible. It is very injurious to respiration; 100 cubic inches weigh about 38 grains, its specific gravity compared with air being as 1,174 to 1,000, or, compared with hydrogen, as 17 to 1. It is liquefied by a pressure of 17 atmospheres at 50°. Water agitated with this gas takes up three times its own volume, and acquires a bitterish nauseous flavour with the odour which characterises the Harrogate and Aix-la-Chapelle waters, which derive their chief peculiarities from the presence of this gas. Sulphuretted hydrogen extinguishes flame; but is itself inflammable in contact with air, burning with a blue flame. When mixed with excess of oxygen and inflamed, it explodes, and the mixture is converted into sulphurous acid and water. One volume of the gas requires one volume and a half of oxygen for its entire combustion, and the results are water, and one volume of gaseous sulphurous acid. This gas is immediately decomposed by chlorine and by iodine, which, if not added in excess, throw down its sulphur and combine with its hydrogen. It is unequivocally recognised by its peculiar odour, and by its blackening the salts of lead. Sulphuretted hydrogen, diluted with 20,000 measures of pure hydrogen, sensibly blackens a piece of paper which has been dipped into a solution of acetate of lead: white lead is also immediately discoloured by it; hence the mischief which it does to white paint, and to pictures. The aqueous solution of sulphuretted hydrogen reddens litmus; and inasmuch as it combines with certain bases, it is properly considered as a weak acid.

Sulphuric Acid. *Oil of vitriol.* This most important acid was discovered by Basil Valentine, towards the end of the fifteenth century. It was formerly obtained by the distillation of green vitriol (sulphate of iron), and from its oily appearance it acquired the name, which it still bears, of *oil of vitriol*. In this country it is procured by burning seven or eight parts of sulphur, and at the same time decomposing in the same furnace one part of nitrate of soda or of potash with sulphuric acid. The sulphur is burnt in a furnace so contrived that a current of air carries the products of the combustion into a large leaden chamber, the bottom of which is covered to the depth of a few inches with water. The principal products of the combustion of the sulphur and of the decomposition of the nitre are sulphurous acid and peroxide of nitrogen; and these, together with atmospheric air and steam, which is admitted from several jets, form the contents of the chamber.

The sulphurous acid and peroxide of nitrogen, with a portion of water, combine to form a white crystalline substance, which, upon falling into the water of the chamber, is instantly decomposed. The peroxide of nitrogen imparts oxygen to the humid sulphurous acid, and so converts it into sulphuric acid; whilst the peroxide of nitrogen, having lost oxygen, reverts to the state of *nitric oxide*, which is given out into the air of the chamber, from which it

immediately again abstracts oxygen, and becoming peroxide of nitrogen, is again ready to acidify a new portion of sulphurous acid. The oxygen, therefore, is thus indirectly transferred to the sulphur, or to the sulphurous acid, from the atmosphere, through the medium of the attractive power of the nitric oxide for that element; and the circumstance that this process is repeated over and over again by the same portion of peroxide of nitrogen, accounts for the small quantity of nitre required in this curious process.

When the water in the chambers is rendered sufficiently acid, which is judged of by its specific gravity, it is drawn off into leaden boilers, where it is evaporated down to the density 1·76; after which, as it would then act upon the lead, it is transferred to platinum boilers supplied with still-heads, and is there brought to its proper degree of concentration by further distilling off a portion of the residuary water. This last process was formerly conducted, at great risk and inconvenience, in glass retorts: its present improvement shows a most important application of platinum, which is not acted upon by the boiling acid. Of late, sulphuric acid has been largely manufactured from the sulphur obtained by roasting common pyrites (sulphuret of iron); one of the objections to which is, that it almost always contains more or less arsenic, by which the resulting acid is therefore contaminated. The acid made from Sicilian sulphur is indeed not always free from this mischievous impurity.

Sulphuric acid is a limpid colourless fluid, of a specific gravity of 1·842. It boils at 640°; it freezes at −30°; but the temperature at which the diluted acid congeals is singularly modified by the quantity of water which it contains. When of the specific gravity of 1·78 (which may be regarded as a compound of one atom of dry acid and two of water), it freezes at 40°, and remains solid for a long time at several degrees above that point: if the density be either diminished or increased, a greater cold is required to congeal it.

It is acrid and caustic, and intensely acid in all its characters, even when largely diluted. Its attraction for bases is such that it separates or expels all other acids more or less perfectly from their combinations. Its affinity for water is such that it rapidly absorbs it from the atmosphere, and when mixed with water much heat is evolved: thus by suddenly mixing four parts of the acid and one of water at 60°, the temperature rises to 300°. Its attraction for water also causes the sudden liquefaction of snow; and if mixed with it in due proportion, an intense cold is the consequence. It acts energetically upon animal and vegetable substances, generally charring them, and often, as in the case of *sugar*, with singular rapidity.

This acid, as it usually occurs in commerce, under the name of *concentrated sulphuric acid*, is a compound of 1 atom of anhydrous acid and 1 of water. The anhydrous sulphuric acid (*sulphuric anhydride* of some writers) is constituted of 16 sulphur (1 atom) and 24 oxygen (3 atoms); its equivalent, therefore, is $16 + 24 = 40$: i. e. the composition of the acid as it exists in the *anhydrous sulphates*. The strongest liquid acid consists of 40 of the anhydrous acid (1 atom) and 9 water (one atom), and is therefore represented by the equivalent $40 + 9 = 49$. Sulphuric acid is, however, now generally considered to be a dibasic acid, and to have double the combining weight just given.

Sulphuric acid is an article much used in commerce; its purity and value are judged of by its specific gravity. Upon this subject Dr. Ure's tables may be consulted, as showing the quantity of real or *dry*, and of commercial acid, in diluted acid of all densities.

By the term *real*, *dry*, or *anhydrous sulphuric acid*, we mean that which exists in the sulphates, and which may be obtained in a separate state by distilling protosulphate of iron, or green vitriol, at a high temperature: there supervenes a dense brownish liquid, which emits vapour when exposed to air, and has hence been termed *fuming sulphuric acid*. On putting this into a retort to which a receiver surrounded by ice or snow is carefully adapted, and heating it gently, a vapour passes over, which condenses into a white crystalline solid; this, which is *anhydrous* or *glacial* sulphuric acid, liquefies at about 70°, and evaporates at about 112°. Yet, when combined with such portion of water as constitutes the above described liquid acid, it is one of the most fixed of fluids. It hisses when dropped into water in consequence of the great heat evolved.

The ready test of sulphuric acid is a soluble salt of baryta; the solution of chloride of barium is generally used, which, when dropped into any solution of free or combined sulphuric acid, announces its presence by a white cloud or precipitate of *sulphate of baryta*, which is insoluble in nitric acid. In the same way sulphuric acid, and the sulphates, are tests of baryta.

Sulphuric Ether. [ETHER.]

Sulphurous Acid. This acid consists of 32 sulphur + 32 oxygen; its equivalent being 64. It is obtained by heating sulphuric acid in contact with certain metals, which abstract an atom of its oxygen; such, for instance, as silver or mercury. It is also formed by burning sulphur in oxygen gas. One volume of water takes up about 40 volumes of sulphurous acid gas; so that it requires to be collected and preserved over mercury, or in dry stoppered phials. It has the well-known suffocating odour of burning sulphur, and is possessed of considerable bleaching powers; so that the fumes of burning sulphur are often used to whiten straw, and certain silk and cotton goods; and when certain flowers, such as violets, dahlias, &c., are exposed to such fumes, or to sulphurous acid, their colours are mostly destroyed. Upon other colouring matters it has little effect. 100 cubic inches of sulphurous acid gas weigh between 67 and 68 grains; its specific gravity compared with

atmospheric air being 2·22. It extinguishes flame, and kills animals. When subjected to the pressure of about two atmospheres, or when cooled down to 6°, it assumes a liquid form; and in this state it evaporates with such rapidity at common temperatures as to produce a most intense degree of cold, so that by its aid chlorine may be liquefied and mercury frozen. It combines with bases, and produces a class of salts called *sulphites*; they are characterised by emitting sulphurous acid when acted upon by sulphuric acid, and by becoming converted into sulphates by oxidising agents.

Sultan (an Arabic word). The title of various Mohammedan princes besides the Ottoman emperor or grand sultan, to whom it is commonly given by Europeans, but whose peculiar title is Padishah. The princes of the deposed family of the khan of the Crim Tartars are also styled *sultan*: as is also the pasha of Egypt in that country, although not by the court of Constantinople.

Sumach (Ger. and Fr.). The popular name of the woody plants which form the botanical genus RHUS. The same term is also applied to the powder of the leaves, peduncles, and young branches of the *Rhus Coriaria* and *Rhus Cotinus*, shrubs which grow in Hungary, the Banat, and the Illyrian provinces. That derived from both kinds contains tannin, with a little yellow colouring matter, and is a good deal employed for tanning light-coloured leathers; but the first is of the best quality. With mordants, it dyes nearly the same colours as galls. In calico-printing, sumach affords, with a mordant of tin, a yellow colour; with acetate of iron, weak or strong, a grey or black; and with sulphate of zinc, a brownish yellow. A decoction of sumach reddens litmus paper strongly; gives white flocks with the proto-muriate of tin; pale yellow flocks with alum; dark blue flocks with red sulphate of iron, with an abundant precipitate. In the south of France, the twigs and leaves of the *Coriaria myrtifolia* are used for dyeing under the name of *rédoul* or *rodou*. The imports for home consumption amount to about 200,000 cwt. a year.

Summation (Lat. summus, *highest*). In Mathematics, the operation of adding or finding the sum of several quantities. When the quantities to be added form a series, the sum of any number of terms is indicated by prefixing the *sign of summation* Σ to the general term; the *limits* of the sum are also sometimes indicated; thus $\sum_{i=1}^{i=n} a_i$ denotes the sum $a_1 + a_2 + \ldots + a_n$. Instances of summation will be found under INTEGRATION; DIFFERENCES, CALCULUS OF; and PROGRESSION.

Summer (A.-Sax. sumer, Ger. sommer). One of the four seasons of the year. The summer season, for the northern hemisphere, begins when the sun reaches the tropic of Cancer, and ends at the following equinox.

SUMMER (Fr. sommier; quasi trabs summaria, *an upper beam*). In Architecture, any large piece of timber supported on two strong piers or posts, and serving as a lintel to a door, window, &c. [BRESSUMMER.]

Summons, Writ of. In Law. All actions in the superior courts of common law are now commenced by a writ of summons in a prescribed form, viz. by a writ issued in the queen's name out of the court in which the action is brought, directed to the intended defendant, describing him as of the county and place where he is supposed to reside or be, and commanding him to cause an *appearance* to be entered for him in that court, in an action at the suit of the plaintiff, within eight days after the writ shall be served upon him (the defendant). The amount of the debt claimed, if the action be to recover a debt, with other requisite particulars, must be endorsed on the writ. The writ remains in force for six calendar months, but may be renewed as often as there may be occasion. (3 Steph. *Comm.*)

Sumptuary Laws (Lat. sumptus, *expense*). Laws intended to restrain the expenditure of citizens. Sumptuary laws abounded in ancient legislation. Thus, among the Romans, the Lex Orchia limited the number of guests at a feast; the Lex Fannia restricted the cost of an ordinary entertainment to ten *asses*, and so forth. They were also common in the earlier legislation of this country.

All sumptuary laws intended to 'check excess in apparel and prohibit costly clothes' (passed chiefly in the reigns of Edward III., Edward IV., and Henry VIII.) were repealed by 1 Jas. I. c. 25. But one statute prohibiting excess in diet, 10 Edw. III. c. 3, which enacted that no one should be served at dinner or supper with more than two courses, except on certain specified holidays, and which had long fallen into desuetude, was expressly repealed by 19 & 20 Vict. c. 64.

The most successful of such attempts to regulate prices have been those which fixed the wages of labour. It was quite in accordance with this disposition to interfere with supply and demand, that enactments were made with a view to control expenditure; and, therefore, towards the conclusion of the fourteenth century, and subsequently, a variety of statutes were passed prohibiting certain kinds of dress, or at least limiting them to certain ranks in society, and defining, often with very great minuteness, what should be the customary habits and food of other ranks.

There will always be a question as to the propriety of an administration attempting to prohibit acts which are said not to be mala per se, or indeed any acts which have no directly evil effect on the rights of others. But of these prohibitions, none is more certain to be evaded than sumptuary laws. Individuals will be slow to recognise the right of government in such action, and when a license is given to some persons which is not accorded to others, every person is impelled to challenge and traverse the law. In a community like the Spartan, where abstinence was enforced on all alike, it was impossible to maintain the law. In our own

country, during the existence of the Gin Act, intemperance was never so common; and it is averred that even where a popular legislature, as in the state of Maine, has prohibited the sale of intoxicating liquors, as much or nearly as much is sold secretly as before was sold openly. But the case is still stronger when the law is intended to affect some persons and to give license to others.

It may be further remarked, that the promulgation of sumptuary laws depends necessarily on the ideas entertained of the province of government. The modern theory, which tends to confine the action of government more and more to the protection of person and property, leaves no room for any such legislation [Liberty]; and this tendency acquires naturally a greater force in large kingdoms than in small states. In the latter, the idea of the state or society is sure to override indefinitely the idea of the individual; and thus a sumptuary legislation is as natural to the ancient Roman republic as to that of Sparta. In the former, the citizen, although he retained his own home and to a certain extent the privacy of his house, was regarded as wholly subordinate to the state, which could interfere with him at its will; in the latter, the citizen can scarcely be considered as a private person at all. [Syssitia.] According to the Aristotelian theory of politics, sumptuary laws formed an indispensable part of every civil code. If the state was bound, as Aristotle maintained, to see to and insure the mental and moral welfare of all its citizens, it was bound to prescribe not merely the books which they were to read, but the dishes which they should eat, and the clothes which they must wear.

In their practical working, sumptuary laws in more modern times have been used as instruments for keeping up the distinctions of classes, and thus as a means for upholding the power and influence of an aristocracy. The theories of religion disseminated by the mediæval clergy united with these political prejudices, as Hallam has remarked (*Middle Ages*, ch. ix. part ii.), 'to render all increase of general comforts odious under the name of luxury; but while the kings of France and England multiplied laws about the food and dress of their subjects, they were themselves more egregious spendthrifts than any others in their dominions, and contributed far more by their love of pageantry to excite a taste for dissipation in their people than by their ordinances to repress it.'

Sun (the Sanscrit root is sur, *to glitter*, Gr. ἥλιος, Lat. sol, Ger. sonne). In Astronomy, the central body of our system, about which all the planets and comets revolve, and by which their motions are regulated and controlled. The sun is the source of light and heat, and therefore the primary cause of all the motions and changes effected on the surface of the earth by those great agents of nature.

Apparent Magnitude of the Sun.—The sun presents to the naked eye the appearance of a luminous circular disc, subtending an angle of rather more than half a degree. But on measuring accurately the diameter of the disc, it is found to be not always the same, but subject to an annual variation. In fact, as the earth describes an ellipse, of which the sun occupies one of the foci, its distance from the sun is constantly changing, and the variation of the sun's apparent diameter is a necessary consequence of the change of distance. When the earth is in its perihelion, or point of its orbit nearest to the sun, the sun's apparent diameter is 32′ 36·41″, and when the earth is at its aphelion, or the most distant point, the apparent diameter is 32′ 3·64″.

The accompanying table of elements gives the latest values obtained.

	Old Value	New Value
Equatorial horizontal parallax	8·5776″	8·915″
Mean distance from the Earth	95,274,000	91,678,000
Time of rotation	Variable with the latitude. The rotation in 24 hours of mean solar time is expressed by the formula, 865′ ± 165′ sin $\frac{1}{2}$ *l*.	
Diameter in miles	888,646	853,380
Inclination of axis to plane of ecliptic	82° 45	for 1850
Longitude of node	73 40	for 1850
Mass (Earth's as 1 =)	354,936	316,047
Density (Earth's as 1 =)	0·250	
Volume (Earth's as 1 =)	1,415,225	1,260,160
Force of gravity at Equator (Earth's as 1 =)	28·7	27·6
Apparent diameter as seen from the Earth, maximum		32′ 36·41″
Apparent diameter as seen from the Earth, minimum		32′ 3·64″

Distance of the Sun.—The sun's true distance is found from his horizontal parallax. This is so small a quantity that practically it is not possible to determine it in the usual way by observations made on opposite sides of the earth; but the astronomical phenomena of the transits of the planet Venus over the sun's disc afford the means of determining it with the utmost precision. From the transits which occurred in the last century, a parallax was obtained of 8·5776 (shown as the old value in the above table); i.e. if an observer could be placed at the centre of the sun, the earth's semidiameter would be seen by him under an angle of 8·6″. From this it followed that the mean distance of the sun from the earth must be at least equal to 24,047 times the earth's radius; and as the radius of the earth is nearly 4,000 miles, it follows that the sun's true distance, calculated from that parallax, must be about 95,000,000 miles.

As mentioned, however, in the article Planet, recent investigations have resulted in a smaller value of this distance. Observations of the planet Mars at opposition, investigations into the motions of the moon and masses of the planets, and the velocity of light, all agree in a remarkable manner in showing that some 3,000,000 miles must be deducted from the old value.

In order to obtain a more distinct idea of this enormous distance, we may compute the time in which it would be passed by some of the swiftest motions with which we are acquainted. A cannon ball, fired with a charge of 8 lbs. of gunpowder, is projected with a velocity of about 1,600 feet in a second. Supposing it were to move towards the sun with a uniform velocity, it would require nearly ten years to reach its surface. Light itself, which travels with the astonishing velocity of 192,500 miles in a second, only reaches the earth eight minutes and eighteen seconds after leaving the sun's surface.

The distance and apparent diameter of the sun being known, it is easy to compute its real dimensions. The new value of the diameter is 853,380 miles. The mean distance of the moon being rather less than 60 times the earth's radius, if the sun's centre were placed at the centre of the earth, its surface would be at twice the distance of the moon's orbit; and the volume of a sphere whose radius is equal to that of the moon's orbit would be only an eighth part of the volume of the sun. The sun's volume is 500 times greater than the volumes of all the planets taken together.

Mass and Density of the Sun.—The magnitude and distance of the sun are determined by direct observation; his mass as compared with that of the earth is deduced from the law of universal gravitation.

We can determine on the earth at what rate a body falls to the earth. The earth's orbit tells us at what rate the earth itself falls to the sun. Experiment tells us that, on the surface of our globe, a heavy body traverses sixteen feet during the first second of its fall; and as, according to Newton's theory, the attraction of a sphere acts on external bodies, as if the entire mass of the sphere were concentrated at its centre, we must consider the heavy body falling on the surface of the terrestrial globe, as situated at a distance from the centre of attraction equal to the radius of the earth. The mass of the earth, then, acting on a body situated at a distance of 4,000 miles, causes it to fall 16 feet in one second. On the other hand, the earth itself gravitates towards the sun; the orbit which it thus describes in a year shows how much it falls towards the sun during the first second of fall. The distance is found to be ·0099 feet. We must now reduce this measure of the attractive energy of the sun to what it would be at a distance from its centre equal to 4,000 miles, or to the terrestrial radius, a distance 23,984 times smaller than the sun's distance according to the old value.

The law of gravitation indicates that the preceding number must be multiplied by the square of 23,984 feet. Doing this, we find that the mass of the sun, acting on a body situated at a distance of 4,000 miles from its centre, causes it to travel, in the first second, 5,708,763 feet, or 1,075 miles. We can now compare the mass of the sun with that of the earth since we know the actions of these two masses, on a body situated at the same distance from their centres; and it is clear, that the mass of the sun is by so much greater than that of the earth, as the number 5,708,763 is greater than 16. Dividing, we find in round numbers 355,000. We must have, then, 355,000 globes of the same weight as ours to balance the sun.

The density of a body is directly as its mass, and inversely as its volume. If, therefore, we call the density of the earth 1, the ratio of the density of the sun to that of the earth will be, to take the new value, as $\frac{316047}{1260160}$ to 1, or as 0·25 nearly to 1, or as 0·254, whence the sun's density is about one-fourth of that of the earth.

In order to compare the force of solar gravity at the sun's surface with that of terrestrial gravity at the earth's surface, we must again recollect that the attraction of a body on an exterior point is directly as the mass of the attracting body, and inversely as the square of the distance of the point from its centre. Hence, a body, which at the earth's surface weighs one pound, would weigh 27·6 pounds if carried to the surface of the sun. An ordinary man would not only be unable to sustain his own weight on the sun, but would be literally crushed under the load.

Rotation of the Sun.—The sun, when viewed through the telescope, is generally observed to have on its surface a number of dark patches or *spots*, which being observed from day to day are found not to remain in the same place, but to move across the surface, without changing their relative positions to any great extent. These phenomena are accounted for by supposing the sun to have a rotatory motion about an axis from west to east. The early observations of Delambre, Bianchi, and Laugier, were by no means concordant, but an average rotation of 25 days was obtained. The recent discovery that the time of rotation of the photosphere, or the external bright cloudy envelope which we see, varies with the latitude of the part observed, is due to Mr. Carrington.

Spots on the Sun.—Numerous hypotheses have been formed respecting the solar spots. They began to attract attention soon after the discovery of the telescope. Scheiner supposed them to be planets revolving at no great distance from the sun's surface. Galileo and Hevelius conceived them to be a sort of *scoriæ* or *scum* formed at the surface of the sun, and floating in an ocean of liquid matter. Lahire supposed them to be protuberant parts of solid, opaque, and irregular masses, floating in the liquid matter of the sun. Dr. Wilson, of Glasgow, accounted for the spots by supposing the sun to consist of a dark nucleus, covered to a certain depth by luminous matter, through which cavities or gulfs are made by volcanic or other actions, thus permitting the dark nucleus to be seen. Lalande suggested that the spots or opaque bodies may be merely the summits of mountains, usually covered by the igneous fluid, but which, by the flux and reflux of the fluid, sometimes protrude

beyond its surface, and thus become visible. Sir William Herschel, following Dr. Wilson, considered the luminous strata of the atmosphere to be sustained far above the level of the solid body by a transparent elastic medium, carrying on its upper surface (or rather at some considerably lower level within its depth) a cloudy stratum, which, being strongly illuminated from above, reflects a considerable portion of the light to our eyes, and forms a penumbra, while the solid body shaded by the clouds reflects none. The temporary removal of both the strata, but more of the upper than the lower, is, in his opinion, effected by powerful upward currents of the atmosphere, arising, perhaps, from spiracles in the body, or from local agitations. (Sir J. Herschel's *Outlines of Astronomy*, p. 229.) The most recent ideas on the subject, derived from observation and considerations of the sun's physical constitution, are opposed to all these hypotheses, as it is now accepted on all hands that the sun's light and heat are really due to a state of incandescence of a body surrounded by an absorbing atmosphere. Almost all the phenomena presented both by sun-spots, faculæ, and the general surface, are satisfied by supposing the photosphere to be built up of clouds. If the margin of a sun-spot be observed, the bright granules which, as pointed out by Sir William Herschel, cover the whole surface of the sun, are observed to change their generally circular or nearly circular shape for a more elongated one as they descend down the slope of the penumbra, and on rarer occasions still they are seen to float over the region occupied by the umbra and melt in their passage. Hence the spots are supposed to be openings in the cloudy stratum, and the question arises, What is the dark portion then rendered visible? M. Faye explains it by looking upon the photosphere as a shell enveloping a nebula. Mr. Balfour Stewart and others ascribe it to a reduction of temperature caused by a downward current of cold air.

The solar spots are exceedingly irregular in shape; and, when watched attentively for some time, they are observed to enlarge and contract, and to change perpetually their form and outline. Frequently they disappear before they approach the edge of the disc, and others break out suddenly in places where none were seen before. Sometimes a spot has been seen to break up into several parts, and the fragments to separate from each other, as if acted upon by an explosive force. The *nucleus* of a spot is perfectly black, and sharply defined; and is surrounded by an *umbra*, or border of a fainter shade; this, again, is surrounded by a penumbra. In the neighbourhood of large spots, or in places where they are numerous, bright streaks, or portions more luminous than the general surface of the sun, called *faculæ*, are frequently seen. Among these faculæ spots are often observed to break out; and when this does not happen, they are generally succeeded by spots, larger in proportion to the brightness of the antecedent faculæ. The region of the spots is generally confined to the parts of the sun within about 30° of the equator, beyond which they are rarely seen.

The magnitude of the spots, and the scale on which their movements are performed, are not the least remarkable circumstances connected with the phenomena. At the distance of the sun, a line which subtends an angle of one second is equal to about 460 miles, and a circle of that diameter has an area of about 166,000 miles; and this is the smallest space which can be distinctly discerned on the sun's disc. But a spot was observed by Mayer having a diameter equal to $\frac{1}{20}$ of the diameter of the sun, or upwards of 96″, and consequently (supposing it to be circular) covering an area of 1,520 millions of square miles—upwards of 30 times the whole surface of the earth.

Physical Constitution of the Sun.—Our most recent conception of the physical constitution of the sun is derived from a discovery of Kirchhoff's, which shows that it is the solid or liquid nucleus of the sun, and not the atmosphere, which is the principal source of light, and that the light so emitted has certain colours filtered out during its passage through the sun's atmosphere. The same philosopher has also shown the existence of the metals sodium, potassium, magnesium, iron, chromium, and nickel in the atmosphere of the sun. For further information respecting these discoveries, see SPECTRUM ANALYSIS.

Considering the enormous and incessant emanation of light and heat from the sun, the question has often arisen whether the volume of the sun undergoes any diminution. If the high temperature is kept up by friction or by the precipitation of meteoric matter into the sun, as first suggested by Mayer, no loss of volume would be sustained; but if the heat and light are produced merely by the cooling of the body of the sun, a diminution of volume would appear to be a necessary consequence. Observation, however, can afford us no information on this head; for, supposing an actual diminution to be going on at such a rate as to lessen the diameter by two feet in 24 hours (which, having regard to the sun's magnitude, may be considered as enormous), 3,000 years would elapse before the diminution of the apparent diameter would amount to a single second. Buffon supposed the sun to be an immense furnace, alimented by comets precipitating themselves into it from time to time.

Atmosphere of the Sun.—The existence of a solar atmosphere was inferred by Bouguer from a comparison of the intensity of radiation at different points of the disc. By reason of the globular figure of the sun, a much larger portion of the surface towards the border is comprehended under a given visual angle than at the centre; and, as every point of the surface must be supposed to radiate equally in all directions, it follows that the intensity of light near the border should be greater than at the centre, in proportion to the greater extent of surface

comprised under the same angle. Bouguer's observations, however, led him to infer that the light from the centre of the disc had a greater intensity than that which proceeded from the borders, a circumstance which would be explained on the supposition of its being absorbed in a greater proportion by having to traverse a greater extent of atmosphere. These observations have been recently confirmed by Roscoe, who has found that the photographic power of the sun's disc diminishes towards the edge. The existence of a solar atmosphere is also indicated by the ring of light and the singular red protuberances seen in solar eclipses, and especially in those of 1851 and 1861.

Sun's Position and Proper Motion in the Heavens.—The discoveries in sidereal astronomy which have been made in modern times, all tend to establish the hypothesis of a similarity of condition and a community of nature between the sun and the fixed stars. The prevalence of gravitation among these remote bodies, following the law observed in the solar system, is no longer a matter of speculation; the proof being afforded by the elliptic orbits described by so many of the double stars about their common centre of gravity. With respect to the place which the sun occupies in the heavens, we have, says Sir J. Herschel (*Mem. Royal Astron. Society*, vol. xi.), almost ocular evidence that our system is eccentrically situated within the region bounded by the *milky way*, and nearer to its southern than to its northern portion. It was also an opinion of Sir William Herschel, now confirmed beyond contradiction, that the sun, like many of the fixed stars, has a proper motion in space, in consequence of which it is at present advancing towards a point of the heavens within the constellation *Hercules*. Yet, though the *fact* that the sun has a proper motion in space may be regarded as certain, many centuries of observation may be required to enable astronomers to detect its laws, or even to arrive at any definite conclusions respecting the remote centre about which it is performed. An extension of Kirchhoff's discovery before mentioned has taught us that the physical constitution of the sun and stars are identical in the main, though the components of the nuclei and atmospheres may vary within certain limits. (Sir J. Herschel's *Astronomy*; Lalande, tom. iii.; Biot, *Astronomie Physique*; Laplace, *Système du Monde*; Delambre, *Astronomie*; Argelander, Struve, and Galloway, *On the Proper Motion of the Solar System*; Main, 'On the Proper Motions of the Stars,' in *Greenwich Catalogue*, &c.; *The Heavens*.) [STARS.]

Sun Opal. A name for Fire Opal, or for that variety of Opal which displays bright yellow and hyacinth-red reflections. It is found at Zimapan in Mexico; also in Cornwall, near St. Just, and at Huel Spinster and Rosewarne Mine.

Sun Worship. The evidence of language, as well as that of mythology, tends to show the general, if not the universal, existence of sun worship among the various tribes of men in the earliest ages. On the mental process which may have led to such a worship, something has been said in the articles LANGUAGE, MONOTHEISM, MYTHOLOGY, and POLYTHEISM. The worship naturally assumed different forms according to the peculiar tastes and tempers of the several nations; but the leading idea, which impressed itself especially on the Oriental mind, was that of the generative force of nature, as proceeding from the sun, and thus their worship of the sun was intimately connected with that of the LINGA, or PHALLUS, and YONI, answering to the Ashera and altar of Baal among the Jews, Phœnicians, and other Semitic peoples. This element was represented in the West chiefly in the MYSTERIES, and in the Phallic processions of Dionysus, &c. But the tendency of the Greek mind to invest with a human form the being who was supposed to direct each force in nature as distinguished from the force itself, brought the personal Apollo, or Dionysus, or Athena into a prominence which placed the worship of generative emblems more and more in the background, and invested it with an obscure and repulsive character; and thus to the Greek, Helios, the sun, became a secondary to Phœbus, the light-giver, standing to him in the relation of Nereus to Poseidon, or of Nephelê to Hera. In the *Odyssey*, Helios still has his sacred cattle in the Thrinakian land; but the legend is interesting chiefly as throwing light on the mythical phrases which seemed to have furnished a basis for many, if not most, of the incidents both of the *Odyssey* and the *Iliad*.

Sunday. The first day of the week, consecrated to the sun in heathen times. (Sir G. C. Lewis, *Astronomy of the Ancients*, p. 304 &c.) The solemnisation of this day dates from the earliest age of the Christian church, in memory of the death of Christ, and of the descent of the Holy Ghost. The Jewish Christians retained at the same time their Sabbath, the last day of the week; but this practice became obsolete early, at least in the Western church. The Sunday does not appear to have been strictly observed as a day of cessation from labour before the reign of Constantine. By the decree of that emperor (A.D. 321) public business and military exercises were suspended. The council of Laodicea (A.D. 360) forbade labour in general terms: and the laws of Theodosius (circ. A.D. 420) sanctioned this interdiction by civil penalties. [SABBATH.]

Sunday Letter. [DOMINICAL LETTER.]

Sunflower. [HELIANTHUS.]

Sunniah. The name assumed by the Mohammedans, as followers of the tradition or orthodox, in opposition to the Shiah sect, or the followers of Ali, who maintained that although Moawyiah, the first of the Ommiad dynasty of caliphs, had, by the forced abdication and murder of Hassan, possessed himself of the temporal power, yet the spiritual supre-

macy was inalienable from the direct descendants of the prophet. The followers of Ali have always been numerous; and the Persians, probably as much from national antipathies as from religious conviction, continue to assert the rights of the house of Ali. (Ockley's *History of the Saracens*.)

Sunstone. A resplendent variety of Felspar (Adularia) of a very pale yellowish colour; found in Siberia, Norway, and elsewhere. The play of colour which it exhibits arises from minute lamellar crystals of oxide of iron (Göthite) which are embedded in it.

Suovetaurilia (Lat. from sus, *a swine*; ovis, *a sheep*; and taurus, *a bull*). In Roman History, a quinquennial sacrifice, which consisted of the immolation of a sow, a sheep, and a bull; hence the name. [LUSTRATION.]

Supercargo. The person in a merchant ship appointed to superintend all the commercial transactions of the voyage.

Superdominant (Lat. super, *above*, and dominans, *governing*). In Music. In the descending scale, the sixth of the key.

Supererogation, Works of (Lat. supererogo, *to pay over and above*). In Theology, the belief that men may acquire merit in the eyes of God by good works beyond what are necessary for salvation. This notion is said by Protestants to have been first known about the twelfth or thirteenth century, and to have been founded upon what Roman Catholic theologians term *counsels of perfection*; i.e. rules which do not bind under the penalty of sin, but are useful only in carrying men to a higher degree of perfection than is requisite for ordinary Christians.

Superficial Measure. The measure of surfaces or areas; also called *square measure*. [MEASURE.]

Superficies (Lat.). A surface. The *superficial area* of a body is the quantity of surface which it possesses.

Superheated Steam. Steam to which an additional quantity of heat has been imparted subsequently to its generation, its volume being thus increased according to the law which governs the expansion of dry air by heat. The benefit of working steam at a high temperature is made apparent by the principles of thermo-dynamics, and in modern marine boilers the steam is very generally superheated by the waste heat of the smoke. Much superheating, however, occasions internal corrosion of the steam chest and of the engine, and also dries up the lubricating tallow of the piston and stuffing boxes, and burns out the hemp packing. In practice it is found that the steam should not be heated to a higher temperature than 315° Fahr.

Superior (Lat.). In Scottish Law, a superior is one who has made an original grant of heritable property with reservation of rent and service. The grantee is termed *vassal*: the interest of the grantor is *dominium directum*, that of the grantee *dominium utile*; or, the former *superiority*, the latter *property*. The reunion of these two rights in the same person is termed *consolidation*.

Superior Slope. In Fortification, the slope of the parapet outwards from the crest.

Superiors. In Printing, small letters or figures cast at the tops of the shank of types, thus (^{23}). They are generally used for references to marginal or foot notes, and in mathematical works.

Superlative (Lat. superlativus). In Grammar, the name vulgarly given to the so-called third degree in comparison, formed in the Teutonic languages by the additional syllable *est*.

Supernatural (Lat. super, *over*, and natura, *nature*). In the conflict of definitions propounded on this subject all that can be attempted in the present article is to give a brief sketch of the positions maintained by antagonistic thinkers.

These may be divided in the main into two classes: (1) those who hold that events have taken place in the world's history which cannot be referred to any law, and which, being displays of arbitrary power, and in this sense beyond nature, i.e. removed out of the ordinary chain of cause and effect, must be termed *absolute* miracles; and (2) those who maintain that all such events have been brought about in accordance with some further and higher laws which we have not yet been able to discover, and which, as having thus an exceptional and incomprehensible character, may be termed *relative* miracles.

The former position is maintained by Mr. Mozley (*Bampton Lectures*, 1865), more clearly, perhaps, than by any other writer of the present day. According to his definition, a miracle is a visible suspension of the order of nature for a providential purpose, serving as an evidence of revelation. Hence the coincidence of the miracle with the alleged Divine communication becomes an indispensable condition. No ordinary event could have this coincidence, inasmuch as it would be explained by its own place in nature. Hence it follows, that if a complete physical solution could be given of a whole miracle, 'it would cease from that moment to perform its functions of evidence; apparent evidence to those who had made the mistake, it could be none to us who had corrected it.' The evidential theory, thus adopted by Mr. Mozley, is regarded by others, who agree with him in many of his conclusions, as placing 'the supernatural in a light which makes it utterly incredible.' (*Christian Remembrancer*, October 1866.) Such writers maintain their position by asserting that the imparting of a revelation is not the sole or perhaps the chief end of God's dealings with man as set forth in the Old and New Testaments, and hat miracles belong to an order of events not more lying beyond the range of human experience than the facts of inductive science. According to this theory, miracles form 'that class of facts or phenomena which arise out of the relation in which man stands to God;' hence it follows that 'miracles at

least as great as those of Christ are day by day being transacted,' and that 'every time we kneel at the altar, we are bound to believe in a miracle second only to the Incarnation.' The miracles of Christ were 'the result of the hypostatic union,' their end being 'the accomplishment of the work of redemption.' These theological arguments, which will be put aside by those who think otherwise on the subject of the sacraments, or who put a different meaning on the term *Incarnation*, lead to the conclusion that the personal relation of man to God, 'if it is real, must be miraculous,' and that they who deny miracles must first 'deny a personal existence to man.' Hence, although 'great miracles like those of Christ no longer take place, because the gift residing in Christ is no longer in the world,' there still remain gifts of the Spirit, the same in kind. Far, then, from being past and exceptional acts on the part of God, miracles 'are part of a vast system now going on.'

This argument must be indefinitely affected by the definitions given of natural and mental action, and must indeed depend on the establishment of a distinction between the two; while it is further obvious that, although miracles as a class may come within the range of human experience, the several narratives of miracle must still, or rather on that very account, be subjected to a criticism based on the canons of historical credibility.

But more generally, the hypothesis accepted by recent writers is that of relative miracle. Thus Dr. M'Cosh (*The Supernatural in Relation to the Natural*) confines the word *miracle* 'to those events which were wrought in our world as a sign or proof of God's making a supernatural interposition or a revelation to man.' This definition, which, however, leaves the word *supernatural* undefined, seems to involve as the two conditions essential to a miracle, that they should be wrought by a Divine Power for a Divine purpose, and be of a nature such as could not be wrought by merely human contrivance. To this it has been replied, that the definition excludes from the class of miracles all those which are mentioned in the Bible as having been wrought for an evil purpose, and more especially those against which Moses is represented as warning the Israelites, if wrought by persons who invite them to the worship of false gods. It has been further argued, that, according to Dr. M'Cosh's definition, a miracle is only a superhuman work, and that this is not the sense in which anyone can have any difficulty in believing it, inasmuch as 'the powers and works of nature are all superhuman, more than man can account for in their origin, more than he can resist in their energy, more than he can understand in their effects.' But to this acceptation of the word Mr. Mansel (*Essay on Miracles*) seems to confine himself when he asserts that 'a superhuman authority needs to be substantiated by superhuman evidence, *and what is superhuman is miraculous*.' On this it has been remarked by the writer of an essay on 'The Supernatural' (*Edinburgh Review*, Oct. 1862), that Mr. Mansel's definition does not necessarily involve the idea of a violation of the laws of nature. 'It does not involve the idea of the exercise of will apart from the use of means; it does not involve, therefore, that idea which appears to many so difficult of conception. It simply supposes, without any attempt to fathom the relation in which God stands to His own laws, that out of His infinite knowledge of these laws, or of His infinite power of making them the instruments of His will, He may and He does use them for extraordinary indications of His presence.'

On the other hand, it has been urged that, whether this theory, which seems to make all miracle relative, be true in fact or not, it is one which was unknown to the writers of the Old Testament and the New, and is in opposition to all that they have said or related on the subject; that until there was some conception of an order of nature there could be no idea of miracle as a violation of that order; that for the Jewish and the early Christian writers a miracle was an event following no law, violating no order, but simply attesting the arbitrary action of a Being who could act in various ways at various times or in different places; that if they could have been brought to regard miracles simply as works beyond the reach of merely *human* powers, wrought by higher forces in accordance with existing but unknown laws, they would have ceased to see in miracles any value or to derive from them any consolation; that for them they were valuable and impressive, as being arbitrary and capricious combinations, which might break in upon a course of events of an ordinary character, but which might be so multiplied (as in the *Arabian Nights* fiction) as to become the rule rather than the exception. A confirmation of this view is found, it is said, in the tone of thought which characterised the Homeric age. In the words of Mr. Grote, if the old Greek 'could have been supplied with as perfect and philosophical a history of his own real past time, as we are now enabled to furnish with regard to the last century of England or France, faithfully recording all the successive events, and accounting for them by known positive laws, but introducing no special interventions of Zeus and Apollo, such a history would have appeared to him not merely unholy and unimpressive, but destitute of all plausibility or title to credence. It would have provoked in him the same feeling of incredulous aversion, as a description of the sun in a modern book on scientific astronomy.' (*History of Greece*, part i. ch. xvi.)

Apart from this idea of arbitrary action interfering in a world at no time and in no place governed by fixed and unvarying laws, miracles, it is said, must assume a merely relative character. Thus, the writer on

'The Supernatural,' already referred to, states that 'the reign of law in nature is, so far as we can observe it, universal;' and hence he rejects that idea of miracle which regards such alleged events as 'at variance with natural laws, above it, or in violation of it.' Hence, he adds, 'it would appear that to a man thoroughly possessed of the idea of natural law as universal, nothing ever could be admitted as supernatural, because on seeing any fact, however new, marvellous, or incomprehensible, he might escape into the conclusion that it was the result of some natural law of which he had before been ignorant.' This is the conclusion not 'of pride, but of humility of mind;' but in this case *nature* must be taken in its largest sense 'as including every agency which we see entering, or can conceive from analogy as capable of entering, into the causation of the world,'—in other words, nature must not be regarded 'in the narrow sense of physical (inorganic or unconscious?) nature,' for in this sense the human mind and will would be excluded from the range of things natural, although 'the agency of man is of all others the most natural, the one with which we are most familiar, the only one, in fact, which we can be said even in any measure to understand.' But the agency of man is bounded by his knowledge of natural laws, and of these laws he can only 'guide in a limited degree the mutual action and reaction. His ability to use them further is limited both by his want of knowledge, and his want of power.' Yet even so far as it already extends, scientific knowledge, which can present 'an endless series of wonderful phenomena (such as ice frozen in contact with red-hot crucibles) not belonging to the ordinary course of nature,' may be conceived as receiving hereafter an increase which may enable it to do many things which now would appear supernatural.' Still, to whatever extent this developement may be carried, we do not reach 'that idea of the supernatural which so many reject as inconceivable.' 'What, then,' the writer asks, 'is that idea? Have we not traced it to its den at last? By supernatural power do we not mean power independent of the use of means, as distinguished from power depending on knowledge, even infinite knowledge, of the means proper to be employed? This is the sense, probably the only sense, in which the supernatural is, to many minds, so difficult of belief. No man can have any difficulty in believing there are natural laws of which he is ignorant, nor in conceiving that there may be beings who do know them and can use them, even as he himself now uses the few laws with which he is acquainted. The real difficulty lies in the idea of will exercised without the use of means, not in the exercise of will through means which are beyond our knowledge. But have we any right to say that belief in this is essential to all religion? If we have not, then it is only putting, as so many other hasty sayings do put, additional difficulties in the way of religion.' If, as the writer argues, we have no certain reason for believing that God ever acts without means, then 'extraordinary manifestations of His will, signs and wonders, may be wrought, for aught we know, by similar instrumentality, only by the selection and use of laws of which man knows and can know nothing, and which, if he did know, he could not employ.' If, then, we 'once admit that there is a Being, who (irrespective of any theory as to the relation in which the laws of nature stand to His own will) has at least an infinite knowledge of those laws and an infinite power of putting them to use, then miracles lose every element of inconceivability.'

On this it has been remarked that, inasmuch as no miracle whatsoever can on this hypothesis be regarded as breaking in upon the constitution and course of nature, all those alleged miraculous events which seem to exhibit the working not of higher but of lower laws than those which govern the ordinary sequence of events must be excluded from the class of miracles, while at the same time the credibility of all narratives of miracle becomes a question of historical evidence, and of historical evidence only; that if, after being subjected to all the tests of historical credibility, these narratives emerge from the ordeal as unscathed as the history of the Peloponnesian war by Thucydides, then the miracles which they may relate may be referred to a class of events belonging to a higher range of causation; but that, if they fail under the tests applied to them, if it appear that the witnesses are prejudiced, or enthusiastic, or untrustworthy, or that the evidence is not that of contemporary witnesses, or that from any cause they may not thoroughly be relied on, then the alleged miraculous events must be put aside as not calling even for discussion.

But, further, it has been maintained that this argument which ascribes to all miracles a merely relative nature, reduces the matter to a question of words, inasmuch as a miracle which is not an absolute miracle is, in strictness of speech, no *miracle* or object of astonishment at all; that, although we cannot pretend to understand the laws of gravitation, no one pretends that that law is a miracle, and that the assertion that an event exhibiting the action of a law higher than that of gravitation is a miracle, does nothing more than extend the region of merely verbal controversy. For, on this principle, it seems to follow that no miracle can break in upon the strict continuity of causation, while, if it does break in upon it, 'it becomes unmeaning and self-contradictory, as implying imperfection in a perfect government, disorder in inevitable order, something overlooked and unexpected in the plans of supreme wisdom, requiring interpolation and revision.'

But, again, the idea of miracle, even in the relative sense, was, it is argued (Mackay, *Tübingen School*, 34), 'from the first compli-

cated and impeded by the general belief in demoniacal agency and sorcery, so that an ulterior criterion was wanted to distinguish true miracles from false or diabolical ones. This could only be found in the moral character of the work, or the beneficent tendencies of the accompanying doctrine, and the fathers were thus for several reasons induced to disparage mere signs or external displays of power, and to appeal to the doctrine to prove the miracles on which it was ostensibly based. This, however, was to refer the entire question of revelation to the paramount adjudication of conscience, and Protestant theology was obliged to lay the more stress on the primitive miracles as it repudiated later ones.'

At this point we are brought to the question of biblical miracles as distinct from those which have been termed ecclesiastical. Between these no positive line of demarcation has been laid down; but Dean Milman (*History of Latin Christianity*) discerns in the Scriptural miracles characteristics which he is unable to find in those of post-apostolic ages. Dr. Newman, on the other hand, in his well-known *Essay on Ecclesiastical Miracles*, prefixed to the Oxford translation of Fleury's *Ecclesiastical History*, argues that the Biblical and ecclesiastical miracles must stand or fall together, that the characteristics of both classes of events are essentially the same, that if some of the ecclesiastical miracles are extravagant and grotesque, the same features are found in some of the miracles related in the Bible, and that miracles such as the distillation of healing oil from St. Walburga's bones, may be paralleled by the miracle wrought by the dead bones of Elisha. On the hypothesis that the biblical miracles are all true, it was argued that 'the multitude of false miracles ranged alongside of the inspired narratives left the true miracles contained in the latter just where they are now; their truth was not affected by the fabrication of the others, and they challenged to themselves the belief of all men as imperatively as they do now. The question, then, is no longer one of authority but of evidence, and according to the quality of that which is offered a miracle must either be accepted unhesitatingly or be held in abeyance, or regarded as doubtful, or rejected altogether.' (Cox's *Life of St. Boniface*, appendix i. p. 143.)

From this historical argument, founded on the hypothesis of absolute miracle, we have to return to the argument relating to the possibility of even relative or notional miracles. On this subject it was maintained by Spinoza that 'in the view of reason there cannot be two crossing and contending wills and principles in God, that nature's law is itself the continuous manifestation and accomplishment of necessary and immanent perfection, and that to suppose anything really contradicting this perfection, or performed by the Deity in opposition to it, were to make Him contradict Himself.' If, again, God and nature were regarded as two separate agencies, operating exclusively of each other, yet 'if both powers be recognised as acting necessarily and unitedly, miracle ceases to have any objective meaning, and is really only a showy costume invented to disguise the inanity of human ignorance.' (Mackay, *Tübingen School*, 37.)

On the way in which these two questions of absolute and relative miracle are solved, must depend the character of revelation and the meaning assigned to the word. If the idea of absolute miracle is maintained, revelation will be regarded as knowledge imparted in an extraordinary manner implying a violation of natural laws; although after such promulgation it may be left to work in accordance with the ordinary course of things. On the hypothesis of relative or notional miracle, it will appear an unbroken and continuous process, coextensive with the existence of mankind from its beginning to its close, a work of which some part was accomplished when language became capable of expressing the several relationships of family life, and of which a higher stage was reached, when, possibly in a much later age, 'the conception of a Creator, a Ruler, a Father of man, when the name of God was for the first time uttered in this world.' (Max Müller, *Lectures on Language*.) [MONOTHEISM; POLYTHEISM; SUPERSTITION.]

The well-known argument of Hume, on the inherent incredibility of all miracles grounded on the continuity of nature, has been turned by Mr. Mozley, in the work already cited, against those who use it. In his opinion, no ground of reason can be assigned for the expectation 'that any part of the course of nature will the *next* moment be like what it has been up to this moment,' the belief that it will so continue having 'no more producible reason for it than a speculation of fancy.' The inductive principle, he asserts, stands on no surer basis; and hence he argues that the ground is gone upon which it could be maintained that miracles, as opposed to the order of nature, were opposed to reason. His conclusion is that 'when there is nothing on the side of reason opposed to the expectation of likeness, as is the case commonly, we follow it absolutely. But supposing there should arise a call of reason to us to believe what is opposite to it; supposing there is the evidence of testimony, which is an appeal to our proper reason, that an event has taken place which is opposed to this impression; it is evident then that our reason must prevail in the encounter, i.e. that if there is on one side positive evidence, the antecedent counter-expectation must give way.'

To this argument it has been objected, by those who consider it 'unanswerable as an argumentum ad hominem,' that it leaves to miracles, as such, no value whatever. 'If we dissever the connection between cause and effect, we denude the miracle of all meaning. A miracle has only meaning on the supposition of noumenal agency or real causation; it is on this supposition alone that we can draw the inference

of a supernatural cause.' Hence it is affirmed by such objectors that 'Mr. Mozley has only developed in one direction the inherent scepticism of the empirical philosophy.' (*Christian Remembrancer*, October 1866, p. 509.) From another point of view, Mr. Mozley's argument takes us from the ground of philosophy to that of history; and by those who take this ground it has been asserted that, where an alleged event breaks a continuity universal in all scientific experience, the evidence for that event must be adequate both in amount and quality, and that no valid argument can be raised on testimony found in books of which the historical character is not thoroughly established. The argument for alleged miraculous events is thus brought back to the general credibility of the narratives which relate those events.

Supersedeas (Lat.). In Law, a writ that lies to stay various ordinary proceedings.

Superstition (Lat. superstitio; according to some, *the standing still over a thing* in admiration or awe, while others take the word to mean *a clinging to old ground*). Superstition may perhaps be ultimately defined as belief not in accordance with facts. This is, obviously, an essential definition which leaves out of sight certain characteristic features which mark the superstitious man in all times and countries. It is, of course, possible that the seeds of superstition involved in erroneous belief may, from want of a congenial soil, fail to produce any fruit, nor can all erroneous opinions be regarded as furnishing a basis for superstitious practice. A man who should believe that some birds have four legs would entertain an opinion not in accordance with known facts, but he would not be considered superstitious, unless he added to this the notion that birds with four legs appeared from time to time to plague men, and that under certain circumstances or in certain places he might himself suffer from their attacks. Hence superstition has sometimes been said to consist in a physical dread of the unknown; and undoubtedly the passion of terror is largely fed by superstitious beliefs in general. But such an explanation fails apparently to account for all the phenomena, and the affection of terror is at best a consequence and not the cause of the superstition. The beings which a superstitious man dreads may be, in the vast majority of instances, repulsive or terrific; and hence he may be more taken up with efforts to avert their wrath than to secure a kindness which he thinks them incapable of feeling. But the man who holds, as the Greek held, that every tree, stream, or glen had its nymph, and that these nymphs were beautiful and benignant beings, whose kindly offices men might secure by paying them certain honours, is not less a superstitious man because his superstition may not exhibit the characteristic of terror. Nor can the dread which some superstitious men feel be always considered in strictness of speech a dread of the unknown. The most degrading superstitions spring out of the belief of men who have no doubt whatever as to the absolute accuracy of the map which they draw of the unseen world, and who consider themselves not less possessed of a real knowledge of the nature and habits of angels, demons, fairies, dragons, and other beings, than that which we suppose to be furnished by the maps of the Ordnance Survey.

It would seem, then, that, although belief not in accordance with fact furnishes the basis of superstition, such belief cannot issue in superstitious practice, until or unless the thing which is the object of belief is regarded as capable of injuring or helping the thinker: and inasmuch as superstitious action may spring from notions which in themselves seem most unlikely to lead to such a result, every question connected with superstitious practice becomes ultimately a question of fact. A train of the closest and most consistent reasoning may be deduced from the assumed existence of chimæras, but unless it has been proved that chimæras do in fact exist, the whole argument is fallacious, and all who receive it involve themselves in a belief which may at any time issue in superstitious practice. From this it seems to follow that the deductive method of science is not free from the element of superstition. As long as the cosmos was interpreted, and the motions of the planets explained according to some arbitrary hypothesis, an outgrowth of superstition, based on the science, was kept in abeyance only by the nature of the hypothesis. If the latter professed to account for a long series of complicated phenomena on the ground of observed sequences, it approached more nearly the character of a true science, and in the same degree was removed from superstition. We may safely assert the impossibility of basing any superstitious belief on the Heliocentric System of Aristarchus of Samos. But the hypotheses of many of his predecessors, and of some among his contemporaries and successors, furnished a fruitful source of false ideas, from which might issue at any time the most absurd or revolting superstitions. The idea of Heracleitus that the stars were fed by exhalations from the earth, that the sun was a bowl not wider than a man's foot; the notion of Xenophanes that the stars were fiery clouds, lit at night like coals and put out in the morning, and that the sun, resembling these in substance, was likewise renewed every day; could by no possibility lead to any wholesome result, and might be followed by the worst extravagances. It would be necessary only to embody in human shape the being whose office it was to light the stars at night and put them out in the morning, in order at once to introduce a system of magical rites which should appease his anger or win his favour.

The superstitious element, whether in belief or practice, lies, therefore, not in the chain of arguments which may be adduced in their favour, but in some primary hypothesis which is not in accordance with facts. If it be granted or proved that there are devils, and they act in a particular way, there is nothing at all superstitious in the conclusion that they

carried witches through the air to diabolical festivals in the Harz mountains, or in the reasoning which from these premisses established the prevalence of WITCHCRAFT as well as the enormity of the sin. [RATIONALISM.] The hypothesis being accepted, the reasoning might be indefinitely forcible, and the gravest and wisest of judges admitted that they found themselves altogether unable to resist it. The assertion that there is a Great First Cause for all things, and that this Cause is Mind, is altogether in accordance with every fact or phenomenon known to us, and hence this conviction is not only free from the slightest character of superstition, but is the strongest and ultimately the only safeguard against it. In proportion as we recede from this conviction, and from all that is by direct reasoning involved in it, we open the doors to all conceivable superstition; nor can we affect to treat with mere contempt the reasoning which underlies the horrible instances of mediæval superstition which Hallam has collected, *Middle Ages*, ch. ix. part i. The anecdotes there told of effects produced by the prayers and operation of the Virgin Mary are at the worst extravagant results from an unproved and therefore unwarranted hypothesis.

It follows, finally, that every belief and every practice not based on, or not in accordance with, actual fact, must have an injurious effect on the mental and moral state of the thinker or actor. How great may be the amount of mischief so produced, and how far it may check the growth of all literature, art, and science, the reader may gather from the chapter of Hallam already cited.

Of the other aspects of the subject, some have been noticed in the articles on MONOTHEISM, MYTHOLOGY, POLYTHEISM, and RATIONALISM.

Supertonic (Lat. super, *above*; tonus, *a tone*). In Music, the second above the keynote.

Supination (Lat. supinatio, *a bending back*). The art of turning the palm of the hand upwards by rotating the radius upon the ulna.

Supines (Lat. supinus, *on the back*). In Grammar, a name given to two cases of verbal substantives in Latin, the active supine being the accusative, and the passive (the introduction of which is unnecessary) being the ablative. The former has the same power of government with the verb to which it belongs, and it expresses a purpose, as *ire spectatum monumenta regis* (Hor. *Od.* i. 2).

Supplement (Lat. supplementum). In Geometry, the supplement of an arc is its defect from a semi-circumference; the supplement of an angle is its defect from two right angles. Two *supplemental angles* are together equal to right angles.

SUPPLEMENT. In Literature, an addition made to any work or treatise, in the view of rendering it more complete.

Supplemental Triangles. [SPHERICS.]

Supply (Lat. suppleo, *I fill up*). In Finance, the appropriation of all the sums voted annually by parliament in a committee of the whole house is known by this name. The practice dates, in effect, from the Revolution, and is looked on as one of those safeguards by which the administration is kept in check by the votes of parliament.

The known or probable amount of the different branches of the year's expenses is stated to the House of Commons in a committee of supply by the Chancellor of the Exchequer, and after the several items have been voted by the committee they are formally granted by an Act of Parliament, called the Appropriation Bill. The granting of the annual supplies is a peculiar privilege of the House of Commons, which never permits any alteration or amendment (except merely verbal) to be made by the House of Lords in the bills passed for this purpose.

SUPPLY. In Political Economy, the response to demand for commodities, the second term in the equation of exchange. Demand precedes supply, and may exist in a very urgent degree without it. It is often the case that the persons requiring supply are unable to perform their part in the exchange, either because they do not produce, or because that which they produce is not itself in demand. Such cases are not indeed objects of economical enquiry, since the demand is not effectual. Or, on the other hand, the demand may be urgent, and the elements contributing to an exchange may be abundantly present, but the supply may be wanting, because some of the conditions, under which alone supply is accorded, are deficient. But as in industrial communities the fulfilment of supply, by importation from foreign sources of such articles as are not produced by the community, or are not produced so cheaply and abundantly, is of paramount importance, it may be to the purpose to state and explain the conditions under which supply is forthcoming in sufficient amounts to meet the demand created for it.

First, then, capital must exist in sufficient abundance for the purpose of answering demand. Commodities are exchanged against commodities, and objects of value are appropriated by labour. But any natural condition of supply may be present, and even labour itself may be abundant; but in the absence of the capital necessary to set labour in motion, no response may be made to the demand. Now, in countries where but little industrial activity exists, and but scanty accumulations of capital are made, or where foreign capital, either by reason of ignorance or distrust cannot be imported, it may be very difficult to divert any portion of existing capital towards the supply of a new demand, however urgent the demand may be. For instance, during the last four years the demand for raw cotton has been exceedingly great. The prices of this material rose in the case of the better qualities to four or five times their common rate. There is, perhaps, no article the geographical range of which is wider than that of cotton. It can be

grown from the equator, upwards and downwards, to a considerable portion of the temperate zone. It is, moreover (at least some of its best species are), an annual plant. The profit on the cultivation of the crop would have been enormous. But though it is clear that to some extent the cultivation of cotton was checked by the general error into which European governments fell as to the resources of the Southern Confederacy and as to the perseverance of the North, much, it cannot be doubted, of this incapacity to meet the demand created was due to the difficulty of finding capital for the office.

Next, the area of supply must be sufficiently wide, not only possibly but actually. By far the larger portion of the cotton supply was derived, as is well known, from the Southern States of the American Union. A very small quantity came from the rest of the American continent; and an amount, tolerably large, but of an inferior staple, was imported from Egypt and India. Now, when the supply of any great necessary of life or of industry is accidentally produced from a narrow area, the importation is liable to two interruptions; those, namely, of deficient crops, and of the enforced cessation of commercial intercourse. Cotton, like any other kind of agricultural produce, is liable to injury from weather, and to the ravages of insects, and from time to time both these causes have operated to diminish and even almost to annihilate the supply from America. Again, as we have lately understood, it is possible to create and maintain so strict a blockade over a great line of coast, as to reduce the exports of bulky goods to a minimum. We do not, of course, know what amount was exported by blockade runners, but we are certain that it was wholly insufficient to affect prices or to alleviate the scarcity and distress consequent upon the deficiency. If, however, the area of supply had been wide, no such inconvenience could have happened. The price of the raw material might have risen considerably, if a large contributory had suddenly ceased to export, but the void would have been rapidly filled up. As far as regards political contingencies, we may perhaps anticipate that we are so far advanced in civilisation as never for the future to go to war with the whole world, as we almost did during the later years of the great continental war, when, in addition to our European enemies, we were at variance with the United States. The most immediate and obvious illustration of the advantage of having a wide area for supply is cotton, but that of corn is still more important, and, happily, is less liable to interruption on a large scale, than any other commodity. While corn is produced in many regions, and is freely imported, the deficiency of the season in one locality may be compensated by increased production in another, dearths being almost always of limited extent. For instance, to take an example from remote times, the years 1315–16 were times of absolute famine in England, but if Cibrario's figures are to be trusted, of plenty in Northern Italy. Similarly, the supply of wheat in the harvest of 1863 was exceedingly scanty in England, but singularly abundant in the western states of America. In connection with these facts, it may be mentioned, that there is scarcely any commodity of importance which is produced in single localities, and which, therefore, may appear open to an export duty, while it is quite certain that there is no necessary of life which is produced in one country only, or under one political régime.

Next, the producer must be secure, ordinarily speaking, of such a market as will compensate him for the cost of production, according to the ordinary rate of profit ruling in the producing country. An uncertain or a fluctuating market is the bane of supply. Thus, for instance, during the existence of the corn laws, it was impossible for the foreign producer to determine whether the produce of any year would be admitted to the English market. A maximum price was fixed at which corn could be imported, and when the price fell below that amount a varying duty was levied. Under such a system no one could anticipate whether, in case he cultivated or exported grain, he might be sure of any sale in England. Hence in years of large foreign production, grain was accumulated in bonded warehouses, the most expensive and the most unfit granary conceivable, to be often destroyed and wasted. Under such circumstances it was not likely that a trade in foreign corn could flourish, or that the English market should be at all supplied.

Lastly, the means of transit or carriage must be provided. We have already [RAILROADS] adverted to the economical effects of cheap and efficient land carriage, and shown how greatly these means reduce the cost of articles to the consumer, and thereupon create an extended market to the producer. The same reasoning applies to cheap and efficient carriage by sea. Scientific observation may result in conclusions involving the largest benefits to mankind. To take an example: In 1770, Franklin, by means of information obtained from one Folger, a Nantucket whaler, as to the course of the Gulf Stream, obtained a rude chart of its geographical position. Folger had noted the stream because no whales are ever found in its warmer waters, but always on its margin. Before this discovery the voyage to the northern part of the American colonies was always long, hazardous, and expensive, and in winter-time almost impracticable. For political reasons Franklin concealed his discovery till 1790. The effect of the publication which he made at that date was to change completely the character of the trade, and to transfer European traffic from Charleston to the northern ports. Captain Maury, whose work on the *Physical Geography of the Sea* is, apart from its scientific merits, of profound economical interest, tells us that the result of meteorological researches is to shorten long sea voyages by 30 per cent. Ten years ago, it

was estimated that the economy of these discoveries and directions might, from a calculation of the tonnage-despatched from the United States to California, Australia, and Rio Janeiro alone, be estimated at 2½ millions of dollars. It is almost impossible to do more than guess at the general saving to the mercantile world, but it will be quite clear that any economy in carriage and transit which opens a wider field of supply is a permanent benefit to mankind, and removes to a more and more distant point the cessation of those advantages which the human race procures from the peaceful and civilising operation of reciprocal trade.

To advert, in conclusion, to the supply of cotton. The manufacturers, in an association formed for the purpose of extending the area of growth and facilitating its carriage, have complained greatly of the land system of India, and the hindrance which the traditions of the Indian fiscal system put in the way of employing capital for the production of cotton. We cannot now enter into these questions, which may be found indirectly answered under the heads RYOT; TAXATION; TITHE; but the association was certainly justified in severely criticising the supineness of the administration in leaving India without railroads, without an efficient banking system, and even without navigable rivers and canals. From a military and fiscal point of view, the neglect of such administrative duties was sufficiently reprehensible, but in an economical one far more so. There is no justification of the Indian empire, except that of necessity and duty; and it is surely a matter of the highest obligation that a European administration should not fall short of the ancient rule in promoting great industrial undertakings: it should rather be far superior to that which it has supplanted.

Support, Points of. In Architecture. [POINTS OF SUPPORT.]

Supporter. In Shipbuilding, a knee-piece of oak firmly bolted under the cat-head, to reinforce it when sustaining the weight of the anchor.

Supporters. In Heraldry, figures placed on each side of the scroll, as if to support it. In English heraldry, supporters are granted only to noblemen, or to knights bannerets, by favour of the sovereign. The origin of supporters is said to have been this: some days prior to a tournament, to prevent the appearance of unqualified persons, every knight desirous of entering the lists was required to hang up his shield upon which his arms were emblazoned, in the place assigned by the appointer of the tournament for examination by the heralds. The shields thus exhibited were guarded by the servants of their respective knights, their livery disguised by dresses representing savages, Moors, griffins, lions, &c. 'In England supporters are not granted without the express command of the sovereign; but in Scotland "Lord Lion" enjoys this privilege. They are not borne by spiritual peers.' (Boutell's *Heraldry*.)

Supposed Bass. In Music, the bass of a chord when it is not the root of the common chord or harmonic triad. It is also sometimes called the inversion of the accompanying chord.

Supposition. In Music, the use of two successive notes of equal value as to time, one of which being a discord supposes the other to be a concord. The harmony, though by rule falling on the accented part of the bar, and free from discords, requires their proper preparation and resolution; and they are called *passing notes*. Discords on the unaccented part of the measure are allowable by conjoint degrees, and it is then not required that the harmony should be so complete on the accented part. This transient use of discords followed by concords is what we, after the French, call *supposition*, of which there are several kinds.

Suppository (Lat. subpono, *I place under*). A pill or bolus introduced into the rectum, where it gradually dissolves. Opium is sometimes usefully applied in this way to allay irritation of the bladder and the neighbouring parts.

Suppression (Lat. suppressio, *a keeping down*). A figure in Grammar is sometimes so called by which words are omitted in a sentence which are nevertheless to be understood as necessary to a perfect construction: as, for instance, in most languages, the repetition of a noun is avoided where it is coupled with a pronoun in one branch of the proposition; e.g. 'This (horse) is my horse,' or 'This horse is mine' (horse). [ELLIPSIS.]

Suppuration (Lat. subpuratio, *an abscess*). The process by which pus or matter is formed.

Supralapsarians (Lat. supra, *above*, and lapsus, *a fall*). In Theology, those who assert that the fall of Adam, with all its consequences, was predestinated from all eternity. [CALVINISTS.]

Supranaturalists (Lat. supra; natura, *nature*). A name given of late years to the middle party among the divines of Germany, to distinguish them from the *Rationalists*, who exclude all supernatural manifestations from religion; and from the Evangelical party, whose tenets are of a more strict description. Thus many of the supranaturalists appear to have adopted the system of accommodation (as it is termed) in religious matters, so far as to explain away the doctrine of original sin, and other tenets commonly considered fundamental: others approximate to what are generally regarded as orthodox Protestant opinions.

Suprarenal Bodies (Lat. supra, and renes, *the kidneys*). In Anatomy, the flattened bodies situated on the upper part of the kidneys in man, and at the fore part in brutes: they are well supplied with blood-vessels and nerves, and are composed principally of simple or closed vesicles, resembling the secreting glands, except that they have no ducts. They are of disproportionately large size in the fœtal state in man and quadrumana.

Supremacy, Oath of. An oath denying the supremacy of the pope in ecclesiastical or temporal affairs in England, which by many statutes was required to be taken, along with the oath of allegiance, by persons who wished to qualify themselves for office, &c. In 1858, however, a new form of oath was substituted for the three oaths of allegiance, supremacy, and abjuration (21 & 22 Vict. c. 48), and a still simpler form was provided for the use of members of both houses of parliament on taking their seats, by the Parliamentary Oaths Act 1866.

Supremacy, Papal. [PAPACY.]

Supremacy, Royal. This term, as applied to the sovereign power in a monarchy, would appear to denote civil no less than ecclesiastical authority. In practice, however, while the civil authority of the sovereign power has never been questioned, its ecclesiastical authority has been often impugned, and the phrase in question has consequently been applied almost exclusively to the supremacy of the crown over ecclesiastical causes and persons.

There appears to be no doubt that the supremacy of the crown in ecclesiastical affairs was both theoretically held and practically asserted in the early ages of English history. In the reign of William the Conqueror the court of the bishop was separated from the hundred court by a royal charter granted under the advice of the great ecclesiastical and civil personages of the realm. In 1157 a dispute between the bishop of Chichester and the monks of Battle Abbey was decided by the king in council. The practice of appealing to Rome was first introduced into this country in the reign of Stephen, by the legate Henry of Blois, bishop of Winchester, but the ancient course of justice seems to have been restored under Henry II. by the Constitutions of Clarendon. The pope, however, still asserted and exercised a real though ill-defined authority over the church of England as an integral part of the Western church [PAPACY], and appeals to Rome once more became common, although they were never expressly sanctioned by the laws of England, and although the Statutes of Provisors and Præmunire [PRÆMUNIRE; PROVISORS] enjoin heavy penalties against those who 'do sue in the court of any other in derogation of the regality of our lord the king' (16 Rich. II. c. 5).

At the Reformation, the independence of the crown was again asserted. Appeals to Rome were prohibited by the Act of Appeals (24 Hen. VIII. c. 19) and the Act of Submission (25 Hen. VIII. c. 19), and by the latter statute the appellate jurisdiction in ecclesiastical causes was expressly vested in the crown, where, except during the reign of Mary Tudor, it has ever since remained.

The royal supremacy was declared by 26 Hen. VIII. c. 1; and the present Act of Supremacy (1 Eliz. c. 1, 'An Act for restoring to the crown the ancient jurisdiction over the state ecclesiastical and spiritual, and abolishing all foreign power repugnant to the same') provides that no foreign prince, prelate, or potentate, spiritual or temporal, shall exercise any manner of power, jurisdiction, or privilege, spiritual or ecclesiastical, within the realm or the queen's dominions; and, next, that such jurisdictions and privileges spiritual and ecclesiastical, as by any spiritual or ecclesiastical power had been or might then be lawfully exercised or used for visitation and correction of the ecclesiastical state and persons, shall for ever be united and annexed to the imperial crown of the realm.

It was not, however, till after the Restoration that the regular course of appeals in ecclesiastical suits became established in its modern form; the jurisdiction of the crown was before that period exercised for the most part by extraordinary royal commissions, culminating in the famous Court of High Commission, which was established in 1583 and lasted till 1640. Subsequently to the Restoration, the practice was for the appellant from the ecclesiastical court to petition the Lord Chancellor, praying that a commission of appeal might issue under the great seal, and be directed to judges delegates to be named at his discretion. A fresh commission issued in each case; but as the delegates were selected from a permanent list, the tribunal acquired the name of the High Court of Delegates. The delegates selected usually consisted of doctors of civil law and common law judges: it was formerly usual to add some of the bishops, but this practice was gradually disused. The High Court of Delegates was abolished in 1832, and its jurisdiction transferred to the king in council. In the following year it was enacted (stat. 3 & 4 Wm. IV. c. 41) that all appeals to the privy council should be referred to a judicial committee of the council, who should report thereon to the sovereign. This committee, therefore, now constitutes the supreme court of appeal in matters ecclesiastical. It consists of the present and past holders of certain high judicial offices, together with two privy councillors nominated by the crown, and, in cases under the Church Discipline Act (3 & 4 Vict. c. 86) the prelates who are privy councillors. The lord president summons the members of the committee who sit on each occasion. (Brodrick and Freemantle, *Ecclesiastical Judgments of the Privy Council.*)

The right of nomination to archbishoprics and bishoprics forms a branch of the royal supremacy, both as anciently understood and as now exercised. 'Election,' says Blackstone (1 *Comm.* 377), 'was in very early times the usual mode of elevation to the episcopal chair throughout all Christendom, and this was promiscuously performed by the laity as well as the clergy, till at length, it becoming tumultuous, the emperors and other sovereigns of the respective kingdoms of Europe took the appointment in some degree into their own hands, by reserving to themselves the right

of confirming these elections, and of granting investiture of the temporalities (which now began almost universally to be annexed to this spiritual dignity), without which confirmation and investiture the elected bishop could neither be consecrated nor receive any secular profits. This right was acknowledged in the emperor Charlemagne, A. D. 773, by Pope Hadrian I., and the council of Lateran, and universally exercised by other Christian princes; but the policy of the court of Rome at the same time began by degrees to exclude the laity from any share in these elections, and to confine them wholly to the clergy, which at length was completely effected, the mere form of election appearing to the people to be a thing of little consequence, while the crown was in possession of an absolute negative, which was almost equivalent to a direct right of nomination. Hence, the right of appointing to bishoprics is said to have been in the crown of England (as well as other kingdoms in Europe) even in the Saxon times, because the rights of confirmation and investiture were in effect (though not in form) a right of complete donation. But when, by length of time, the custom of making elections by the clergy only was fully established, the popes began to except to the usual method of granting these investitures, which was *per annulum et baculum*, by the prince's delivering to the prelate a ring and pastoral staff or crosier, pretending that this was an encroachment on the church's authority, and an attempt by these symbols to confer a spiritual jurisdiction.'

It is quite beyond the limits of these pages to trace the history of the contest which long prevailed between the popes and the temporal powers of Europe with respect to ecclesiastical investitures. Eventually, the question ended in a compromise, by which the sovereign received only homage from the bishops for their temporalities, instead of investing them with the ring and crosier, retaining nevertheless the substantial power of nomination.

In England, however, King John surrendered by charter to the cathedral chapters the free right of electing their bishops, reserving to the crown only the custody of the temporalities during the vacancy, the form of granting a license to elect (on refusal whereof the electors might proceed without it), and the right of approbation afterwards, which was not to be denied without a reasonable and lawful cause. These privileges were confirmed by Magna Charta, and continued till the Reformation. The bishops elect were confirmed by the archbishop from the charter of King John to the reign of Edward III., after which period the pope superseded the archbishop.

At the Reformation, the right of nomination was again vested in the crown, and a curious system of forms established, which remains to the present time, it being enacted (25 Hen. VIII. c. 20) that on the avoidance of a bishopric the king may send the dean and chapter his license to proceed to election (congé d'élire), which is to be accompanied by a *letter missive* from the king containing the name of the person he would have them elect. If the election be delayed above twelve days, the nomination lapses directly to the crown. The person elected is confirmed, invested, and consecrated by the archbishop; but it was decided in 1848, in the celebrated case of Dr. Hampden, that the function of the archbishop is ministerial only, and that he has no power to take cognisance of any objections to the person presented to him.

Previously to the year 1850, the Roman Catholics in England had for many years been under the authority of vicars apostolic appointed by the pope. These were, in fact, bishops; but in order to avoid the jealousy of the civil power their titles were taken from places abroad, and the word *district* was used instead of *diocese*, to express their local jurisdiction, submission to which was, of course, voluntary only. In Ireland and the colonies, however, the Roman prelates had long assumed the episcopal title. In the year 1850 the pope issued letters apostolic dividing England into formal dioceses, and appointing a bishop or archbishop to each. This measure (commonly known as the *papal aggression*) caused great excitement at the time, and an Act was passed (14 & 15 Vict. c. 60) imposing penalties on persons assuming the title of archbishop or bishop of any place unless authorised by law. The Act, however, can only be enforced with the consent of the Attorney-General, and it has been quietly allowed to become a dead letter, no prosecution having been instituted under it, although the English Roman Catholic bishops habitually use territorial titles.

The royal supremacy has been considered to extend to the colonies, and numerous bishoprics (endowed for the most part from private sources) have been established there by the crown under letters patent, and the crown has in the same manner appointed bishops to the different dioceses, some of whom have been invested with a metropolitan or superior jurisdiction. It has, however, been recently decided by the Privy council in Mr. Long's case (1863) and the Natal case (1865) that letters patent issued by the crown after the establishment of a constitutional government in any colony are ineffectual to create therein any legal diocese, subject to coercive ecclesiastical jurisdiction, or any ecclesiastical corporation whose status, rights, and authorities the colony can be required to recognise. 'The church of England,' Lord Kingsdown said, in giving judgment in Long's case, 'in places where there is no church established by law, is in the same situation with any other religious body, in no better but in no worse position, and the members may adopt, as the members of any other communion may adopt, rules for enforcing discipline within their body, which will be binding on those who expressly or by implication have assented to them.' (See further the case of Colenso *v.* Gladstone, decided in Chancery, Nov. 1866.)

Sura. The Arabic name for the chapters of the Koran. These chapters were, it is asserted, given forth sometimes as a whole, sometimes in driblets, and often in single verses. Such driblets Mohammed, it is said, directed his amanuensis to enter 'in the sura which treated of such and such a subject.' If this tradition be authentic, it would indicate that Mohammed wished the Koran to be arranged according to its matter, and not chronologically; and hence the difficulty of assigning dates to each sura or portion of a sura is indefinitely increased. The arrangement is made, therefore, in the absence of other proof, to rest mainly on internal evidence, the various phases in his life, so far as we can be said to have any knowledge of it, being illustrated by the various chapters of the Koran. This perilous task has been attempted by many writers; with more than average success by Mr. Muir, in his *Life of Mahomet*, to which the reader is referred for a review of all the literature relating to the Prophet of Islam. According to Mr. Muir's canon, the earliest suras are vehement and impetuous fragments, while in those of a later date the style becomes calmer and more uniform; with the decay of really sincere and earnest feeling, the suras become more lengthy and elaborate; and the theory of inspiration is more fully developed. Thus, the passages in which reverence is claimed for the Koran, by ascribing to it not Divine inspiration only, but a heavenly original, belong to a later time than those in which the prophet speaks of himself simply as declaring the will of the Most High. It is obvious that with such uncertain materials the conclusions of independent writers must be more or less antagonistic; and the manipulators of the Koran have not escaped the criticism which commonly falls to the lot of those who attempt to determine the chronological order of facts, for which we have not adequate evidence in contemporary documents.

Surbase (Fr.). In Architecture, the upper base of a room, or rather the cornice of the dado.

Surcharged or Overcharged Mine. In Military Mining, a mine loaded with a very great charge of powder. It is sometimes called a *globe of compression*.

Surcoat (Fr. sur, *over*, and Eng. coat). A garment, generally of silk, forming part of the knightly equipment of the middle ages, from the thirteenth century. [CYCLAS; JUPON.] It was worn over the body armour, and was originally designed to defend the armour from wet.

> Gay gownus of grene
> To hold thayre armur clene
> And were· hitte fro the wette.
> *The Avowynge of King Arther*, stanza 39.

Surd (Lat. surdus, *dull*, *silent*). In Arithmetic and Algebra, a magnitude which is inexpressible by rational numbers. Thus, the square root of 2, the cube root of 3, &c., are numbers which cannot be expressed exactly in the ordinary notation, and are represented by prefixing the radical signs indicating the operation, viz. $\sqrt{2}$, $\sqrt[3]{3}$. Such quantities are otherwise called *irrational* or *incommensurable*.

Surf. [WAVE.]

Surface (Fr.; Lat. superficies). In Geometry, the boundary of a solid, or that which has length and breadth, but no thickness. A surface may be conceived to be generated by the motion of a straight or curved line, just as the latter may be generated by the motion of a point. A surface is said to be *plane* when a right line can be applied to it everywhere and in every direction: in other cases it is called a *curved surface*. Surfaces generated by the motion of a right line are called RULED SURFACES, in which family are included DEVELOPABLE SURFACES and SKEW SURFACES. A curve by rotating around an axis generates a *surface of revolution*. [REVOLUTION.] Several other distinctive names are given to surfaces according to their peculiar properties or modes of generation; these being noticed in their proper places, we have only to add here that the most general classification is that into *orders* and *classes*. The *order* of a surface is the number of points, real or imaginary, in which it is cut by any right line; in other words, the degree of the equation which is satisfied by the co-ordinates of its several points. By the *class* of a surface is meant the number of its tangent planes which pass through any given line. Surfaces of the second order are also of the second class; but in general order and class are different. Surfaces whose equations involve transcendental functions of the co-ordinates are termed *transcendental*, to distinguish them from *algebraic surfaces*, to which alone the term *order* can be applied. One of the most complete English treatises on surfaces is contained in Salmon's *Analytical Geometry of Three Dimensions*, Dublin, 1865.

Surface Condensation. A method of condensing the steam discharged from an engine by means of cold metallic surfaces like those of a still, to the end that the water thus recovered may be used again to feed the boiler. The benefit of this practice in the case of steam vessels is, that the boiler being fed with pure distilled water, instead of with salt water from the sea, the risks of salting the boiler are prevented, and higher pressures of steam may be used with safety. Common sea water deposits sulphate of lime without undergoing concentration when the temperature is increased to a point answering to a pressure of 40lbs. per square inch; and if scale be suffered to accumulate on the flues or furnaces of a boiler maintaining a high pressure, the flues may become red hot and collapse, or, in other words, the boiler may burst. Now, as a high pressure of steam is necessary to the efficient application of the principle of expansion, and as fresh water in the boilers is the necessary antecedent of high pressures, the principle of surface condensation acquires great importance in steam navigation, although the

benefits of the system have not yet been fully developed. The condensation is usually effected by discharging the steam against a faggot of pipes through which cold water is made to circulate by a pump. The pipes at their ends pass through a metal plate in which they are made tight either by a small stuffing box and screw at each, by the application of a perforated sheet of Indian-rubber pressed down by another perforated plate above, or by the interposition of a ferrule of compressed pine between each pipe and the plate; the water swells the wood and makes the joint tight. The pipes are usually made of copper or brass, and should be tinned externally to prevent galvanic action on the boiler. [STEAM NAVIGATION.]

Surgeon. In the Army, the officers of the medical department are classed as follows: Director-general, who ranks as a major general; inspector-general, as brigadier-general, or, after three years' service, or in the field, as major-general; deputy inspector-general, as lieutenant-colonel—after five years' service, as colonel; surgeon-major, as lieutenant-colonel, but junior of the rank; surgeon, as major; assistant-surgeon, as lieutenant—after six years' service, as captain. Each regiment of cavalry and battalion of infantry has a surgeon and an assistant-surgeon. Staff-surgeons and assistant-surgeons are usually employed at the general and garrison hospitals at home and abroad.

Surgeon, Naval. An important officer in the economy of a ship. In the Royal Navy there are the following grades: inspector-general of hospitals and fleets, deputy-inspector, staff-surgeon, surgeon, assistant-surgeon. The whole service is organised under a director-general, who sits at the Admiralty. In the merchant service no well-appointed ship of any size above a mere coaster or schooner sails without a surgeon.

Surgery (Gr. χειρουργία, *a working by hand, the practice of an art*). This word, in its modern acceptation, may be defined as the practical application of medical science, in the use of all mechanical or instrumental means, for the removal of diseases and the relief of human suffering.

If it be true that man is impelled by an instinctive impulse to seek for some natural remedy for his bodily disorders, the practice of medicine must for some time have existed before the dawn even of the rudest deductive theories. The wish to cause vomiting in order to relieve nausea would impel the sufferer to seek for something which would act as an emetic, and the discovery of such a thing might be either imparted to his fellow-men or kept secret as a means both of profit and power. In matter of fact, the knowledge of herbs and simples so acquired seems in all countries to have been confined to a small class, which in the sequel assumed all the powers of a caste, and was generally identical with the priesthood. In this, which may be termed the sacerdotal stage of medicine, the hierarchy, possessed of a certain knowledge not shared by the great body of the people, and having no interests which might be hurt by the extension of that knowledge, affords a valuable aid to the growth of medical science. But the observation that remedies act in a given way, being effective in some cases and useless in others, leads to the idea of an orderly and regular causation, and the theories of the miraculous or supernatural characters of diseases begin to lose their original power and charm; and although the student of medicine may try to avert opposition by declaring that all causes with all their consequences are equally divine, an instinctive feeling warns the priestly caste that the advance of such notions must insure their downfall, and leads them to an uncompromising antagonism.

This speculative or sceptical stage of the science, if summarily arrested, will be followed by an effete stagnation, like that which followed the extinction of Saracenic science in Spain: but if the efforts for repression fail, the growth of a genuine scientific school has for its result a large accumulation of observations, and of knowledge derived from experiment, which may again bring it into collision with theologians and deductive reasoners.

These several stages may be traced with more or less exactness in the history of medical science amongst the Greeks and Romans, in Egypt and Spain, in mediæval Europe, in the Eastern world, and in the modern states of Europe and America. The Ayur Veda of the Hindus embodied the medical knowledge of the priestly caste in a form analogous to that of the Egyptian priesthood, and as this system has retained its hold to the present day their medical science exhibits still the features which marked it two or three thousand years ago.

In the Greek legends, the tales of Cheiron and Asklepios (Æsculapius), of Heracles, Podaleirion, and Melampus, illustrate that mythical era of medicine to which SANCHUNIATHON and his alleged writings may be assigned. The remedies applied by the school which assumed the name of Asklepios were, as we might expect, altogether empirical, and their unscientific character called forth the Aristophanic satire, which represented the Asklepiadæ as stealing during the night the offerings of their dupes. The Pythagoræan schools (whether Pythagoras be mythical or historical) worked to better purpose, and came accordingly into conflict with the traditional dogmas of ruling classes. The men who on recovery from sickness put up a votive tablet to some deified hero, whom they regarded as their healer, could not well tolerate a system which applied a specific remedy to a specific evil in the anticipation of a merely natural result.

That Greek medicine had reached its speculative or sceptical stage is abundantly attested by the doctrines of Hippocrates, who 'treated all phenomena as at once both divine and scientifically determinable. (Grote, *History of Greece*, part i. ch. xvi.) Of all diseases he affirmed that 'none is more divine or more

human than another, but all are on the same footing, and all divine; nevertheless, each of them has its own physical conditions, and not one occurs without such physical conditions.' It is obvious that one who so spoke might profess to start with or uphold some deductive theory, but his science pointed wholly to observation and experiment, and took no cognisance of any causes beyond those which might be ascertained by human industry and research. Hence Hippocrates necessarily made light of all hypotheses which connected the study of medicine with astronomical phenomena, and insisted that medicine should be determined by and bear reference to its own end, i. e. to the nature of man, as ascertainable by practical examination. This method marks especially the Hippocratic treatise on Climate as affecting the developement of the human race, and the basis of his Humoral Pathology, which retained its hold on the medical schools of Europe for more than 2,000 years.

Medical science, checked in Greece by the disorders which followed the fall of Athens, received a fresh impulse in the schools of Alexandria. These schools were especially distinguished for their anatomical researches. By dissection and experiment they laid the foundation of scientific anatomy and physiology; and the advance made was so great that, while Aristotle hardly knew that there were nerves, Herophilus was enabled to demonstrate the functions of both the motor and sensitive nerves.

While medical science was thus advancing in Egypt, at Rome it had scarcely taken root, nor can the schools which sprang up in the later days of the republic and after the establishment of the empire be strictly considered Roman. They were founded by Greek physicians; and the Romans who, like Celsus, became most eminent in them, whether belonging to the Eclectic or to other sects, adopted Greek theories, or reasoned from Greek axioms. To Celsus medical science is indebted for a great advance, not only in pharmacy, but also in surgical knowledge. Roman medicine reached its culminating point when, under Marcus Aurelius, Galen sojourned in Rome. The degree to which deductive methods still influenced scientific research may be inferred from the fact that this illustrious physician belonged to the sect of the Dogmatics. Although he professed to believe that the axioms from which he reasoned were founded on facts, he yet disregarded individual facts and the detail of experience as of little value in comparison with his preconceived theories of the nature of diseases. On the whole, he adhered to the mingled dogmatism and scepticism of Hippocrates. His two fundamental maxims were: (1) that disease is something contrary to nature, and must be overcome by that which is contrary to the disease itself; and (2) that nature is to be preserved by that which has relation with nature. In his treatment, he made little of the symptoms of diseases, arguing that these would disappear with the disease as soon as the latter was conquered.

In the West, medical science, after the days of Galen, underwent a sudden and complete eclipse. In the Byzantine empire, the medical schools, after the opposition made by Christians to anatomy, consisted chiefly of copyists and commentators on Hippocrates and Galen. But the names of Oribasius, Aetius, and Procopius, are obscured by the greater fame of Paulus Ægineta, in the earlier half of the seventh century.

The independent research, which had been abandoned or stigmatised in Christian countries, was taken up by the Saracenic schools. Under Ebn Sina (Avicenna) and Avenzoar they reached their highest glory in the East and West respectively. But the victories of the Turks in the former, and in the latter the downfall of Moorish dominion in Spain, at once and finally arrested its progress.

In mediæval Europe, the genuine cultivation of medical science soon provoked the opposition of the hierarchy; and the imprisonment of Roger Bacon, with the posthumous conviction of Peter of Apono, answered to the penalties inflicted on Galileo. But when, in the person of Leo X., the powers of the papacy were wielded by one whose attachment to the traditional belief has not been considered very strong, medical science again revived, and the Greek culture then introduced insured the overthrow of the old coercive system.

This so-called revival of learning had an immediate effect on England. In 1484, Thomas Linacre, founder of the College of Physicians of London, attended at Florence the lectures of the Athenian Chalcondylas. A century later, Foes had translated the Hippocratic writings, and Fernel had questioned the dogmas of Galen.

Into the later history of the science we are precluded by our limits from entering. Some account of the most distinguished physicians and of their several discoveries may be found in the article ANATOMY. For the details of medical and surgical science, the reader is referred to the accounts given of the several diseases, and to the articles CHEMISTRY; DIGESTION; FOOD; MORPHOLOGY; NUTRITION; TELEOLOGY.

A compendious account of ancient surgery is given in the article 'Chirurgia' in Dr. Smith's *Dictionary of Greek and Roman Antiquities*. (See also the articles on Celsus, Galen, Hippocrates, in Smith's *Dictionary of Greek and Roman Biography*; *Encyclopædia Britannica*, art. 'Medicine;' Henri Martin, *La Foudre, l'Electricité, et le Magnétisme chez les Anciens*.)

Surinamine. A crystallisable alkaloid obtained from the bark of the *Geoffroya Surinamensis* (now called *Andira inermis*) or *Surinam bark*.

Surmark. In Shipbuilding, an abutment temporarily placed on the outside of a rib, or timber, to give a hold to the riband by which, through the shores, it is supported on the slipway:

Surmounted. In Architecture, a term sometimes used to denote an arch or dome which rises higher than a semicircle.

SURMOUNTED. In Heraldry, a bearing is said to be surmounted by another bearing which extends not only across it, but across the field also; therein differing from *charged*, e.g. a pile *surmounted* by a chevron; which in this case extends across the field.

Surname (Fr. surnom; Span. sobrenombre, from Lat. super, *over*, and nomen, *a name*). In modern European usage, the family name of an individual; but often used for any distinguishing name. [NAME.] According to Ducange, the use of surnames in France began about the year 987, when the barons adopted the practice of designating themselves by the names of their estates. This has been the general, though by no means the uniform origin, of family names in the nobility of Europe; some having been derived from badges, cognisances, the nicknames applied to individuals, &c. Among the commonalty of this country, surnames are said not to have been general before the reign of Edward II. It will be found on examination that a great number of them originate in the still older custom of adding to the son's Christian name that of the father by way of distinction; many more from the names of trades; and many more from accidental distinctions, as of size or colour, probably applied in the first instance to the founder of the family.

Surplice (Low Lat. superpellicium, apparently from pellis, *skin*). This ecclesiastical vestment is thought by Mr. Palmer (*Orig. Liturg.* ii. 320) to have been at one time not different from the alb. It now has wider sleeves, a difference which is thought to have originated in some distinction between the dress of a superior and inferior order of clergy. It dates from the twelfth century. The vehement objections entertained by the Puritans of the sixteenth century to its use are well known. [VESTMENTS.]

Surrebutter. [PLEADING.]

Surrejoinder. [PLEADING.]

Surrender (perhaps a corruption of Fr. se rendre, *to yield oneself*). In Law. 1. A deed by which the tenant of a particular estate or interest conveys his interest to the remainder-man or reversioner, immediately expectant on the determination of that estate, as, for instance, when a tenant for years gives up his lease to the freeholder. 2. A surrender of copyhold or customary estates is the yielding up of such estates by the tenant into the hands of the lord for purposes expressed in the surrender. This is the common method of conveying copyhold lands, the lord being in general bound to admit the party in whose favour the surrender is made. [COPYHOLD.]

Surrogate (Lat. subrogatus). In Law, one substituted for or appointed in the room of another. The term is commonly used in the ecclesiastical courts as the description of an officer who acts as deputy for the bishop's chancellor.

Surtout. In Heraldry, a figure borne over another, and obscuring part of it.

Surturbrand. A kind of fibrous Brown Coal or Bituminous Wood found in Iceland. It resembles Bovey Coal.

Surveying (Fr. survoir, *to overlook*). In Practical Mathematics, the art of determining the boundaries and superficial extent of a portion of the earth's surface. The object of a survey may be either to ascertain the contents of a field or portion of land, or to determine the relative distances and bearings of the most prominent objects of a country for the purpose of constructing a map, or to determine the form and dimensions of a portion of the earth's surface with a view to deduce the magnitude and figure of the earth by comparing the geodetical distances between given points with their astronomical positions. In all cases the operation is conducted on the same principles; but while the first requires only the application of the merest elements of arithmetic and trigonometry, the last can be accomplished only with the aid of instruments of the most refined description, and processes of calculation deduced from mathematics of the highest order.

In measuring land, all the lines and the surfaces whose contents are to be found are reduced to the same horizontal plane, on the principle that as plants shoot up vertically, no greater number can be produced on the slant side of a hill than would grow on the area covered by its horizontal base. When the lines actually measured are not horizontal, they are therefore multiplied by the cosines of their respective inclinations to the horizon.

For the linear measurements, a chain is employed consisting of 100 links, its whole length, 22 yards, being such that one *square chain* is equal to the tenth part of an acre. In order to avoid decimal fractions, surveyors usually set down all the measures in links; and when the contents of a field are cast up in square links, it is only necessary to mark off the five last figures as decimals in order to have the contents in acres, the number of square links in an acre being $100 \times 100 \times 10 = 100,000$.

As the measurement of angles is in general an operation much less liable to error than the measurement of linear distances, the skilful surveyor, in cases where the surface to be measured is of considerable extent, will avoid making further use of the chain than is necessary for obtaining the data requisite for a trigonometrical computation. The most convenient instrument, and that which is almost universally employed in land surveying for the measurement of angles, is the THEODOLITE, which, from the nature of its construction, gives the angles reduced to the plane of the horizon, and consequently renders a computation for that purpose unnecessary. As auxiliaries to the theodolite, and for the purposes of sketching and filling in the details of a map, the PLANE TABLE and the PRISMATIC COMPASS are used; and in order to determine the bearings of the several objects observed from any

station with reference to the cardinal points of the horizon, a compass and needle accompany the theodolite.

It frequently happens in surveying, that triangles are to be measured whose sides contain very acute or obtuse angles. As in such cases a small error in the angular measurement would lead to very erroneous results, the practice usually adopted for finding the area is to measure the longest side of the triangle and the perpendicular let fall upon it from the opposite angle, the area being half the product of the side into the perpendicular. For the purpose of tracing the perpendicular, the simple cross-staff may be employed; but the instrument called the *optical square* (which is merely a small shallow circular box containing the two principal glasses of the sextant fixed at an angle of 45°) will effect the purpose with greater accuracy. The method of using it is obvious. If the observer moves forward or backward in the straight line A B until the object B seen by direct vision coincides with another object C seen by reflexion, then a straight line drawn to C from the point at which he stands when the coincidence takes place will be perpendicular to A B. The box sextant might evidently be employed for the same purpose.

Since every plane figure may be regarded as composed of a certain number of triangles, the whole theory of land surveying resolves itself into the measurement of the areas of plane triangles. For computing the area of a triangle it is necessary to know the length of at least one side; and when this is known, together with any two of its other parts, the remaining parts and the area are computed by the rules of trigonometry.

In surveying an estate, the usual practice is to measure round it with a chain, and observe the several angles with the theodolite; and if the boundaries are very irregular, a straight line is to run between two points so as to cut off one or more of the bendings, and the perpendiculars or *offsets* from the straight line to each bending are measured with a rod or offset staff, the most convenient length of which is ten links. By this means the spaces included between the actual boundaries and the assumed straight lines are computed; and the sides and angles of the interior polygon being known, its area may be formed without resolving it into triangles. [POLYGON.]

Trigonometrical Survey.—When a survey is to be effected on a large scale, as for making a geometrical map of a country, or for measuring an arc of the terrestrial meridian, not only is minute accuracy required in all the practical parts of the operation, but it becomes necessary to have regard to the curvature of the earth's surface, the effects of temperature, refraction, altitude above the sea, and a host of circumstances of which the influence is wholly unappreciable in the practice of ordinary surveying. Geodetical measurements of this kind have been executed in various countries. [DEGREE.] The first undertaken in our own country was that of General Roy, begun in 1783, for the purpose of connecting the Greenwich Observatory with the French triangulation which had been carried on from Paris to the coast opposite Dover, and consequently for determining the difference of the meridians of the two observatories by actual measurement. This gave rise to a more important operation; namely, a general survey of the kingdom, begun in 1791 under the direction of the Board of Ordnance. A brief description of the methods employed in conducting the different parts of this splendid national undertaking will probably be the best means we could adopt to explain the nature and objects of an accurate trigonometrical survey.

Measurement of Base.—This is the fundamental, and probably the most difficult part of the whole operation, and must be executed with the most minute accuracy, as any error committed in its determination will affect all the distances deduced from it, and be multiplied in the ratio of these distances to the length of the base. First of all, a suitable piece of ground, on which a straight line of not less than five or six miles can be laid down, must be selected and carefully levelled; and a measuring apparatus employed, of which the length is exactly known in units of a standard scale. General Roy's base on Hounslow Heath was first measured with deal rods; but as these were found to be affected by the hygrometrical changes of the atmosphere, it was again measured with glass tubes twenty feet in length, furnished with a peculiar apparatus for making the contacts. In the subsequent measurement of the same line for the Ordnance Survey, two steel chains of 100 feet in length, made by Ramsden, were employed. One of these was used as a measuring chain; the other was kept for the purpose of comparing the measuring chain with it before and after the operation. In the act of measuring, the chain was laid in a trough supported on trestles, and was stretched with a weight of fifty-six pounds. The same apparatus was employed in measuring five other bases in different parts of the country, for the purpose of verifying the accuracy of the work. For the measurement of the Lough Foyle base in the survey of Ireland, Colonel Colby employed a compensating apparatus formed of bars of different metals, so arranged that the distance between two points viewed by compensation microscopes remains constant under all changes of temperature. The length of the Hounslow Heath base was nearly 5·2 miles; that of the Irish base about 8 miles. (*Account of the Measurement of the Lough Foyle Base*, 1847.)

Selection of Stations.—The next step in the operation is to divide the country to be surveyed into a series of connected triangles. The choice of the stations which form the angular points must depend in some measure on the nature of the country; but where circumstances admit of a selection being made, it is very important to form the triangles so that

the small unavoidable errors of observation shall produce the least errors possible in the resulting sides. The conditions required for this purpose are most nearly fulfilled by making the triangles as nearly as possible equilateral. (Galloway 'On the Determination of the most probable Errors of Observation in a portion of the Ordnance Survey,' *Mem. Royal Ast. Soc.* vol. xv.)

Signals.—Various plans have been adopted in the course of the survey for marking and rendering visible the stations at which the instrument is successively set up. At first flag-staffs were chiefly used, carrying lamps and concave reflectors for night observations. Such signals could be seen in the telescope of the great theodolite at distances of 20 or even 24 miles. Bengal lights, fixed in small sockets, were used for more distant stations. In the mountainous countries of Scotland and Ireland, and where the sides of the triangles generally exceeded 50 and sometimes even 100 miles in length, conical piles of stone were erected on the summits of hills; and although the signals were attended with this disadvantage, that they could only be seen when the atmosphere was clear (and the surveying parties were frequently compelled to remain for weeks on the mountains before a single observation could be made), yet from the steadiness of the object observed they were found on the whole to be preferable to any night signals previously tried. When the theodolite was to be set up at a station which had been already observed from another, the pile was thrown down, and the instrument placed exactly over its centre. The heliotrope, and small plane mirrors, have likewise been occasionally employed with success. (On this subject, see Mr. Drummond's paper in the *Phil. Trans.* for 1826.)

Reduction to Centre of Station.—In observing the angles at any station, it is supposed that the centre of the instrument is placed exactly at the centre of the station. This condition was rigidly adhered to in the Ordnance Survey of Britain by erecting signals on purpose; but where the saving of expense is an object, it is often convenient to take advantage of spires, towers, &c., in which case the instrument cannot always be placed in the required position. In such circumstances, the observation is made at a point near the station, and the angle at that point subtended by two remote objects is reduced to that which would have been observed if the instrument had been placed exactly at the centre of the station.

Reduction to the Horizon.—Another indispensable condition is, that the angles observed at each station be reduced to the plane of the horizon. When the theodolite is employed for measuring the angles, this reduction is effected by the instrument itself; but when the angles are measured with a repeating circle or sextant, a reduction is necessary, unless the two distant objects observed be in the same horizontal plane with the instrument, which will rarely happen.

Spherical Excess.—The sum of the three angles of any spherical triangle exceeds 180° by a quantity which is called the ***spherical excess***, and which we shall denote by E. If the observations could be made with absolute accuracy, the sum of the three observed angles of any triangle on the ground would be 180° + E; the difference of their sum from this quantity is the aggregate error of the three observed angles, and must be distributed among those angles so as to render the sum precisely 180° + E before the sides are computed. It is therefore necessary to determine E. Let S denote the area of the triangle in square feet, r the number of feet in the radius of the earth, and $\pi = 3{\cdot}14159$; then E is given in seconds by this formula [SPHERICAL EXCESS]:

$$E = \frac{S + 648000''}{\pi r^2}$$

(648000 being the number of seconds in 180°). In order, therefore, to compute E, we must previously know the values of S and r. Now with respect to S, it is to be observed that in every case which can arise in practice the area of the triangle must be a very small quantity relative to r^2, so that in order to find E it is not necessary to compute S with great precision. A sufficiently near value will be obtained by calculating one of the unknown sides as if the triangle were a plane one, and computing the area from the formula $S = \frac{1}{2}\,a\,b$ sin C. (*Measurement of Lough Foyle Base*, p. 126.)

With respect to r, which is here taken to represent the radius of curvature of the surface of the triangle in question, it is to be remarked, that by reason of the ellipticity of the earth, the radius of curvature of any arc on the earth's surface varies not only with the latitude of the place of observation, but also with the direction of the arc in respect of the meridian. For the present purpose it would be sufficiently accurate to assume r as the radius of the meridian; but as the radius of the perpendicular and oblique arcs is required in other parts of the computation, we shall here give the formulæ from which they are computed. Let R be the radius of curvature of the meridian at latitude l, R′ the radius of the circle perpendicular to the meridian, and r the radius of a great circle making an angle θ with the meridian; also let p denote half the polar axis of the earth, or 20,853,810 feet (Airy's value), and e the ellipticity, or the difference between the equatorial and polar axes divided by the polar axis ($= 1 + 301{\cdot}026 = {\cdot}003322$); then

$$R = p\,(1 - e + 3\ e \sin^2 l)$$
$$R' = p\,(1 + e + e\ \sin^2 l)$$
$$r = R\,\left(1 + \frac{R' - R}{R'} \sin^2 \theta\right)$$

Since the inclination θ is different for each of the sides of the triangle, a mean value of r may be found by making $\theta = 45°$, in which case $\sin^2\theta = \frac{1}{2}$: and as the curvature varies very little through a considerable extent of country, the same value

of r may be used for all the triangles within a zone of two or three degrees of latitude. Suppose, then, the value to be computed for the mean latitude of a chain of triangles, the formula for the spherical excess will be

$$E = \frac{a\, b \sin C \times 648000}{2 \pi r^2}$$

It is proper to remark that in general E is a very small quantity. When the sides of the triangles are about 20 or 30 miles, it will seldom exceed 4 or 5 seconds of a degree; but in some of the great triangles connecting Ireland with the west coast of Scotland its value was found to exceed 30 seconds.

Having computed the spherical excess E, make $e = A + B + C - (180° + E)$—A, B, C being the observed horizontal angles; then e is the error of the sum of the observed angles; and if there be any reason for supposing that any one of the angles has been less accurately determined than the others, the error must be equally divided among them, or a third of e must be added to or subtracted from each angle, as the error is in excess or defect, and the results will give the angles from which the sides are to be computed.

Calculation of the Sides.—The angles being thus corrected for errors of observation, it now remains to compute the two unknown sides of the triangles. The computation may be made by the ordinary rules of spherical trigonometry; but a better method, practised by Delambre, and adopted in the Ordnance Surveys of Great Britain and Ireland, consists in first computing from the observed horizontal angles the corresponding angles formed by the chords of the terrestrial arcs, and then calculating the triangle as a plane one. In this manner the chords of the spherical arcs are found, whence the arcs themselves are easily obtained.

Legendre's Theorem.—Another method of computing the sides, which has been generally adopted in surveys on the Continent, is derived from a theorem which was discovered by Legendre, and is demonstrated in his *Elémens de Géométrie*. 'If from each of the angles of any small triangle on the surface of a sphere or spheroid one-third of the spherical excess be deducted, the sines of the angles thus diminished will be proportional to the lengths of the opposite sides, and consequently the sides may be computed as if the triangle were rectilineal.' This is the easiest method of any; and, in fact, if the three angles are assumed to have been equally well determined, the previous computation of the spherical excess is not necessary for the calculation of the sides, though it will be required for estimating the relative accuracy of the observations.

Latitudes, Longitudes, and Azimuths.—When the sides of all the triangles have been computed, the distances between the stations become known; but in order to complete the survey, it is still necessary to determine the astronomical positions of the principal stations, together with the bearings of the sides of the triangles with respect to the terrestrial meridians. For this purpose the latitude and longitude of one of the stations, and the azimuth of another as seen from it, must be found by astronomical methods [AZIMUTH; LATITUDE; LONGITUDE]; but when this has been done these elements may be computed for each of the other stations in the chain of triangles, provided the dimensions and ellipticity of the spheriod are assumed to be known.

Calculation of Altitudes.—The only element which remains to be determined, in order to complete the survey, is the relative altitudes of the different stations or principal points. At every station the elevation or depression of each of the others observed from it is measured with the theodolite; but owing to the curvature of the earth and the refraction of light, a calculation is necessary in order to determine their true differences of level or of distance from the centre of the earth.

In surveying a line of railway or canal, the first thing to be done is to traverse the country intervening between the proposed termini, so as to judge by a reconnaissance, or eye survey, what is the most elegible route. A more detailed examination is subsequently made, when the levels are taken, so as to balance the earthworks as nearly as possible, and the line is then staked out. [RAILROADS.] In marine surveying, the main points are fixed by astronomical observation.

(*Trigonometrical Survey of England and Wales*; Delambre, *Base du Système Métrique*; Puissant, *Traité de Géodesie*; Id. *Nouvelle Description Géométrique de la France*; *Ency. Brit.* art. 'Trigonometrical Survey.')

Surveying, Naval. The science of determining the lines on which seas may be safely navigated. The duty consists in ascertaining the depth of water by sounding, in carefully delineating on charts the points at which the depth changes, and by observing the bearings of natural or artificial objects, which may enable navigators to determine their exact position and course.

Survivorship. In the doctrine of Life Annuities, a reversionary benefit contingent upon the circumstance of some life or lives *surviving* some other life or lives, or of the lives falling according to some assigned order. For the solution of the different questions which can be put relative to the values of annuities and assurances in every order of survivorship, where there are only three lives, see the treatises of Baily and Milne; or the 'Essay on Probabilities' in the *Cabinet Cyclopædia*. [ASSURANCE; EXPECTATION OF LIFE.]

Sus (Lat.; Gr. ὗς). The generic name given by Linnæus to those hoofed mammals which have on each foot a pair of large digits with a small one on each side, shorter, and more backwardly placed. Lower incisors procumbent, opposed to upper ones. Canines exposed, and in the males usually recurved, upward. The muzzle terminated by a truncated snout fitted for turning up the ground. Non-ruminant. This

generic name is retained for the species of wild boar and their domesticated descendants of Europe and Asia. But certain African kinds have been separated under the names *Potamochœrus* and *Phacochœrus*, and the South American kinds under the name *Dicotyles*: the whole now forming the family of non-ruminant Artiodactyles, called *Suidæ*.

Susannite. A mineral with the same composition as Leadhillite, which it also closely resembles in appearance, found in crystals on the Susanna lode at Leadhills in Lanarkshire.

Suspension. In Ecclesiastical Law, suspension from the right of exercising an office, and from receiving the emolument thereof (ab officio et beneficio), is a punishment inflicted on the clergy by sentence of the ecclesiastical court. Laymen may also be suspended ab ingressu ecclesiæ for brawling in a church, or the like, and condemned to pay the costs of the proceedings.

Suspension Bridge. In Architecture, a bridge in which the roadway, instead of being carried over the supporting points, is suspended from them, the supporting points being chains or other flexible materials. The principle has recently been carried to a great extent in this country, as in the case of the Menai bridge; but its application is old, and has long been practised among people who have attained very little if any skill in the arts. [BRIDGE.]

Sussex Marble. A variety of limestone which constitutes one of the fresh-water deposits of the Wealden group; it abounds in shells of *Paludinæ*, a genus of fresh-water Univalves. It occurs in layers varying from a few inches to upwards of a foot in thickness, the layers being separated by seams of clay or of friable limestone.

Suttee. This word, more correctly written sati or satee, is akin to the Sanscrit SACTI, the term applied to the female power in nature. This power could be approached only after purification, and various rites of this nature were in process of time denoted by this word, which was especially used by the Brahmins to signify the self-immolation of widows on the funeral pile of their husbands. The justification for this practice, and the obligatory precept on which it rested, was found by them in a passage of the Rig Veda, which, as translated by Colebrooke, runs thus: 'Om! let these women, not to be widowed, good wives adorned with collyrium, holding clarified butter, consign themselves to the fire. Immortal, not childless, not husbandless, well adorned with gems, let them pass into the fire whose original element is water.' This passage, Professor Max Müller asserts (*Comparative Mythology*, 23), has been corrupted and falsified by the Brahmans to support their cruel tenet. The real meaning of the verse, in his judgment, is the following: 'May these women who are not widows, but have good husbands, draw near with oil and butter. Those who are mothers may go up first to the altar, without tears, without sorrow, but decked with fine jewels.' The verse is thus addressed, not to the widows, but to the other women, who have to pour oil and butter on the pile; while in a subsequent verse the widow is ordered to leave her husband and return to the world of living men. 'Rise up, woman, come to the world of life; thou sleepest nigh unto him whose life is gone. Come to us. Thou hast thus fulfilled thy duties of a wife to the husband who once took thy hand and made thee mother.'

The injunction to self-immolation, thus obtained by changing the words *yonim agre* into *yonim agneh* (the womb of fire), Prof. Max Müller stigmatises as 'perhaps the most flagrant instance of what can be done by an unscrupulous priesthood. Here have thousands and thousands of lives been sacrificed, and a fanatical rebellion been threatened, on the authority of a passage which was mangled, mistranslated, and misapplied.' He urges, further, that the existence of the word *vidhavâ* (widow) suffices of itself to prove that this practice of self-immolation is comparatively modern. 'If this custom had existed, the want of having a name for widow would hardly have been felt, or if it had been, the word would most likely have had some reference to this awful rite.' But in Sanscrit *dhava* is *a man*, and from this word by the prefix of the preposition *vi*, without, is formed *vidhavâ*, husbandless; and 'if the custom of widow-burning had existed at that early period, there would have been no vidhavâs, no husbandless women, because they would all have followed their husbands into death.'

If, however, this evidence proves beyond all question that the idea of self-immolation, as incumbent on all widows, was at first unknown, it can scarcely prove the negative, that there were no widows who sacrificed themselves. It is conclusive against the universality or frequency of the custom, but not against the theory of self-immolation. It may further be urged that Professor Max Müller's argument fails altogether to account for the origin of the practice, except by attributing it to the disinterested cruelty of a sanguinary priesthood. But even if we grant a position from which we may have a natural shrinking, it may fairly be doubted whether the corruption of *agre* into *agneh* would have sufficed to introduce the practice, however powerful might be the priesthood which enjoined it. Such a fraud might convert into a precept of general obligation a practice which had been the privilege or the pride of a few, but it could scarcely have insured the acceptance of a duty, which could on this hypothesis have had for them no meaning and must have appeared the mere arbitrary command of a sacerdotal caste. Hence we must go further, if we wish to account for the origin of the custom; and it has been thought that the later Brahmanic teaching is connected with mythical phrases and legends familiar to some, at least, among the Aryan nations. If the custom was not general, and if at the same time it existed before the corruption of the Vedic text, it would follow that self-immolation was practised on

the death only of kings, chieftains, or great warriors; and if the death of such men was compared, as we know that at certain stages of thought it commonly is, to the putting out of the light of day, to the sinking of the sun into the dark sea, then the analogy of the earthly wife to the bride of the sun might, it is urged, very naturally suggest itself. The forms which this idea assumed in Hellenic and Teutonic mythology have been noticed in the articles MYTHOLOGY, PARIS, and SIGURDR; and it can scarcely be questioned that Œnônê and Brenhyldr are genuine instances of suttee, whether the practice took its rise from mythical phrases and ideas or whether it did not. But, apart from such striking examples, the tone and spirit of innumerable legends pointed to the conclusion that life could have no attraction for the wife of the hero, whose career and death had resembled that of the glorious sun-god. Such a conclusion might long remain a mere idea, while here and there it might be carried out by some whose very heart was broken by their grief; and if during an indefinite period this self-devotion was occasionally permitted in the wives of kings and heroes, there is nothing surprising in the fact that a powerful priesthood succeeded in the sequel in representing the rite of immolation as a duty incumbent on all women who desired to win a pure and unspotted name.

But, whatever may be its origin, it is certain that the custom had under Brahmanic influence become frightfully common. The English government in the territories under its sway interfered at first only to insure, as far as possible, that the sacrifice should be strictly voluntary on the part of the widow. The presence of a government officer for this purpose imparted to the custom an air of legality which was far from promoting the object of such interference. At length, in December 1829, the rite was abolished in the British dominions by Lord William Bentinck. (Forbes, *Oriental Memoirs* ii. 26; Heber, *Journal* i. 70; Crawford, *Indian Archipelago* vi. 2.)

Sutural (Lat. sutura, *a seam*). In Botany, this term is applied to parts which bear some definite relation to a suture or line of junction between the different parts. Thus, the term *sutural dehiscence* means that a seed-vessel splits along the line of junction of two valves.

Suture (Lat. sutura, *a seam*). In Anatomy, the junction of bones by their serrated or toothed margins: the bones of the skull are so united.

SUTURE. In Entomology, the line at which the elytra meet, and are sometimes confluent.

SUTURE. In Mammalogy, the line formed by the incumbent ends of converging series of hairs of the integument.

Svanbergite. A pale-red mineral found at Wermland in Sweden; and chiefly composed of sulphuric acid, phosphoric acid, alumina, lime, soda, and water. The name Svanbergite has also been applied to Platiniridium.

Swab (A.-Sax. swebban, *to sweep*). A bundle of yarns tied together to form a sort of mop used in drying the decks of a ship.

Swallow (A.-Sax. swalewe, Ger. schwalbe). A name equivalent to the subgeneric term *Hirundo*, appropriated in Modern Ornithology to the British species called *bank*, *chimney*, and *window swallow*, and to foreign allied forms dismembered from the swifts.

Swamp (A.-Sax. swam, Dan. svamp). Ground habitually so moist and soft as not to admit of being trod on by cattle, but, at the same time, producing particular kinds of trees, bushes, and plants. A swamp differs from a bog and a marsh in producing trees and shrubs, while the latter produces only herbage plants and mosses.

Swamp-ore or **Swampy Iron-ore.** An old name for BOG IRON-ORE.

Swan (Ger. schwan, Dan. svane). Of the noble web-footed birds so called there are three British species—the Hooper, or Bewick's, the wild, and the tame swan. These form the type of the subgenus *Cygnus*. The wild swan and Hooper ought perhaps to be regarded as the only true native species. The tame swan (*Cygnus olor*) is superior in bulk to either of the wild species, and is at once distinguished by a large black callous knob on the base of the bill. Both the wild species are peculiarly characterised by convolutions of the windpipe, extending in the mature bird through the whole length of the keel of the sternum. These convolutions are horizontal in the *Cygnus Bewickii*, and vertical in the *Cygnus ferus*.

Swanhild. In Teutonic Mythology. [SIGURDR.]

Sward. Green turf; i.e. the surface of land under pasture grasses. A fine sward may be called the characteristic feature of British landscape, not being found in the same degree of perfection in any other country, not even in Ireland.

Swash Letters. In Printing, letters which had their terminations projecting considerably beyond the shank thus: K Q R &c. They have been revived of late years with the re-introduced old-fashioned types.

Sweating Sickness. An epidemic of great severity which appeared in England at different periods towards the end of the fifteenth and beginning of the sixteenth century. It is generally believed to have broken out in the army of the duke of Richmond, afterwards Henry VII., on his landing at Milford Haven. It spread over various neighbouring countries, and was called *sudor Anglicus*. Curiously enough, it mostly attacked persons of rank, and those in good health. The disease may be described as a fever commencing with heat in some one limb or in some part of the body, spreading over the whole surface, and followed by profuse and exhausting sweating, with insatiable thirst. Restlessness, nausea, delirium, and headache, with irregular action of the heart, were always present. Patients often died in from two to four hours after the sweat set in.

The last visitation of the scourge in England was in 1551. [PLAGUE.]

Swede. A kind of Turnip with yellow flesh, introduced from Sweden, much cultivated as a root crop by agriculturists. Its botanical name is *Brassica campestris rutabaga.*

Swedenborgians. Those persons who on religious subjects receive the testimony of Swedenborg, a Swedish nobleman who died in 1772. In his work entitled *Arcana Cœlestia*, and in his *Apocalypsis Revelata*, Swedenborg professes to make known what he calls the Science of Correspondences, or that analogy between spiritual and natural things, according to which, he says, the Word of God is written. Thus, Jerusalem signifies not only the chief city of Palestine, but the Lord's church, and more specifically the religious doctrines by which persons are united into a church. Hence the new Jerusalem, seen by John descending from God out of heaven, signifies a new church, or a new developement of pure doctrines from the Holy Word, which will eventually regenerate the world. In these doctrines may be considered as most prominent the acknowledgment of the Lord Jesus Christ as the one God in whom is centred the Divine Trinity, and the necessity for uniting charity with faith, or, in other words, for the keeping of the divine commandments, in which is included the performance of every duty. The admirers of Swedenborg, who form a separate religious body, which they denominate the New Church, have places of worship in London and other towns of England, and are greatly increasing in America. In the religious census of 1851 the number of their congregations in England is stated at fifty.

Sweeps. Very long oars used occasionally in the bows of ships to assist the action of the rudder during a calm.

Sweet Bay. Another name for the Noble Bay, *Laurus nobilis.* [LAURUS.] In America, the name is applied to *Magnolia glauca.*

Sweet Flag. The *Acorus Calamus*, an aromatic native plant found in moist situations in this country. [ACORUS.]

Sweet Sop. The fruits of *Anona squamosa* and *A. sericea.*

Sweetbread. The thymus gland of the calf is employed as food, under this name; it contains about seventy parts of water, and thirty of nutritious matter, chiefly of an albuminous character. 'A fresh sweetbread when plainly cooked (by boiling) and moderately seasoned, forms a very agreeable and suitable dish for the convalescent; but, when highly dressed, is improper both for dyspeptics and invalids. (Pereira *On Diet.*)

Swell (a Teutonic word). In Music, a part of an organ. It consists of a small separate organ enclosed in a box, the whole being contained within the case of the large instrument. The box has shutters or louvre boards which can be opened or shut by means of a pedal, so as to allow the sound of the pipes within either to be heard distinctly or partly suppressed at the pleasure of the player, and thus to produce a swelling effect, whence the name.

Swell of the Muzzle. [GUN.]

Swietenia (after Baron von Swieten, a Dutch botanist). *Swietenia Mahagoni*, the tree which yields the Mahogany of commerce, is the sole representative of this genus of *Cedrelaceæ*, and is peculiar to the warmer parts of America and the West Indies. It forms a stately tree of some sixty or eighty feet high. The first discovery of the beauty of mahogany wood is attributed to the carpenter on board Sir Walter Raleigh's ship, while lying off Trinidad in 1595. At Honduras the wood is not considered to be in perfection when under 200 years old. The bark is considered a febrifuge, and the seeds prepared with oil were used by the ancient Aztecs, as they are by the modern Mexicans, as a cosmetic.

Swimmers (a Teutonic word). The web-footed or aquatic birds (*Natatores*, Ill.; *Palmipedes*, Cuv.) are so called; also a tribe of spiders (*Araneidæ natantes*) which live in water, and there spin and spread abroad filaments to entrap their prey.

Swimming. Amongst land-mammals, man seems to be the only one without the natural faculty of swimming. It is acquired by practice, imitation, or being taught. The learner, immersed to the neck, is directed to begin by placing the palms of the hands together and pushing them forward about an inch under water, the knees at the same time being drawn up under the body, as if preparing for a spring. The next movement is that of divarication of the hands, in the form of a scoop, the fingers being kept close and the thumb downward, so as to thrust back the water with a wide sweep of the entire arm from the shoulder. At the same moment the legs are thrown back, the feet pushing away the water beneath, the effort being that of making a spring forward. When the arms have made their utmost horizontal extension, they are to be bent with the elbows drawn back until the ball of the thumb of each hand gently touches the ribs; the palms, being then again brought together, are pushed forward in a direct line (the tips of the two thumbs passing under the chin) to repeat the stroke. In like manner, the motion of the legs and feet having been made, the action is relaxed, and the legs stretched out with the toes inclined downward till the knees are again drawn up to repeat the stroke. The principal propelling power is in the legs, the arms and hands acting chiefly in bearing up the head above the surface. It is essential that the action of arms and legs be simultaneous. Man thus most closely imitates the swimming of the frog.

To one in danger of drowning, it is more important to know how to *float* than how to *swim*. The exercise of the muscles in a good swimmer necessitates more frequent respiration, and exhausts the strength. If a shore be within reach and no help nigh, the swimmer may, indeed, save himself, when the floater

would, at ebb-tide, be carried out. But in the majority of instances, where the life of the immersed depends on human help, the longer the body can be kept afloat the greater the chance of rescue. The specific gravity of the body with the lungs moderately distended with air is less than that of water, especially of sea water. The brain will help to float the skull if it be immersed. The main point is to keep as much of the body under water as may be: only occasional emersion of nose and mouth is essential to breathing. If, on immersion, the chest be well filled with air, and no struggling or act of expiration takes place, the body will rise to the surface, and if the head be then kept well back or down in the water, the nose and mouth will emerge. Then let the floater breathe, expiration by the nostrils being instantly followed by drawing in at the mouth as much air as can be taken. All the part of the head containing the brain should be kept well under water; not a finger or any part of the limbs should be lifted out of water: it would add so much to the sinking weight. A slight extension of the arms under water, with the palms horizontal and gently beating down the water like fins, will help to maintain the prone position of the body.

Swimming Stone. A name sometimes given to the spongy kind of Quartz called FLOAT-STONE.

Swine. [SUS.]

Swine Pox. [CHICKEN POX.]

Swine Stone. [STINK STONE.]

Swing (a Teutonic word). A ship at anchor is said to swing when she changes her position at the turn of the tide.

Switches. [RAILROADS.]

Swivel Gun. In Artillery, a gun fixed on a *swivel*, by means of which it may be directed to any object. Swivel guns are used chiefly at sea.

Sword (a Teutonic word). A weapon of offence used from the earliest historical times, now employed chiefly for cavalry. The knightly sword of the middle ages was broad, straight, two-edged, and acutely pointed with a simple cross piece for its guard. In the sixteenth century, various forms of guards and hilts appeared. The sword for all cavalry in our service, except the household troops, has a blade slightly curved, and 3 ft. 4 in. long, with a handle 5½ in. long. It weighs 2 lbs. 1 oz.

Sword, Order of the. A Swedish military order of knighthood, instituted by Gustavus Vasa.

Sword of State. Four swords are used at the coronation of a British sovereign: 1. The sword of state properly so called. 2. The curtana (curtus, *shortened*), the sword of mercy, which is pointless: it is mentioned by Matthew Paris. 3. The sword of spiritual justice. 4. The sword of temporal justice. These three are carried before the sovereign: he is girt with the first.

Sybarite. A term used metaphorically to designate an effeminate voluptuary; so called from the inhabitants of Sybaris, formerly a town of Italy on the gulf of Tarentum, who were said to have been so enfeebled by sensual indulgence that they became an easy prey to the Crotonians, a people comparatively insignificant in point of numbers, by whom their city was levelled to the ground, B.C. 310.

Sycamore. A hardy ornamental deciduous tree belonging to the Maple family, known by its five-lobed leaves, and its profusion of flat winged twin fruits, popularly called *keys*, and distinguished by the scientific name *Acer Pseudo-Platanus*. This tree is to be distinguished from the Sycomore of the Bible (Luke xix.), which is a species of fig, though probably the name originated in some confusion of ideas as to the identity of both. Indeed, in old books what is now universally called *sycamore* was sometimes written *sycomore*, while the sycomore fig is in some modern versions of the Bible printed *sycamore*. [SYCOMORE.]

Sycee (Chinese sai-sz', *fine silk*). A term, used to denote the fine silver of China, also called *wanyin*, or pure silver. The only currency, in the proper sense of the word, issued by the Chinese government is that of a mixed metal, the coins of which, called *cash*, are strung by means of a square hole passed through the centre of the coin. Ten of these make a *candareen*, ten candareens a *mace*, ten mace a *tael*. Only the cash, however, is coined, with the exception of a depreciated piece, nominally of ten cash, which has a forced circulation within the walls of Pekin. These terms are foreign, the Chinese names being, *li*, *fan*, *tsien*, and *liang*. The cash, by an edict of 1644, was made of seven parts copper and three zinc. But at present a considerable alloy of tin is substituted for the copper, and even lead, iron, and sand are added fraudulently in the provincial mints. The coins are cast.

But the taxes are paid in silver, generally of the purest kind, and known among bankers by the name of *sycee*. This silver is cast into ingots, sometimes small, and weighing little more than 175 grains troy, sometimes so large as to weigh upwards of 5 lbs. troy. The most common weight is rather more than a pound troy. The ingots bear a rough resemblance to a Chinese shoe, and are therefore called *shoes* by foreigners. The fineness of the silver is known by the number of *touches* which it is said to contain; thus *sycee of* 99 *touch* means that the ingot has only one part in a hundred of alloy. The ingots are stamped with the seals of the assayer or banker in evidence of their purity.

The silver currency of the mercantile public, and to some extent of the natives, is derived from foreign dollars. These coins are not, except on rare occasions, and by special proclamation (*Accounts and Papers* 1857-8, vol. xliii.), recognised by the Chinese government. Formerly the Spanish pillar dollar was in great request; at present, the Mexican dollar is current and in the highest favour. The singular circumstance that the Chinese government does not coin silver, and receives its taxes

by weight of fine bullion, is to be explained by the fact that its authority is wholly inadequate to secure the weight and fineness of an internal currency by any mint regulations or police. The public servants are corrupt; and, to judge from some acts of the government, it is not likely that it would preserve the standard which it might at first issue. But the Chinese people, and especially the mercantile classes, are far too astute to be defrauded, and the latter part of the community derive a considerable profit from bullion operations.

It was suggested by Sir John Bowring, that the English government should establish a mint, and coin their own dollars, at Hong-Kong; but the Foreign Office, knowing the great dislike of the Chinese to innovation, did not at first venture on the expense of setting up a mint. Latterly, however, coins, a silver dollar and a half-dollar of nine-tenths fineness, with another coinage in silver of eight-tenths fineness, containing 20, 10, and 5 cent pieces, and also a bronze cent and a bronze mil, have been struck. Some of these coins, though issued at Hong Kong, were struck at Birmingham. These coins, however, are considerably below the standard of sycee.

Sycoma (Gr. σύκωμα, from σῦκον, *a fig*). A fig-shaped excrescence or warty tumour.

Sycomore (Gr. συκόμορος). The sycomore of the Bible is the *Ficus Sycomorus* of the older botanists, but according to more modern views is now sometimes called *Sycomorus antiquorum*. It is a large tree with a thick trunk, out of which, as well as from the larger branches, the fruits issue. These are shaped like the common fig, and have a sweet and delicate taste. The tree is also called Pharaoh's Fig-tree. It is quite distinct from the tree called SYCAMORE.

Syconium (Gr. σῦκον, *a fig*). In Botany, the name applied to such fruits as that of the fig, consisting of a fleshy receptacle loaded with flowers, each producing its own proper seed-vessel.

Syconus. [SYCONIUM.]

Sycophant (Gr. συκοφάντης, from σῦκον, and φαίνω, *I disclose*). It was forbidden by the laws of Athens at one period to export figs. The public informers who gave notice of delinquencies against this fiscal law were extremely unpopular, and hence the word came into use to signify an informer or false accuser generally; in which sense it is constantly used by Aristophanes and the orators. In modern usage it has acquired the sense of a mean flatterer.

Sycosis (Gr. σύκωσις). A tubercular eruption upon the scalp, or bearded part of the face: it sometimes forms a very troublesome impediment to shaving.

Syenite. A granitic aggregate of quartz, felspar, and hornblende, from Syene in Egypt, whence the Romans obtained it for architectural purposes. [GEOLOGY.]

Syepoorite. A sulphide of cobalt, of a steel-colour inclining to yellow, which occurs in grains or veins in primary schist, mechanically mixed with Magnetic Pyrites, at Saipoor, near Rajpootana in North-Western India. It is said to be used by the Indian jewellers to give a rose-colour to gold.

Syllable (Gr. συλλαβή). A syllable, as defined by Girard, is a simple or compound sound, pronounced with all its articulations by a single impulsion of the voice. The principal difficulty in arranging the syllabic construction of language is to ascertain in what cases two or more consonants following each other may be joined in a syllable; which can only be done by an investigation of the mechanism of speech. (Max Müller's *Lectures on Language*, second series, iii.)

Syllabus (Gr. σύλλαβος). A compendium or abridgment, or a table of contents; as a syllabus of lectures, &c.

Syllepsis (Gr. σύλληψις, *a taking together*). A name given by some writers to that idiom of the Greek and Latin languages whereby an adjective predicated of a masculine and feminine substantive is made to accord in gender with the former: e.g. *rex et regina beati*.

Syllogism (Gr. συλλογισμός, *a gathering together*). According to the scholastic system of Logic, adopted by Archbishop Whately, the syllogism is an argument stated in the form of three propositions, having the property that the conclusion follows necessarily from the two premisses, so that, if the premisses be true, the conclusion must be true also. In such arguments the conclusion is contained in the premisses, so that nothing more can be inferred in the third or concluding proposition than is involved in the two which precede it. To this theory of syllogism many objections have been made, some of which are noticed in the article LOGIC; but we think it right to give, without any running comment, a sketch of Dr. Whately's system, reserving for the close of the article a few remarks on some of the difficulties involved in it.

According to this system, as often as the mind observes any two notions to agree with a third, it immediately concludes that they agree with each other: as, A is equal to B; B is equal to C; therefore A is equal to C. Or, if it finds that one of them agrees and the other disagrees with the third, it pronounces that they disagree with each other. In the first of these processes it produces a syllogism with an affirmative conclusion; in the latter, a syllogism with a negative conclusion.

Syllogisms are variously divided: by some into *single*, *complex*, and *conjunctive*, &c.; by others (according to the Oxford system of logic) into *categorical*, *hypothetical*, *conditional*, &c. But the categorical syllogism, consisting of three categorical propositions, is the simplest form, and that to which all other forms can be reduced.

The following are the two canons by which the validity of a categorical syllogism is explained: 1. If two terms, i.e. notions expressed in language [TERM], agree with one and the same third, they agree with each other. 2. If

one term agrees and another disagrees with a third, the first two disagree with one another. Hence are deduced the six following rules:—

1. Every syllogism has three terms only: viz. the middle term, and the two extremes. The subject of the conclusion is called the *minor term*; its predicate, the *major term*: the *middle term* is that with which they are respectively compared. 2. Every syllogism has three propositions only: the *major premiss*, in which the major term is compared with the middle; the *minor premiss*, in which the minor term is compared with the middle; the *conclusion*, in which the major and minor terms are compared together. 3. The middle term must be, in logical language, distributed once at least in the premisses; i.e. it must be the subject of a universal, or the predicate of a negative; otherwise it may happen that one of the extremes is compared with one part of it, and the other with another part. 4. No term must be distributed in the conclusion which is not distributed in one of the premisses; otherwise the whole term would be employed in the conclusion, where part only is employed in the premiss: this error is called an *illicit process* of the major or minor premiss. 5. From negative premisses we can infer nothing; i.e. if two terms disagree with a third, we cannot infer either their mutual agreement or disagreement. 6. If one premiss be negative, the conclusion must be negative; for if one term disagree with the middle, it must of necessity also disagree with the other. The other rules are corollaries deducible from these six.

The *mood* of a syllogism is the designation of its three propositions in their order, according to their respective quantity and quality. By reference to the head PROPOSITION, it will be seen that arbitrary symbols are adopted in logic to mark the quality and quantity of propositions; thus, A stands for a universal affirmative; E represents a universal negative; I a particular affirmative; O a particular negative. These four letters will afford sixty-four different combinations of three letters; but of these the greater part will afford syllogisms erring against some one or more of the rules previously laid down; thus EEE would be at once inadmissible, as exhibiting two negative premisses—against rule 5. By an accurate examination, it is found that eleven moods only will afford correct syllogisms: AAA, AAI, AEE, AEO, AII, AOO, EAE, EAO, EIO, IAI, OAO.

The *figure* of a syllogism consists in the situation of the middle term with reference to the major and minor terms. 1. The first figure is where the middle term is the subject of the major premiss, and predicate of the minor. 2. Where the middle term is the predicate of both premisses. 3. Where it is the subject of both. 4. Where it is the predicate of the major and subject of the minor. Multiplying the moods by the figures, we should have forty-four different syllogisms. But it will be found, on examination, that five moods in each figure (twenty in all) would err against some one or other of the rules before laid down: e.g. AII is an allowable mood in the third figure; but, in the first, it would have an undistributed middle. Of the twenty-four remaining, five are unnecessary; i.e. they are moods in which a particular conclusion only is inferred from premisses which would warrant a universal. The nineteen remaining are expressed in the following mnemonic lines:—

Fig. 1. 4 moods: BA*r*b*A*r*A*, *c*E*l*A*r*E*nt*, *d*A*r*II, *f*E*r* IO*que*, prioris.
Fig. 2. 4 moods: CE*s*A*r*E, *c*A*m*E*str*E*s*, *f*E*st*-I*n*O, *b*A*r*O*k*O, secundæ.
Fig. 3. 6 moods: Tertia *d*A*r*A*pt*I, *d*I*s*A*m*I*s*, *d*A*t*I*s*I, *f*E*l*A*pt*O*n*, BO*k*A*rd*O, *f*E*r*I*s*O*n*, habet: quarta insuper addit.
Fig. 4. 5 moods: B*r*A*m*A*nt*I*p*, *c*A*m*E*n*E*s*, *d*I*m*A*r*I*s*, *f*E*s*A*p*O, *fr*E*s*I*s*O*n*.

One mood in each figure may be given by way of example. The letter M designates the middle term; the letter preceding the proposition, its quantity and quality.

1. A. All excess (M) is sinful.
   A. All gluttony is excess (M): therefore,
   A. All gluttony is sinful. (A syllogism in Barbara.)

2. A. Everything expedient is lawful (M).
   E. Nothing unjust is lawful (M): therefore,
   E. Nothing unjust is expedient. (A syllogism in Camestres.)

3. A. All conquerors (M) are cruel.
   I. Some conquerors (M) are just: therefore,
   I. Some just men are cruel. (A syllogism in Datisi.)

4. A. Whatever is expedient is conformable to nature (M).
   E. Whatever is conformable to nature (M) is not hurtful: therefore,
   E. What is hurtful is not expedient. (A syllogism in Camenes.)

It will be observed that in all these instances the major premiss is presumed to precede the minor; but although this is the most convenient form of reasoning, the minor premiss is, with equal validity, made the first in the series: e.g.

> Brutus is an honourable man:
> Honourable men affirm the truth; therefore,
> Brutus affirms the truth.

This is a syllogism in Barbara, with the minor premiss placed before the major.

The fourth figure is considered to be inverted and unnatural; and the first three figures with their fourteen moods furnish almost every argument which is employed, however far it may be removed in appearance, through the intricacy of language, from the syllogistic form. But all arguments may be brought, by an ingenious process termed *reduction*, into one or other of the four moods of the first figure.

In reducing a syllogism, the premisses may be illatively converted [ILLATIVE CONVERSION] or transposed; since the force of the argument can be altered by neither of these processes.

By this process, we deduce either the same conclusion with the original, or another conclusion from which the original conclusion follows by illative conversion. We have not space to explain, by examples, these various processes. The letters which compose the names of the syllogistic moods are framed to express the manner in which those of the three last figures are reduced into those of the first. The first letter indicates the mood into which those beginning with the same letter are to be reduced: e.g. Bramantip is reducible into Barbara; *m* indicates that the premisses are to be transposed; *s* and *p* that the proposition denoted by the vowel immediately preceding is to be converted—*s* simply, *p* per accidens; *k*, which occurs only in Baroko and Bokardo, indicates that the proposition denoted by the vowel immediately before it must be left out, and the CONTRADICTORY of the conclusion substituted, which is termed the *reductio ad impossibile*.

A hypothetical syllogism is one in which the conclusion is deduced from an hypothetical premiss (called the *major*) and a categorical premiss (called the *minor*). It is of two kinds—conditional and disjunctive; the first subdivided into constructive and destructive.

1. Conditional constructive.	If the demand increases, the supply will increase: But the demand increases; Therefore the supply will increase.
2. Conditional destructive.	If the country is flourishing, agriculture is flourishing: But agriculture is not flourishing; Therefore the country is not flourishing.
3. Disjunctive.	Either A is B, or C is D: But A is not B; Therefore C is D.

It is evident that a disjunctive syllogism may easily be reduced to a conditional. (See the *Compendium of Logic*, by Dean Aldrich, commonly used at Oxford; and the Treatise of Archbishop Whately.)

To the foregoing theory of the syllogism, the chief objection made is that the reasoning process is made to rest wholly on the Aristotelian dictum *de omni et nullo*, an axiom which possesses value and is really intelligible only with a realistic philosophy. It will be readily admitted that nothing is gained or learnt by referring any object to a mere *name* which has been obtained by a comparison of other objects of the same nature. So long as it was supposed that *humanity* was an entity existing apart from all the individual men who have ever lived or may live, the predication, in the case of a given individual, of any quality belonging to this substantia secunda was the assertion of a fact which might be new, and which certainly was important. But when it is maintained that *humanity* is a mere arbitrary name or label under which are grouped certain phenomena which bear a certain resemblance to each other, the dictum of Aristotle is reduced to the identical affirmation that whatever is true of any given number of objects is true of each of those objects, a proposition which cannot be disputed, but which may be dismissed as fruitless and dead. Hence it follows that the syllogism, so long as it is confined strictly within the limits of the scholastic logic, cannot possibly be made a means for the discovery of new truth, and remains at best an instrument for the exercise of mental ingenuity. When we say that all men are mortal, and that Cæsar is mortal because he is a man, we do not really infer the mortality of Cæsar before he is really dead, from the generalisation that all men are mortal. This generalisation was in the first instance obtained only by an observation of individual instances; and when it was found that certain individuals with special points of resemblance or difference resembled each other in undergoing a change called *death*, this result of strict induction was registered in a useful general proposition asserting the mortality of all men or of all animals or of all living organisms.

Thus the province of the scholastic syllogism is reduced to a very narrow compass. It will enable us to test the correctness of our generalisations, but it cannot enable us to arrive at new generalisations; in other words, it cannot add to our stock of the knowledge of phenomena. It is a touchstone for ascertaining the value or the genuineness of treasures already gained, but not an instrument for the discovery of further treasures of which we are in search.

It is further objected that, as all knowledge is gained by induction, and as propositions are concerned not with names but with things or facts, the method which deals with propositions by substituting arbitrary signs as the subject and predicate, and thus makes the validity of the syllogism to depend upon its form is, to say the least, deceptive and dangerous. The system, which makes all reasoning to consist in the observation of phenomena, in the accurate colligation of facts, and the exact ascertainment of their several points of agreement and difference, leaves no room for the notion that the validity of an argument is manifest from the mere form of expression without reference to the meaning of the words employed, i. e. without regard to the things or facts which the words or signs are used to denote. That this notion, although frequently stated without qualification, is really set forth with considerable reserve, is apparent as soon as we proceed to carry it out to its full limits. The assertion, that every argument thrown into the form,

Every A is B; every C is A:
therefore every C is B,

is valid, resolves itself into an absurdity, if for A we substitute *philosophers*, for B *quadrupeds*, and for C *peacocks*. Hence the whole doctrine of moods and figures really requires that in every single case the general proposition shall be in accordance with facts; in other words, that it shall be an accurate induction from the observation of phenomena, while the minor premiss shall state some point of agreement or

difference which has been ascertained by actual search, and is not merely a figment of our imagination. Thus, the form of the syllogism, of itself, proves nothing: and an argument formally correct may be absolutely worthless. Apart from the inductive or experimental examination of phenomena there can, it would follow, be no reasoning and no logic.

The doctrine that no conclusion can be drawn from two particular propositions, is, it is urged, not strictly correct. If the two propositions are severally in accordance with fact, they may form part of an inductive process and carry us over an important stage of our journey, but in any case they must involve some direct conclusion. If we are told that butterflies are not *Hemiptera*, and that bees are not *Hemiptera*, from these two particular propositions (far from drawing no conclusion) we learn that there are two classes of insects which do not belong to the class *Hemiptera*; and at once we see that conclusions drawn from such particular propositions are among the most important in the processes of logic.

Exception has, likewise, been taken to the classification of syllogisms according to the affirmative or negative character of propositions, and to the CONVERSION of syllogisms from one figure to another. Against the former it is urged that all negative propositions may be thrown into an affirmative form by altering the expressions without changing the meaning, and against the latter that the several moods of the second, third, and fouth figures are only modifications of arguments which may be cast into the form of the first. These objections resolve themselves into the assertion that propositions are concerned not with names or notions, but with things or facts: and it is unnecessary to discuss them at length, so long as it is remembered that all generalisations are mere tickets or labels, serving to preserve arrangements of recorded and observed phenomena, and that in the processes of induction fresh knowledge is gained by reasoning not from universals, but from particulars to particulars.

Sylph (Gr. σίλφη, *a kind of insect*). The name given to the spirits of air in the fantastic nomenclature of the ROSICRUCIANS and Cabalists. [CABALA.] The use which Pope has made of this fancy in his *Rape of the Lock* is well known. He seems to have borrowed it from the enigmatical romance called the *Count de Gabalis*.

Sylvanite. A name given originally to native Tellurium, from its being discovered first in Transylvania.

Sylvine. Native chloride of potassium, found with Common Salt at the mines of Hallein in Salzburg, and Berchtesgaden in Bavaria; also sublimed about the fumaroles of Vesuvius. The name Sylvine has reference to the *digestive salt* of Sylvius de la Boë, with which it is identical.

Symbol (Gr. σύμβολον; from σύν, *together*, and βάλλω, *I throw*). A word of many meanings, although now commonly used in one only. 1. The primary meaning of the verb συμβάλλειν expresses the act of several in constituting or throwing together portions to form a whole. Hence σύμβολον signified a treaty or agreement. (Arist. *Polit.*) It seems to be in this sense that the creeds are termed by early ecclesiastical writers *symbols*: either because (as Augustine says) all the fundamental doctrines of Christianity are *collected* in them; or from the old traditionary story, related by Rufinus, that the creed called the Apostles' Creed was formed by each of them contributing a sentence. [CREED.] 2. The mind may be said to put together outward appearances, and collect from them the notion of a thing signified by them; and hence the outward appearances themselves may be called *symbols*, signs, or emblems; while the act of the mind is termed *conjecture* (Lat. conjicio). Thus, the standards of military bodies were called by the Greeks *symbols*; as likewise omens and portents; and expressions or figures denoting a received meaning, as the Pythagorean symbols. In this sense, the early Christians gave the general name of *symbols* to all rites, ceremonies, and outward forms bearing a religious meaning, to the sacraments and the sacramental elements, to the cross, and, in later times, to images and pictures. Symbols, properly so called, must be distinguished from TYPES, and from mere symbolical attributes, such as the figures usually introduced in representations of the four Evangelists. *Symbolical books* are such books as contain the creeds and confessions of different churches: as the three creeds, received by all; the Confession of Augsburg, received by the Lutherans; the articles of the church of England, &c. The Germans call the study of the symbols and mysterious rites of antiquity, and also the study of the history and contents of Christian creeds and confessions of faith, by the name of *symbolics* (mythological or theological). Marheineke's *Institutiones Symbolicæ*, of which the first edition appeared in 1812, is one of their most distinguished works in the latter class.

Symbols. In Mathematics, certain marks by which numbers, quantities, or operations are represented. [NOTATION, MATHEMATICAL.] By a *calculus of symbols* is meant a systematic method of combining symbols according to prescribed laws. [OPERATIONS, CALCULUS OF.] *Symbolic algebra* is that branch of the general calculus of symbols where algebraic symbols and operative rules are considered. (De Morgan's *Double Algebra.*) *Symbolic geometry*, again, is a science wherein the symbols have geometric meanings, and the operations a geometrical character. [QUATERNIONS.] Great progress has recently been made, and especially in England, in the developement of symbolical methods. Recent volumes of the transactions of our learned societies and of our mathematical journals contain valuable papers on the subject by several writers, amongst whom may be mentioned Gregory, Warren, Peacock, Sir W. R. Hamilton, De Morgan, Cayley, Sylvester,

Boole, Hargreaves, Donkin, Carmichael, Spottiswoode, Russell, &c.

Symbols, Botanical. In their descriptions of plants, botanists use certain signs or abbreviations to convey information in the most ready way on certain general facts which have to be recorded, or to express particular attributes in the subject under description. The signs or symbols in most frequent use are the following:—

♂ = male.
♀ = female.
☿ = hermaphrodite, or bisexual.
♂-☿-♀ = polygamous.
♂ ♀ = diœcious.
- ♀ = monœcious.
♂-☿-♀ = triœcious.
① or ○ = annual.
② or ♂ = biennial.
♃ = perennial.
♄ = a tree or shrub.
∞ = an indefinite and considerable number of anything.

! placed after a person's name indicates that an authentic specimen from that person has been seen.

* at the end of a citation denotes that a plant is fully described in the place referred to.

v.v. = seen alive.
v.s. = seen in a dried state.
v.c. = seen cultivated.
v.sp. = seen wild.

′ ″ ‴ When these signs are placed after a number, they express a foot, an inch, or a line respectively; thus, 5′ = 5 feet; 5″ = 5 inches; 5‴ = 5 lines.

A very full account of all such signs is given in the fourth edition of Lindley's *Introduction to Botany*, ii. 384.

Symbols, Chemical. A chemical symbol is the representation of one atom or combining proportion of each elementary substance by the capital initial letter of its Latin name, it being necessary where the names of two or more elements begin with the same letter to add a second, in a smaller character, for the purpose of distinguishing between them. Thus C, Cl, Ca, Cd, Co, Cu, Ce, Cr, are the symbols of Carbon, Chlorine, Calcium, Cadmium, Cobalt, Copper (Cuprum), Cerium, and Chromium; H and Hg are the symbols of Hydrogen and of Mercury (Hydrargyrum); O and Os of Oxygen and of Osmium; and so on. The following table enumerates, in alphabetical order, the simple or elementary substances, with their annexed symbols and atomic weights; i.e. the respective *weights* of each of the elementary bodies which each symbol represents upon the *hydrogen* scale, or in reference to hydrogen as unity:—

	Atomic weight. Old notation.	Atomic weight. New notation.	Symbol.
Aluminum	13·8	27·5	Al.
Antimony (Stibium)	122	122	Sb.
Arsenic	75	75	As.
Barium	68·5	137	Ba.
Bismuth	208	208	Bi.
Boron	11	11	B.
Bromine	80	80	Br.
Cadmium	56	112	Cd.
Cæsium	133	133	Cæ.
Calcium	20	40	Ca.
Carbon	6	12	C.
Cerium	46	92	Ce.
Chlorine	35·5	35·5	Cl.
Chromium	26	52·5	Cr.
Cobalt	29·4	58·8	Co.
Copper (Cuprum)	31·7	63·5	Cu.
Didymium	48	96	Di.
Fluorine	19	19	F.
Glucinum	7	14	G.
Gold	196·7	196·7	Au.
Hydrogen	1	1	H.
Iodine	127	127	I.
Iridium	99	198	Ir.
Iron (Ferrum)	28	56	Fe.
Lanthanum	46	92	Ln.
Lead (Plumbum)	103·5	207	Pb.
Lithium	7	7	Li.
Magnesium	12	24	Mg.
Manganese	27·5	55	Mn.
Mercury (Hydrargyrum)	100	200	Hg.
Molybdenum	46	92	Mo.
Nickel	29·4	58·8	Ni.
Niobium	48·8	97·6	Nb.
Nitrogen	14	14	N.
Osmium	99·5	199	Os.
Oxygen	8	16	O.
Palladium	53·2	106·5	Pd.
Phosphorus	31	31	P.
Platinum	98·7	197·4	Pt.
Potassium (Kalium)	39	39	K.
Rhodium	52	104	Ro.
Rubidium	85·5	85·5	Rb.
Ruthenium	52	104	Ru.
Selenium	39·5	79	Se.
Silicon	28·5	28·5	Si.
Silver (Argentum)	108	108	Ag.
Sodium (Natrium)	23	23	Na.
Strontium	43·7	87·5	Sr.
Sulphur	16	32	S.
Tantalum	68·7	137·5	Ta.
Tellurium	64	128	Te.
Thallium	204	204	Tl.
Thorium	115·7	231·5	Th.
Tin (Stannum)	59	118	Sn.
Titanium	25	50	Ti.
Tungsten	92	184	W.
Uranium	60	120	U.
Vanadium	68·5	137	V.
Yttrium	34	68	Y.
Zinc	32·5	65	Zn.
Zirconium	45	90	Zr.

It will be understood that the above symbols represent a single atom of each of the simple bodies, in reference to hydrogen as *unity*. Thus, on the old system of notation H represents 1 part by weight of hydrogen; O, 8 parts by weight of oxygen; S, 16 of sulphur; Hg, 100 of mercury, and so on. It is evident, however, that, as far as these combining proportions are concerned, other numbers or weights, bearing the same relations to each other, might be adopted: thus upon the *oxygen* scale, oxygen is represented as = 100; in which case hydrogen is 12·50, sulphur 200, mercury 1250, &c. But we shall confine ourselves exclusively to the hydrogen scale, which is now in most general use, and is in all respects preferable to the more complicated numbers which the oxygen scale necessarily involves.

When two or more atoms of one elementary substance are to be indicated, figures are placed either before or after the symbol. Thus, 2 atoms of iron may be represented by 2 Fe, or by Fe_2; in the former case a large, in the latter a small numeral being generally adopted. It is customary to place this small numeral

somewhat above or below the symbol, as Fe^2, or Fe_2. For further information on this subject, see NOTATION, CHEMICAL.

Symbols, Zoological. The symbols referring to sex and size are the same as in botany, the former being most commonly used in the description of insects. Those indicative of particular teeth and their arrangement are restricted in use to diphyodont mammals: they consist of the initial letters of the following kinds of teeth: *i.* incisors, *c.* canines, *p.* premolars, *m.* molars. When teeth of these kinds belong to the first or deciduous series, the letter *d* is prefixed: the individual tooth of each kind is indicated by an added numeral. The numbers and relative position of each kind of teeth in any given genus of diphyodont, are indicated by formulæ of the following kind:—

$$d.i.\frac{3-3}{3-3},\ d.c.\frac{1-1}{1-1},\ d.m.\frac{4-4}{4-4} = 32.$$

$$i.\frac{3-3}{3-3},\ c.\frac{1-1}{1-1},\ p.\frac{4-4}{4-4},\ m.\frac{3-3}{3-3} = 44.$$

These show the numbers and kinds of teeth, in both first and second dentitions, of the hog (*Sus*). The kinds of teeth follow each other in the jaw, from before backward, as their symbols are written from left to right; the numerals above the line indicate those of the upper jaw, the numerals below the line those of the lower jaw: the numbers of each kind of teeth, on the right and left sides of both upper and lower jaws, are indicated by the connecting dash. This symbolism or notation shows that the deciduous dentition of the genus *Sus* includes the following teeth on each side of both jaws, viz. three incisors, one canine, and three molars, the total number being thirty-two: the permanent dentition similarly includes three incisors, one canine, four premolars, and three molars, the total number being forty-four. The individual teeth, in each series of several, are symbolised as they follow one another from before backward, the incisors as *i.*1, *i.*2, *i.*3, the premolars as *p.*1, *p.*2, *p.*3, *p.*4, the molars as *m.*1, *m.*2, *m.*3. Each of these teeth in the hog may be distinguished from the rest; and if, among the fossil remains of an extinct species, $m.\overline{3}$ is said to be found, the symbol implies it to be the third or last molar of the upper jaw; $m.\underline{3}$ in like manner symbolises the third molar of the lower jaw, and so of the other symbols of individual teeth according to their relative position, vertically, to the added line. As the first of the four premolars in the hog appears to be the first of the deciduous series unshed, or retained, it may be symbolised as *d.m.*1.

The permanent dental formula of the dog (*Canis*) is:—

$$i.\frac{3-3}{3-3},\ c.\frac{1-1}{1-1},\ p.\frac{4-4}{4-4},\ m.\frac{2-2}{3-3} = 42.$$

The tooth in the dog's dentition here wanting is *m.*3.

The following are the formulæ of the human deciduous and permanent dentitions:—

$$d.i.\frac{2-2}{2-2},\ d.c.\frac{1-1}{1-1},\ d.m.\frac{2-2}{2-2} = 20.$$

$$i.\frac{2-2}{2-2},\ c.\frac{1-1}{1-1},\ p.\frac{2-2}{2-2},\ m.\frac{3-3}{3-3} = 32.$$

The teeth of the porcine formula here wanting are, *d.i.*3, *d.m.*1, and *d.m.*2; and, in the second set, *i.*3, *p.*1, and *p.*2. Respecting the missing incisor there may be a doubt, but none as to the premolars: the teeth called *bicuspids* in anthropotomy are the homologues of *p.*3 and *p.*4 in the typical diphyodont dentition.

In Ichthyology, the characters afforded by the fin-rays, whether of texture or number, are symbolised by letters and numerals with the sign *plus*. In the Perch (*Perca fluviatilis*) e.g. they are thus noted:—

D.15, 1 + 13 : P.14 : V.1 + 5 : A. 2 + 8 : C.17

signifying that there are two dorsal fins, D, of which the first has fifteen rays, all hard or spinous, the second has one spinous *plus* thirteen that are soft: P, the pectoral fin, has fourteen rays, all soft: V, the ventral fin, has one spinous *plus* five soft rays: A, the anal fin, has two spinous *plus* eight soft rays: C, the caudal fin, has seventeen rays.

Symbolism. The name applied to the system which invested the forms of Christian architecture and ritual with a symbolical meaning. The extent to which this symbolism was carried has been a subject of much controversy. Specimens of such interpretation may be found in the writings of Hugh of St. Victor; but the system was carried out to its utmost extent in the *Rationale Divinorum Officiorum* by Durandus, bishop of Mende, in the thirteenth century. (Didron, *Iconographie Chrétienne.*)

Symmetric Functions. In Algebra, a function of two or more quantities is said to be symmetric with respect to those quantities if, independently of their particular values or any relation subsisting among them, the function is unaltered when any two of the quantities whatsoever are interchanged. Thus, the function

$$ab + cd + ce + de$$

is symmetric with respect to *c*, *d* and *e*; for it is unaltered (except in the order of the terms) when we interchange *c* and *d*, or *c* and *e*, or *d* and *e*; it is also symmetric with respect to *a* and *b*, but not with respect to *a* and *c*, or *a* and *d*, or *a* and *e*, or with respect to *b* and *c*, or *b* and *d*, or *b* and *e*. The expression

$$ab + ac + ad + ae + bc + bd + be + cd + ce + de$$

is symmetric with respect to all the letters *a*, *b*, *c*, *d* and *e*; for there is no interchange of any two letters that will alter the function. So also the expression

$$abcd + abce + abde + acde + bcde$$

is a symmetric function of the same five letters.

The sums, differences, products, quotients, powers, and roots of symmetric functions are themselves symmetric functions, provided all the functions combined by addition, subtraction, &c., contain the same indeterminate magnitudes, and in the same number. Thus, the expression

$$\frac{(ab+ac+bc)^m + \sqrt[n]{abc}}{\sqrt[p]{(abc-a-b-c)}} + \frac{abc}{\frac{1}{a^2}+\frac{1}{b^2}+\frac{1}{c^2}}$$

is a symmetric function of a, b and c, because $ab+ac+bc$, abc, $a+b+c$, and $\frac{1}{a^2}+\frac{1}{b^2}+\frac{1}{c^2}$ are severally symmetric with respect to these three letters.

It is often found convenient to represent symmetric functions by prefixing the symbol Σ to one of the terms of the symmetric function; this term is taken as a type of all the others, and the prefixed Σ denotes the sum of the terms. Thus, let there be n quantities x_1, x_2, x_3 . . . x_n, then the sum of their m^{th} powers, which is a symmetric function, viz.

$$x_1^m + x_2^m + x_3^m + \ldots + x_n^m,$$

is represented by Σx_1^m, or, more simply, by Σx^m. In like manner, the symmetric function

$$x_1^m x_2^p + x_1^m x_3 + x_2^m x_3^p + \ldots + x_{n-1}^m x_n^p,$$

formed by the permutation of the n quantities taken two at a time, and by writing the exponent m over the first quantity, and p over the second in each term, is denoted by $\Sigma x_1^m x_2^p$, being the sum of all the terms which can be formed like $x_1^m x_2^p$.

The coefficients of an equation are symmetric functions of the roots of the equation. Let x_1, x_2, x_3 . . . x_n be the roots of the equation

$$x^n + ax^{n-1} + bx^{n-2} + cx^{n-3} + \ldots = 0,$$

then

$$-a = \Sigma x_1, b = \Sigma x_1 x_2, -c = \Sigma x_1 x_2 x_3, \text{\&c.}$$

In general, any rational symmetric function of the roots may be expressed rationally in terms of the coefficients of the equation. In the *Algebra* of Meyer Hirsch are given some very useful tables of the symmetric functions up to the tenth degree of the roots of an equation of any order. By means of these tables any symmetric function of the roots, not exceeding ten dimensions, being given, its value in terms of the coefficients of the equation becomes immediately known. Prof. Cayley, in a memoir entitled 'On the Symmetric Functions of the Roots of an Equation,' published in the *Philosophical Transactions* for 1857, has recalculated and corrected Hirsch's tables, and joined to them another set, giving reciprocally the expressions of the powers and products of the coefficients in terms of the symmetric functions of the roots. In the *Cours d'Algèbre Supérieure* (1866) of J. A. Serret, the subject of symmetric functions is treated with great elegance.

Symmetrical Determinant. A determinant in which those constituents are equal which are symmetrically situated with respect to the principal diagonal. An example is presented by the important function known as the discriminant of the ternary quadric $(a, b, c, d, e, f \between x, y, z)^2$ which, expressed as a determinant, is,

$$\begin{vmatrix} a & f & e \\ f & b & d \\ e & d & c \end{vmatrix}$$

If S denote any such determinant, and $a_{i,k}$ the k^{th} constituent of its i^{th} row, then $a_{i,k} = a_{k,i}$. The determinant $S' = S^{n-1}$ of the reciprocal system is also symmetrical; and if $a'_{i,k}$ represent the element of S', which corresponds to $a_{i,k}$ in S, we have $a'_{i,k} = a'_{k,i}$ $= \frac{1}{2}\frac{dS}{da_{i,k}}$. [DETERMINANTS.]

Symmetrical Figures. In Geometry, two points are said to be symmetrical with respect to a third point, the *centre of symmetry*, when the former are equidistant from, and in the same straight line with, the latter. Two points are also said to be symmetrical with respect to a given line, *axis of symmetry*, when they are equidistant from the latter and situated on the same perpendicular to it. Lastly, two points are said to be symmetrical with respect to a given *plane of symmetry*, when they lie on the same perpendicular to this plane and are also equidistant from the latter. Similarly, two *figures* are said to be symmetrical with respect to a centre, an axis, or a plane when their points taken in pairs are so. A figure and its reflected image are symmetrical with respect to the plane of the mirror. Two figures which are symmetrical with respect to an axis can always be superposed by causing one to make half a complete rotation about that axis. When the figures are symmetrical with respect to a centre or a plane they cannot in general be superposed, though their rectilineal edges, as well as their plane and dihedral angles, are equal two and two. The volumes of two such symmetrical solids are likewise equal. Two spherical triangles whose corners are diametrically opposed to each other are symmetrical with respect to the centre of the sphere. When each is isosceles, they can be superposed, but not otherwise; nevertheless, their angles and sides are always equal, as are also their areas. Two figures which are symmetrical to the same figure, with respect to two different centres or planes of symmetry, are equal and superposable. An interesting memoir on symmetrical figures by Bravais will be found in Liouville's *Journal*, 1849. Legendre, in the sixth book of his *Eléments de Géométrie*, defines symmetrical polyhedra and examines their properties.

Symmetrical Skew Determinant. [DETERMINANTS; SKEW SYMMETRICAL DETERMINANTS.]

Symmetry (Gr. συμμετρία, *proportion*, literally *a measuring together*). In Botany, that kind of arrangement in which the number

of parts of one series corresponds with that of the other series; as, for example, when a flower with five sepals has five petals, and five or ten or fifteen stamens.

Symmetry. In the Fine Arts. [Proportion.]

Symmoria. [Trierarchia.]

Sympathetic Inks. Liquids which are colourless or so slightly coloured that characters written with them are invisible till acted upon by some reagent. The best is a dilute solution of chloride of cobalt. Markings made with it become blue when the paper on which they are written is held in front of a fire, the slightly tinted pink hydrated salt then becoming anhydrous and deeply blue.

Sympathetic Nerve. This term is applied, in Anthropotomy, to a system of nerves, which in the Vertebrate series consists of one or more ganglia, usually a series of such, arranged on each side of the bodies of the vertebræ from the occiput to the anterior caudal vertebræ. Where the ganglia are numerous, each lateral series is connected by a band of nervous fibres, and they resemble a pair of gangliated cords. They communicate with the contiguous spinal nerves, and with cranial nerves through small ganglia in different parts of the head. At the caudal end the two *sympathetic nerves* or cords unite with a single ganglion.

A *sympathetic ganglion* is a body connected with bundles of nerve-fibres, the chief proceeding to or from it in the direction of its axis, the smaller nerves diverging more or less transversely. It consists of corpuscles called *ganglion-vesicles*, and of nerve-fibres embedded in a nucleated fibrous tissue.

The nerves from the sympathetic system are principally disposed in plexuses, the chief of which, in man, are the *cardiac*, the *solar*, and the *hypogastric*; there are many minor plexuses, of which those, like the *carotid*, surrounding the arteries by the *nervi molles*, are very characteristic of the sympathetic system. The nerves from the abdominal plexuses are so distributed that the intestinal canal is under its direct influence, and indirectly to that of the myelencephalic system. Some experiments seem to show that the sympathetic nerves have more influence upon the nutritive processes than the sensory ones. The normal contraction of arteries appears to be excited by the sympathetic nerves distributed to their walls. The old name relates to a fanciful phase of physiology.

Sympathy (Gr. συμπάθεια, *fellow-feeling*). In the Fine Arts, this term signifies conformity of the parts to each other; but in Painting it is more usually applied to the effective union of colours.

Sympathy. In Moral Philosophy, the quality of being affected by feelings common to our fellow-men. In his *Theory of Moral Sentiments*, Adam Smith maintains that sympathy is the real foundation of morals. [Ethics.] For a succinct statement of this theory, see 'The Life of Adam Smith,' prefixed to M'Culloch's edition of the *Wealth of Nations*, p. iv.

Symphony (Gr. συμφωνία, from φωνή, *sound*). In Music, a composition which, from the etymology of the term, evidently implies that the voice anciently formed an essential part of its construction. In the present day, however, the term is otherwise applied, and is exclusively used for a piece in which instruments only are engaged. It is, in fact, a composition for a perfect instrumental orchestra, which until the beginning of the eighteenth century was unknown. The *concerti grossi* of Corelli were the first of the species. The idea was carried out to a greater extent in the works of Geminiani and Vivaldi; but before the time of Haydn it can scarcely be said to have assumed the form which the name now imports. There is, perhaps, no musical composition in which the power of the author is so completely developed as in a symphony. The musician in it becomes a poet, or perhaps rather a painter. Scenes and the passions are represented by a combination of musical sounds; as an illustration, we need only cite that splendid work of Beethoven known to all under the name of *Il Pastorale*. The general form of the symphony may be thus described: It opens with a short, serious, slow movement; this is followed by and forms a contrast to one of spirit and of a lively nature; then comes an andante varied, or an adagio or slow movement; a minuet with its trio follows; and the symphony usually closes with a lively rondo, or a finale of rapid motion.

Symphysis (Gr. σύμφυσις, *a growing together*). A term applied to the junction of certain bones, or to joints not admitting of motion; as the *symphysis of the pubis*.

Symphytum (Gr. σύμφυτον, *planted together with*). A genus of *Boraginaceæ*, inhabiting Europe and Central Asia, and consisting of coarse-growing perennials, with scorpioid racemes of rather large pale-yellow, purple, or blue flowers. Our native species, *S. officinale*, the Comfrey, is a well-known plant of water-courses, having much the taste and properties of borage, for which it was not unfrequently substituted in the old English cool tankard, and amongst herbalists it was highly extolled as a 'cooler of the blood.' *S. asperrimum*, a species from the Caucasus, has been much recommended as a green *soiling* plant for cattle, and is capable of producing large crops, two in the season, amounting, perhaps, to from forty to fifty tons of green food per acre. Its cultivation is easy. Divisions of its suckers may be planted in rows two feet apart, with fully a foot between each of the plants in the rows. It may be cut twice, and will yield largely, especially if some rotten dung be dug in between the rows when the plantation is dressed up for winter.

Sympiezometer (Gr. συμπιέζω, *I compress*; μέτρον, *measure*). An instrument contrived by Mr. Adie of Edinburgh for measuring the weight of the atmosphere by the compression of a column of gas. It consists of a glass tube

ABC of about 18 inches in length, bent as represented in the annexed figure, and having an enlarged portion or bulb of about 2 inches in length and half an inch in diameter at each end. The top at A is hermetically sealed, and the other extremity C can be stopped by a cork. The upper part of the tube A m is filled with some permanently elastic gas different from common air (hydrogen gas is found to answer best), and the lower m B n with a fixed oil, or with some fluid which does not act upon the gas and is not acted upon by air.

The tube being open at C, the oil is exposed to the pressure of the atmosphere, and stands at a height m, corresponding to the difference of the pressures of the atmosphere and of the column of enclosed gas. Consequently, as the atmospheric pressure becomes greater the gas will be compressed, and the column of oil will rise. The change in the bulk of the gas occasioned by a change of pressure is measured by a scale, which is formed experimentally, and of which the divisions are entirely arbitrary.

But the as bulk of the enclosed gas is altered by any change of temperature as well as of pressure, it is necessary to apply a correction on this account. For this purpose a common thermometer is attached to the instrument to indicate the temperature; and the principal or barometric scale, which measures the compression of the gas, is made to slide upon another scale so divided as to represent the change of bulk in the gas produced by a change of temperature under the same pressure, and corresponding to the graduation of the thermometer. In making an observation, the temperature is first observed by the thermometer; an index or pointer, which is fixed to the top of the sliding scale, is then set opposite to the degree of temperature on the fixed scale, and the number on the sliding scale opposite the top of the column of oil gives the pressure of the air in inches of the mercurial barometer.

The principle of the sympiezometer is the same as that of the MANOMETER, or air barometer, which was long ago proposed by Hooke.

Symplesite (Gr. συμπλησιάζω, *to draw close together*). A hydrated arseniate of protoxide of iron, which is found at Klein-Friesa in Reuss.

Symposiarch (Gr. συμποσίαρχος, from συμπόσιον, *a feast*, and ἄρχω, *I rule*). The ruler or master of a feast, selected by the consent of the party to be their president for the occasion; he was sometimes called βασιλεύς. The word rendered *governor of the feast*, in John ii. 8, is ἀρχιτρίκλινος.

Synoecia (Gr. συνοίκια, from σύν, *with*, and οἰκέω, *to dwell*). In Classical Antiquities, an Athenian festival in commemoration of the union of the little townships of Attica into one commonwealth. This consolidation of independent demi [DEMOS] into a single state was attributed to the mythical hero THESEUS.

Synaeresis (Gr. συναίρεσις, *a taking together*). Otherwise called *crasis* (Gr. κρᾶσις, *a mixture*). In Grammar, the contraction of two syllables into one by the formation of a diphthong, or by rendering one of them mute; as, Atreides for Atreïdes. [METAPLASM.]

Synagogue (Gr. συναγωγή, *a gathering*). The religious assemblies of the Jews are so called by Hellenic writers. The Jews had no synagogues, it is thought, before the Babylonish captivity. They were first formed after the return of the Jews to the Holy Land. The rule was, that a synagogue was to be erected in any place where there were ten persons of full age and free condition ready to attend the service of it. Others, however, consider the ten *batelnim*, to use the Hebrew word, to have been ten elders, or stationary men of the synagogue. (Lightfoot.) The service performed in the synagogues consisted, and still consists, of prayers, reading the Scriptures, Biblical exposition, and preaching. The prayers are contained in liturgies. The reading of the Scripture consists of three portions: the 'Shema,' certain selected passages from Deuteronomy and Numbers; the law; and the prophets. The third part of the service is mentioned in several places in the Gospel narratives and in the Acts. (Luke iv. 16, Acts xiii. 5.) The times of the synagogue service were three days a week (Monday, Thursday, and Saturday), besides the holy-days. The ministration of the synagogue was not confined to the order of priests; the elders, or *rulers of the synagogue*, were persons qualified, and duly admitted, from all tribes. (Prideaux, *Connection*, vol. i.)

Synalaepha (Gr. συναλοιφή, from ἀλείφω, *I anoint*, from the melting together of two sounds). In Classical Prosody, the usage by which, when a word ends with a vowel, and the next begins with a vowel, the final syllable of the one runs into the first of the other. This, in Latin verse, also takes place when the last letter is *m*; but the usage in this instance is called *ecthlipsis*, or elision. The synalæpha is commonly, though not with equal regularity, adopted in Italian and Spanish poetry, and is not unfrequently attempted, especially by Milton, in our own; in French it extends only to the *e* mute at the end of words.

Synaptase. *Emulsin*. A ferment existing in almonds. It has the power of breaking up amygdalin into oil of bitter almonds, formic acid, hydrocyanic acid, and sugar; and salicin into sugar and saligenin.

Synarthrosis (Gr. συνάρθρωσις, from ἄρθρον, *a joint*). The immovable connection of one bone with another.

Syncarpium (Gr. σύν, and καρπός, *fruit*). In Botany, a fruit consisting of many carpels consolidated and adhering to a central receptacle or growing point, as in *Magnolia*.

Syncarpous (Gr. σύν, and καρπός). In Botany, a term applied to the carpels of a compound pistil when they are completely

united into an undivided body; as in the Orange.

Syncategorematic (Gr. συγκατηγορηματικός, from σύν, and κατηγόρημα; a word employed together with categorematics or terms). In Logic, a word which cannot be employed by itself as a term, but must be conjoined with another or others for that purpose. Such are adverbs, prepositions, nouns in other cases beside the nominative, &c. [TERM.]

Synchondrosis (Gr. συγχόνδρωσις, from χόνδρος, *a cartilage*). The junction of one bone with another by an intervening cartilage.

Synchronism (Gr. συγχρονισμός). The tabular arrangement of history according to dates, by which contemporary persons and things in different countries are brought together. [TABULATION OF CHRONOLOGY.]

Synchronous Curve. In Mechanics, a curve which would be reached in the same time by a body or material particle falling from a given point down any one of a set of given curves belonging to the same family. Thus, if from a fixed point on an inclined plane right lines be drawn, and down the several lines particles, starting together, be conceived to fall, they will all, at any subsequent instant, be situated on the circumference of a circle which touches the *level line* at the common starting-point. This circle is the *synchronous curve* of the system of right lines. The property in virtue of which coinitial chords of a circle are described in equal times is frequently referred to as the *synchronism of the circle*.

Synclinal. [ANTICLINAL AND SYNCLINAL AXIS.]

Syncopation. In Music. [DRIVING NOTES.]

Syncope (Gr. συγκοπή, from κόπτω, *I cut*). A figure of Grammar, by which one or more letters are omitted in the middle of a word; as in the Latin *litus* for *littus*. [METAPLASM.]

SYNCOPE. In Music. [LEGATO.]

SYNCOPE. In Pathology, fainting. A disease in which the circulation and respiration temporarily cease or become extremely feeble.

Syncretism (Gr. συγκρητισμός). In Philosophy, the blending of the tenets of different schools into a system. A party among the Platonists at the revival of letters, to which belonged Ammonius, Pico della Mirandola, Bessarion, and other distinguished men, have received the name of Syncretists.

Syncretists. In Ecclesiastical History, the partisans of George Calixtus, a Lutheran divine of the sixteenth century, who endeavoured to form a comprehensive scheme which should unite the different professors of Christianity. The opinions of Calixtus raised a strong controversy in the Lutheran church. A new confession of faith was drawn up in Saxony for the purpose of excluding his partisans. His doctrines, however, did not long survive his death, although they were not without effect on the spirit of the age.

Syndactyles (Gr. σύν, and δάκτυλος, *a finger*). The name of a tribe of Perchers, including those which have the external and middle toe united as far as the second joint.

Syndesmosis (Gr. σύνδεσμος, *a ligament*). The union of one bone with another by means of ligament.

Syndic (Gr. σύνδικος, from δίκη, *justice*). A title given at different times to various municipal and other officers. The syndics of cities in Provence and Languedoc, under the old French government, were officers delegated by the municipality as agents or mandatories. Such were also the syndics of trading companies. The creditors of a bankrupt, under the law of France, appoint syndics or directors from among their number.

Synecdoche (Gr. συνεκδοχή, from σύν, *with*, ἐκ, *out*, and δέχομαι, *I receive*). In Rhetoric, a figure by which the whole is put for a part, or part for the whole. It is a species of TROPE. There are six ordinary instances of synecdoche: 1. When genus is put for species (as *being* in the sense of *man*). 2. When species is put for genus. 3. When the essential whole is put for one of its parts. 4. When the matter, or form, is put for the whole being. 5. The whole for a part. 6. The part for the whole.

Synechia (Gr. συνέχεια, *continuity*). A disease of the eye in which the iris adheres to the cornea, or to the capsule of the crystalline lens.

Synedrous (Gr. σύνεδρος, *sitting with*). In Botany, a term applied in those cases when the leaves or other parts grow on the angle of a stem.

Synergists (Gr. συνεργός, *working together*). A name given to a party in the Lutheran church in the latter end of the sixteenth century. Those who were thus called appear to have held the doctrine that the divine grace requires a correspondent action of the human will in order to become effectual; which, or something resembling it, is termed *semi-Pelagian* in early ecclesiastical history. Some sentiments expressed by Melanchthon, towards the close of his life, seem to have introduced it into that church. [PELAGIANISM.]

Syngenesious (Gr. σύν, and γένεσις, *birth*). In Botany, a term applied to flowers having the anthers united at their edges, so as to form a tube.

Syngnathians (Gr. σύν, and γνάθος, *a jaw*). The name of a family of Lophobranchiate fishes, including those in which the lengthened jaws are united by a surrounding integument, so as to form a tubular mouth: the genus *Syngnathus*, or pipe fish, is the type. *Syngnathæ* is a name given by Dr. Leach to an order of Myriapodous insects.

Syngrapha (Gr. σύγγραφος, from γράφω, *I write*). In Diplomatics, contracts signed by the creditor and debtor, and of which a duplicate original was kept by each.

Synizesis (Gr. συνίζησις). An obliteration of the pupil of the eye; a closed pupil.

SYNIZESIS. In Grammar, this term is used to denote the melting of two vowels into one.

Synneurosis (Gr. *συννεύρωσις*, from *νεῦρον*, *a nerve* or *membrane*). The union of one bone with another by means of an intervening membrane.

Synocha (Gr. *σύνοχος*, *joined together*). The old name for continued inflammatory fever. The term *synochus* was applied to continued fevers, which were in their symptoms intermediate between *synocha* and *typhus*. They were called *mixed fevers*.

Synod (Gr. *σύνοδος*, *an assembly*). In Ecclesiastical language, this term denotes the convention of the inferior clergy of a diocese by its bishop or archdeacon. [Council.]

Synod. In the Scottish Kirk, an assembly composed of two more presbyteries. It consists of every parish minister within its limits, and of the elders who have last represented the different sessions in the presbytery. There are sixteen synods in Scotland. [Presbytery.]

Synod of Dort. [Dort, Synod of.]

Synodic. In Astronomy, the synodic revolution of a planet (or the moon), with respect to the sun, is the time between two consecutive conjunctions or oppositions. The duration of this period is easily found when the difference between the mean motion of the planet and the sun in a given interval of time is known; for this difference is to 360° as the given interval to the synodic revolution. The *synodical month* is the period of the moon's synodic revolution, and is the same with *lunar month* or *lunation*. [Moon.]

Synodic Month. [Lunar Month.]

Synonyms (Gr. *συνώνυμος*, from *ὄνομα*, *a name*). Words of the same language which have a similar signification. Strictly speaking, words having exactly the same signification are not to be found in any language, unless one of them has been borrowed from another language; but in this case the shades of difference are often so slight that words may be frequently used for one another, and this interchange produces a pleasing variety in composition, necessary in poetry. The chief works on this subject are the *Onomasticon* on Greek, Dumesnil on Latin, Blair, Crabbe, and Taylor on English, Stosch and Eberhard on German, and Giraud, Beauzée, Roubaud, and Guizot on French synonyms.

The multiplication of synonyms was a main cause of the growth of myths. In the mythopœic ages there was a constant tendency to devise names denoting each of the attributes of any given object, and thus the names of prominent phenomena in the outward world would be as numerous as the aspects which from time to time they might assume. Gradually the greater portion of these names would become useless, until at last the literary dialect would choose out some one of them to denote the object to the exclusion of the rest. The more ancient languages are therefore the richest in synonyms.

These synonyms, if used constantly, 'must naturally give rise to a number of homonymes. If we call the sun by fifty names expressive of different qualities, some of these names will be applicable to other objects also, which happen to possess the same quality. These different objects would then be called by the same name—they would become homonymes.' (Max Müller, *Comparative Mythology*, 45.) [Polyonymy.]

Synopsis (Gr. *σύνοψις*, *a seeing together*). A collective view of any subject; as a synopsis of astronomy, theology, &c.

Synoptic (Gr. *συνοπτικός*, *seeing at a glance*). In Biblical criticism, this term is sometimes used to distinguish the first three Gospels, as containing generally the same succession of events, from the fourth, in which the narrative and the discourses are not the same as those given in the other Gospels.

Synovia (Gr. *σύν*, and *ὠόν*, *an egg*). The fluid which lubricates the cartilaginous surfaces of the joints: it is glairy, and resembles the white of egg.

Syntax (Gr. *σύνταξις*, from *συντάσσω*, *I arrange together*). In Grammar and Rhetoric, the disposition of the words and members of a sentence in the grammatical arrangements proper to the language. [Grammar.]

Synteleia. [Trierarchia.]

Synthesis (*σύνθεσις*, from *συντίθημι*, *I place together*). In Chemistry, those chemical operations by which compounds are obtained by the union of the separate component parts are called *synthetic*. The term is especially used as opposed to *analysis*. Thus, we demonstrate the composition of water *analytically* by resolving it into oxygen and hydrogen gases; and *synthetically*, by recombining those gases so as again to produce the water which had previously been decomposed; the terms *synthesis* and *analysis* being, in fact, synonymous with *composition* and *decomposition*.

Synthesis. In Geometry and Logic, the method of demonstration which sets out from some principle established or assumed, or from a proposition already demonstrated, and ascends through a series of propositions to that which is enunciated. Synthesis is also called the direct method or *composition*, and is the reverse of analysis or resoluion. It is the method followed in Euclid's *Elements*. For the sense in which analysis and synthesis were understood by the ancient geometricians, see Analysis.

Syphilis (perhaps coined from Gr. *σιφλός*, *crippled, defective*). The venereal disease.

Syphon. [Siphon.]

Syringa (Gr. *σῦριγξ*, *a pipe* or *tube*). A favourite genus of *Oleaceæ*, of which familiar examples occur in the various Lilacs of our gardens. The native country of some of these is not well ascertained, although the genus appears to be confined to South-eastern Europe and Central and Eastern Asia. They are deciduous shrubs with entire leaves, and terminal more or less pyramidal panicles of usually sweet-smelling flowers. The Common Lilac, *S. vulgaris*, is the largest species and also one of the most familiar and most beautiful of our spring-

flowering ornamental shrubs. The Persian Lilac, *S. persica*, is smaller, seldom growing more than six or eight feet high. There are several garden varieties of the different kinds of Lilac.

Syringe (Gr. σῦριγξ). In Hydraulics, a machine consisting of a small cylinder with an air-tight piston or sucker, which is moved up and down in it by means of a handle. The lower end of the cylinder terminates in a small tube, through which a fluid is forced into the body of the cylinder by the atmospheric pressure when the handle is drawn up, and then expelled in a small jet by pushing the handle in the opposite direction. The syringe acts on the principle of the sucking pump. The syringe is also used as a pneumatic machine for condensing or exhausting the air in a close vessel, but for this purpose it must be furnished with two valves. In the condensing syringe, the valves open downwards and close upwards; in the exhausting syringe they are closed downwards and opened upwards. [AIR GUN; AIR PUMP.]

Syringine. A crystallisable bitter principle obtained from the leaves of the lilac-tree (*Syringa vulgaris*). It has also been called *lilacine*.

Syrma (Gr. σύρμα, from σύρω, *I draw*). A long garment; so called from its train reaching the ground. It was the proper dress of actors in the classical tragedy.

Syssarcosis (Gr. συσσάρκωσις, from σάρξ, *flesh*). The junction of bones by intervening muscles.

Syssitia (Gr. συσσίτια, *common messes*). An institution of some ancient states, particularly Lacedæmon and Crete, which ordained that the male freemen should have their meals together in common messes, instead of eating with their families in private. [LIBERTY.]

System (Gr. σύστημα). In Astronomy, an hypothesis of a certain order and arrangement of the celestial bodies by which their apparent motions are explained. For an account of the systems of Ptolemy, Copernicus, and Tycho Brahe, see ASTRONOMY.

SYSTEM. In the Fine Arts, a collection of the rules and principles upon which an artist works. [DECORATION.]

SYSTEM. In Music, an interval composed, or supposed to be composed, of several lesser ones; as an octave, which is a system. [DIASTEM.]

Systemic. In Physiology, this word is applied to designate the circulation of the general system, beginning at the left ventricle and aorta, and ending at the venæ cavæ and right auricle, as contradistinguished from the circulation through the lungs, which is called *pulmonic*. They have also been termed the *greater and lesser circulations*. The parts concerned in these circulations have also received the same names: thus, the left ventricle is called the *systemic* one.

Systole (Gr. συστολή, from συστέλλω, *I contract*). In Greek and Latin prosody, a license by which a long syllable is used as short: e.g.

Matri longa decem tulĕrunt fastidia Menses.

SYSTOLE. In Medicine, the contraction of the heart.

Systyle (Gr. σύστυλος). In Architecture, the arrangement of columns in such a manner that they are two diameters apart.

Syzygetic Function (Gr. σύζυγος, *yoked together*). According to Prof. Sylvester, with whom the term originated, a syzygetic function of a set of given, rational, integral functions is the sum of the products obtained by multiplying each of the latter by another arbitrary function. The multipliers are termed the *syzygetic multipliers*, and the original functions are said to be *syzygetically related* when a syzygetic function of them can be made to vanish. (*Phil. Trans.* vol. cxliii. pt. ii. 1853.)

Syzygies (Gr. συζυγία, *conjunction*). In Astronomy, the places of the moon or planets when in conjunction or opposition with the sun.

Szajbélyite. A native hydrated borate of magnesia lately discovered by K. Peters, in limestone, at Workesthal, near Rezbanya.

Named after the royal mining officer Szajbélyi, of Rezbanya, in Hungary.

T

T. A letter belonging to the class called *mutes*. It is susceptible of numerous interchanges, both in the ancient and modern languages. (Max Müller, *Lectures on Language*, second series iii.) As an abbreviation, T. was used for Titus, Ti. for Tiberius.

T Bandage. A bandage so named from its shape; it is used to support the dressings after certain surgical operations.

Taag. The Bengal or Sunn Hemp, *Crotalaria juncea*.

Tabard. In Heraldry, a garment worn by the knights of the Tudor era. It consisted of a short frock with wide sleeves reaching to the elbows, with the arms of the wearer displayed on the back and front. It is still worn as the official dress of heralds.

Tabasheer or **Tabachir** (Pers.). A substance secreted in the joints of bamboos, in bluish-white masses with a pearly lustre, and mainly composed of silicious matter which the plant is unable to incorporate in its tissues.

It is reputed to possess tonic properties, and has peculiar optical properties, which have been investigated and described by Sir David Brewster.

Tabby (Fr. tabis, Ital. tabi). A term formerly applied to certain figured silks and other goods upon which an irregular pattern had been stamped, either by the pressure of engraved rollers, or by folding the stuffs in such a way as to produce, by the mutual pressure of their fibres, an inequality of surface which, by reflected light, gives rise to the appearance called *watering*.

Tabellions (Lat. tabellio, from tabella, dim. of tabula, from the tablets on which they wrote). In the Roman empire, officers who had charge of public documents were so called; they were also secretaries, or registrars, and in some cases judges. (Savigny, *Hist. of the Roman Law*, vol. i.) The notaries were their assistants. In France, the titles of *tabellion* and *greffier* were confounded, and Henry IV. united the functions of tabellion with those of notary; but the old title seems still to be retained (or was until the Revolution) in some few places.

Tabergite. The name given to the Pyrosclerite of Taberg, in Wormland.

Tabernacle (Lat. tabernaculum, *a tent* or *cabin*). This name is applied especially to the tabernacle which the Jews are said to have carried from station to station during their wanderings in the desert; it is described as a tent of sails and skins stretched upon a framework of wood, and divided into two compartments; the outer, named *the Holy*, being that in which incense was burnt, and the shew-bread exhibited; and the inner, or *Holy of Holies*, in which was deposited the ark of the covenant. (Exod. xxvi. xxvii.)

The Feast of Tabernacles was one of the three principal festivals among the Jews. It commenced on the 15th of the month Tisri, corresponding with September 30, and lasted seven days, during which the people dwelt in booths formed of the boughs of trees. It was instituted in commemoration of the habitation of their ancestors in similar dwellings during the forty years of their pilgrimage in the wilderness. (Lev. xxiii.)

Tabernæmontana (after J. T. Tabernæmontanus, a celebrated botanist). An extensive tropical genus of *Apocynaceæ*, the numerous species of which are either shrubs or trees, with opposite entire leaves, false stipules, and cymes of fragrant yellow or white flowers, generally in pairs at the points of the branches. Like most other dogbanes, the *Tabernæmontanas* possess a milky juice; but the milk, instead of being exceedingly acrid and drastic like that of many allied genera, is, in some species at least, perfectly bland and wholesome. This is particularly the case with the Hya-Hya or Cow-tree of British Guiana, *T. utilis*, which, when tapped, yields a copious supply of thick sweet milk, resembling that of the cow in appearance, but rather sticky from the presence of caoutchouc. The tree yields a soft white wood; and its bark is used medicinally by the Indians.

Tabes (Lat.). In Animal and Vegetable Pathology, a wasting, or disease which consists in a gradual decay of the power of growth.

Tablature (Lat. tabula, *a table*). In Music, the use of the letters of the alphabet, or any other character, for expressing the notes or sounds of a composition. It is not now a usual mode of writing. In its stricter and more original sense it is a mode of writing music for a particular instrument on parallel lines (of which each represents a string of the instrument) by means of certain letters of the alphabet. Thus, A denotes that the string is to be struck open, B that one of the fingers is to be put on the first stop, C on the second, D on the third, and so on through the octave.

Table (Lat. tabula). In Astronomy, Physics, &c. This term has two different significations. In the first place, it is used to denote merely a collection of numbers, exhibiting the measures or values of some property common to a number of different bodies in reference to some common standard. Thus we have tables of specific gravity, of refractive powers, of the expansion of substances by heat, &c. In its second signification, it denotes a series of numbers which proceed according to some given law expressed by a mathematical formula. Of this kind are the logarithmic tables; tables of the powers or roots of the different numbers; of the sines, cosines, and other angular functions; of astronomical refractions; of the equations of the planetary orbits, &c. Tables of this sort, by exhibiting at once to the eye all the different values which a given formula can have, save endless labour in calculation, and are of the utmost importance in every branch of natural philosophy. The logarithmic tables, for example, form the universal instrument of astronomical calculation; and it may be safely affirmed that without them the computations necessary for determining the places of the different bodies of the solar system, and rendering astronomy a science of practical utility, would be altogether impossible.

Table is also used in a popular sense to denote a collection of particulars brought under one view. Thus, in history, we have chronological tables; in statistics, tables of mortality at different ages, &c. The mere titles of the useful tables which have been formed in the various departments of knowledge would fill a large volume.

Table Spar. [TABULAR SPAR; WOLLASTONITE.]

Table-lands or **Plateaux.** The plains of the great continents are some of them near the level of the ocean, while others are hardly less horizontal, but are elevated to a height of several hundred or even some thousand feet. Both may be broken or even undulating, and each may be connected with mountain chains. The latter are called *table-lands* or *plateaux*.

In Europe, the Iberian peninsula is a good example of table-land. Elevated from two to

three thousand feet, and having several chains of mountains rising out of it, this table-land produces the greatest possible modification of the climate, not only of the peninsula itself, but of all adjacent countries. It includes nearly 100,000 square miles of country. There are smaller plateaux in Central France.

Great plateaux exist in the Old World in connection with the great chain of mountains crossing Asia. One of these forms the table-land of Persia. There are others farther east, some of them far more extensive. They range, at various altitudes, from 5,000 to 15,000 feet, and are crossed by the spurs of the great mountain chains of the Altai and Himalaya. The table-lands of Central Asia are much less extensive than they were supposed to be by Humboldt, but they are still little known. There is an extensive plateau in Southern India.

In Africa there is table-land in the south, but the extent is not very great. In America a considerable plateau extends from Mexico to California, and there are some small plateaux of enormous elevation amongst the Andes. The table-land of Quito occupies about 6,000 square miles at an elevation of 10,000 feet. That of Desaguardero stretches 500 miles along the top of the Andes at an average height of 13,000 feet, and a breadth varying from 30 to 60 miles.

Of table-lands some are nearly level for great distances, but others undulate, and occasionally they form the basis of lofty mountain chains. In Europe the table-land is peninsular. In Asia it chiefly extends north of the mountain chain. In Africa there are tracts of high land of the nature of plateaux ranging round the coast from Abyssinia to the Cape, and again from the Cape to near the equator. In America the chief table-lands are amongst the mountains. Australia has very little table-land.

Tableaux Vivants (Fr. *living pictures*). The name given to an amusement in which groups of persons dressed are made to represent some scene in the works of distinguished painters or authors. It is thus managed: The room in which the spectators are placed being darkened, the group assume their respective attitudes behind a frame (or some other contrivance intended to represent it) covered with gauze; and candles being so placed as to reflect light upon the group from above, the illusion is complete. These representations are not unfrequently resorted to in England; but in France and Germany they form an important feature on all festive occasions. Tableaux are often employed to represent some scene in which a riddle is concealed.

Tablets. In Roman Antiquities, pieces of ivory, metal, stone, or other substance, used in judiciary proceedings, or in the passing of laws.

Taboo. A word used by the South Sea islanders to denote something sacred, or set aside for particular uses or persons.

Tabor (Old Fr. tabour). A small drum.

Taborites or **Thaborites.** The denomination of one of the parties into which the followers of Huss, in Bohemia, separated after the death of their leader. They were so called from Tabor, a hill of Bohemia, upon which they encamped during the struggle which they maintained against the civil and ecclesiastical power. At their head stood John Ziska, who was distinguished at once for his courage and cruelty. After a long struggle, the more quietly disposed portion of the Taborites formed themselves into a religious society under the denomination of the Bohemian Brethren. They established several Christian communities, elected their own bishops, priests, and elders; drew up a rigorous plan of ecclesiastical discipline; and sent forth missionaries to various parts. Though harassed by persecutions, they continued to increase in numbers, and at the end of the fifteenth century they counted about 200 communities of adherents. At the end of this period the distinctive name and opinions of the Taborites were lost among the various assailants of the Roman church, who formed the vanguard of the Reformation in Germany. [CALIXTINES; HUSSITES.] (Milman's *Latin Christianity*, book xiii. ch. xi.)

Tabular Spar. A silicate of lime, which sometimes occurs in distinct tabular prisms, but mostly in broad prismatic or laminar masses of a white tint inclining to yellow, green, red, or brown.

It is found in Scotland in the basalt of the Castle Rock, Edinburgh, and at Glengairn, Aberdeenshire; in Ireland at Dunmore Head, county Down; at Capo di Bove, near Rome, and in blocks ejected from Vesuvius, &c. &c. [WOLLASTONITE.]

Tabulation of Chronology. The arrangement of historical or professedly historical events according to their real or supposed dates is sometimes spoken of under this name. The value of such arrangements must be tested by contemporary historical documents: if for the period in question these are defective or wanting, the value of the arrangement is either lessened or destroyed; but in no case can a tabulation be of the slightest worth so long as it rests on mere conjecture or ingenious hypothesis apart from all contemporary evidence. Nor can a starting-point be gained from some event in a genuine historical period for a series of events in narratives which are contradictory, or of which the date of composition cannot be ascertained, or which contain narratives which are manifestly mythical or fabulous. Thus, because Herodotus, who is undoubtedly an historical person, expresses his belief that Homer lived about four hundred years before his own time, we are not warranted in inferring that there ever was any one poet so called, or that that poet composed the *Iliad* and the *Odyssey*, because Herodotus was not in possession of a continuous contemporary history from the time of the supposed Homer to his own. Far less are we warranted in assigning a date to the Trojan war, and to events which in the mythical cycle long precede the rape of Helen by Paris. Thus, when

Clinton in his *Fasti Hellenici* assigns the date B.C. 1753 to Phoroneus, he is really building a house on a foundation of sand, for he can only calculate back from the date of the Trojan war, which is obtained only by another retrospective calculation from some such point as the lifetime of Herodotus, and because, thus reasoning back from a narrative which is full of manifest fable, he reaches the story of a being like Phoroneus, whom he renders credible only by stripping him of all the raiment in which mythology has enwrapped him. Our whole acquaintance with Phoroneus is derived from legends which speak of him as the father of mortal men, who, like Prometheus, imparted to them the first notion of society and even the first knowledge of fire; among his children are Apis and Niobe, whose names at once carry us into the myths of Phœbus and Heracles. In short, for us, Phoroneus, who is none other than the Vedic god of fire, Bhuranyu, is neither more nor less real than the elephant which supports the world in the Hindu mythology; and to take his name and assign to it a date imparts no knowledge whatever, while it implies the conceit of knowledge without the reality.

It may be further asserted, that, if the mere name of Phoroneus with a date fails to make us acquainted with the time in which he lived, or even to assure us of his existence, any other lists which contain mere names and dates can possess no real historical value, unless they can be checked by contemporary historical narratives. Sir G. Cornewall Lewis maintains (*Astronomy of the Ancients*) that 'there is no example of history founded on contemporary registration being reduced to mere chronology,' and denies that we learn anything more from being told that Saites, Bnon, Pachnan, Staan, Archlês, and Aphobis were the six kings of Egypt in the fifteenth century B.C. than we should learn from an authentic account of the succession of a breed of crocodiles or hippopotami in the Nile, or of a series of sacred apes in a temple for the same period.'

The case is not substantially altered when, as by recent explorers in Mesopotamia, the names of a number of Assyrian and Babylonish kings are recovered from inscribed bricks and cylinders. If it be admitted that these inscriptions have been rightly read, we are justified in believing that kings with these names lived; but until we know not merely their names, but the order in which they reigned, and have some account of their actions, we can derive very little profit from our labour, and at present the reconstructed Assyrian history is confessedly full of gaps, long intervals separating the kings of one series from those of another, and no grounds being furnished in many instances for arranging them in one order rather than in another. In such a task ingenuity or conjecture cannot be permitted; and the longest experience will not render the historian better qualified for constructing a history without the materials for his task.

It has, however, been maintained, that if a chronological scheme is found to consist of two portions, the former of which, from the inordinate duration of the reigns or for other reasons, is manifestly undeserving of credit, while the product of both corresponds with the sum of years in a cyclical era, the chronology of the later portion may be regarded as historical. This is maintained on behalf of the Assyrian chronology of Berosus by Mr. Rawlinson, in his *History of the Five Great Monarchies of the Ancient Eastern World* (i. 192). 'The later Babylonians,' it is asserted, 'clearly contrived their mythical number so that, when added to those which they viewed as historical, the sum total should be a perfect cyclical period.' To this it may be replied that the views of ancient Babylonians cannot impart an historical character to periods of which they had no written contemporary history, that we have not the slightest ground for thinking that they possessed any such documents, and, further, that the mythical character in the earlier portion of a chronological scheme furnishes no guarantee for the historical character of the later portions, while the attempt to reach historical conclusions by ingenious conjectures applied to materials which are admitted to be imperfect and unsound resembles, in the words of Sir G. C. Lewis, 'an enquiry into the internal structure of the earth, or into the question whether the stars are inhabited,' and is an effort 'to solve a problem for the solution of which no sufficient data exist.' It may further be asserted that in a scheme parts of which are confessedly artificial we have no right to set aside all the factors in the sum except the last, and then to say that this last must represent an historical period. It was remarked by Niebuhr, in his *History of Rome*, that, 'according to the chronology of Fabius, the history from the founding to the taking of the city divides itself into two portions, 240 years under the kings, and 120 after them, or, to express it differently, into three periods, each containing ten times twelve years, twelve being the number of the birds in the augury of Romulus. This scheme was the bed of Procrustes, to which whatever was known or believed about the early time was fitted.' The first part of the task was to tabulate the kings; and as these were seven in number, this was done by making the middle of the reign of the fourth king coincide with the middle of the whole period of twenty-four years assigned to all seven. To this king a reign of twenty-three years was given, because twenty-three, together with seventy-seven assigned (as being what was called the *heroic secle*) to Romulus and Numa, makes exactly 100, and because 132, the year in which his reign was thus made to close, was the number of the astronomical years in a secle. This chronology Niebuhr pronounces to be throughout 'a forgery and a fiction.' A fabrication of a similar kind, though far less complicated and ingenious, is found in the chronology of the Æscings, or founders of the kingdom of Kent, in which the events take

place in an eight times repeated cycle of eight years, the ὀκταετηρίς of the Greeks. (Lappenberg, *History of England under the Anglo-Saxon Kings.*) Thus, twice eight years after his arrival Cerdic gains possession of the Isle of Wight; having spent thrice eight years in Britain, he takes the title of king; having reigned twice eight years, he dies, five times eight years having passed since his landing in this country.

The conclusion seems to be, that, 'if it is impossible to write history without names, it is equally impossible to reduce history to mere names,' and that from known historical events belonging to a period for which we have the acknowledged testimony of contemporary witnesses we cannot argue back to a period for which such testimony is either wanting or has been lost. It is no part of the historian's office to point out precisely where the true statements end and the false statements begin. The historian Hecatæus was as real a person as William the Conqueror; but he maintained that his sixteenth ancestor was a god. In his genealogical list therefore some names were as certainly false as others were true; but while it is impossible to draw a line of demarcation at any precise point, we know that the first link in the chain is a fiction. The history of the Peloponnesian war is true because Thucydides wrote it from his personal knowledge and after a diligent examination of those who took part in the struggle; his history of the Trojan war is a narrative of events every one of which may have taken place, but for the occurrence of which we have not the slightest evidence; but the account of this struggle, as given in the *Iliad*, we know to be unhistorical, because it abounds with impossibilities from beginning to end. Hence the persons who are said to have lived before the Trojan war become, if possible, even less historical than Agamemnon, or Phœnix, or Sarpedon; and a tabulation of the chronology of these mythical ages, or of any period for which we have not direct contemporary evidence, becomes a mere waste of labour, from which it is useless to expect any results beyond the multiplication of fallacies and fictions.

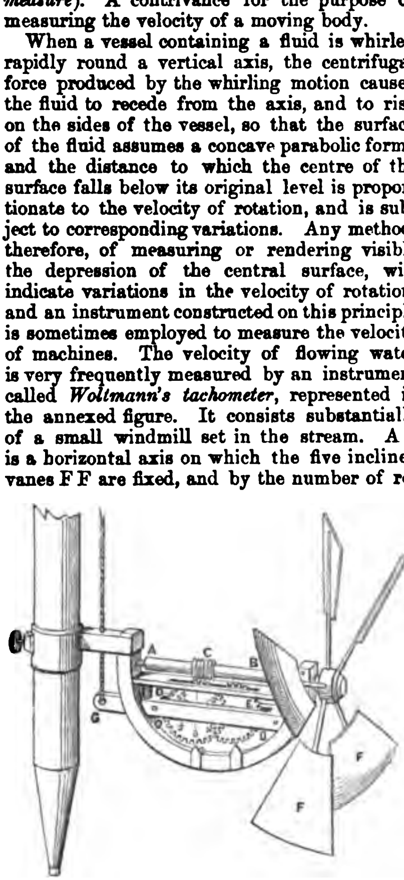
Tacamahac (an Indian word). A balsamic bitter resin, different varieties of which are attributed to *Icica Tacamahaca*, to *Elaphrium tomentosum*, and to *Calophyllum Inophyllum*. East Indian Tacamahac is the resin of *Calophyllum Calaba*. The name Tacamahac is also given in America to the resin obtained from the buds of the Tacamahac Poplar, *Populus balsamifera*.

Tacca (its Malay name). The tropical genus *Tacca*, belonging to the group of regular-flowered monocotyledons with an inferior ovary, has been considered sufficiently distinct in organisation to form the order *Taccaceæ*, though some botanists would include it in *Burmanniaceæ*. It consists of perennial herbs, with a tuberous root, radical, entire or divided leaves, and greenish or brown flowers in an umbel on the top of a simple leafless scape, surrounded by an involucre of simple bracts. The leaf-stalks of *T. pinnatifida* are plaited into bonnets by the Society Islanders, but the principal use of all the species is that of their tubers, which resemble new potatoes, and contain a great deal of starch known as South-sea Arrowroot, which is said to be far preferable to any other arrowroot in cases of dysentery. The tubers are dug up after the leaves have died away, and are rasped and macerated four or five days in water, when the fecula separates after the manner of sago. It is largely employed as an article of diet throughout the tropics.

Tacet (Lat. *it is silent*). In Music, a term denoting that through the movement to which it is affixed in any part, that part is to lie still or be silent during its performance.

Tachometer (Gr. τάχος, *speed*, and μέτρον, *measure*). A contrivance for the purpose of measuring the velocity of a moving body.

When a vessel containing a fluid is whirled rapidly round a vertical axis, the centrifugal force produced by the whirling motion causes the fluid to recede from the axis, and to rise on the sides of the vessel, so that the surface of the fluid assumes a concave parabolic form; and the distance to which the centre of the surface falls below its original level is proportionate to the velocity of rotation, and is subject to corresponding variations. Any method, therefore, of measuring or rendering visible the depression of the central surface, will indicate variations in the velocity of rotation, and an instrument constructed on this principle is sometimes employed to measure the velocity of machines. The velocity of flowing water is very frequently measured by an instrument called *Woltmann's tachometer*, represented in the annexed figure. It consists substantially of a small windmill set in the stream. A B is a horizontal axis on which the five inclined vanes F F are fixed, and by the number of re-



volutions made by the axis in a given time the velocity of the stream is determined. The axis has a few turns of a screw C formed on it, which work into the wheel D, which in its turn works the wheel E or any other train of wheel-work, and by this wheel-work the number of

revolutions is recorded, and is read off by the aid of suitable figures on the sides of the wheels. The entire instrument is screwed to a staff having a tin vane attached to it to enable it to be kept opposed to the current, and in order that the wheel-work may revolve only during the time of observation the wheels are carried in a hinged frame G O, by tightening a cord at the end of which the wheel D is brought into gear with the screw C on the axis, whereas by relaxing the cord the axis runs loose without acting on the wheels. The principle of this machine is similar to that of the patent log by which the speed of vessels is measured.

Tachyaphaltite (Gr. ταχύς, *quick*, and ἅφαλτος, *springing off*). A mineral of a dark reddish brown colour which is found in short thick prisms in the granite veins of Krageroe, in Norway. It is probably an altered Zircon.

The name has reference to the tendency of the mineral to fly off from the gangue when struck.

Tachydrite (Gr. ταχύς, and ὕδωρ, *water*). A very deliquescent salt, resembling Carnallite, which occurs in roundish masses of a yellow colour in the compact Anhydrite of Stassfurt. It is a hydrated chloride of calcium and magnesium.

Tachydromians (Gr. ταχυδρόμος, *fast running*). The name of a family of wading birds, of which the genus *Tachydromus* is the type. The term is also applied to a family of Saurian reptiles by Fitzinger, and to a family of Dipterous insects by Mirgen.

Tachydromus (Gr. ταχυδρόμος). A subgenus of *Lacertidæ*, differing from the true lizards in having a very long body and tail, with their fore legs very distant from the hind legs, and the back covered with scales similar to those on the belly. They are found in the Indian islands and China, and run with great velocity; whence their name of *swift lizards*.

Tachygraphy (Gr. ταχύς, and γράφω, *I write*). One of the many names of Greek derivation which have been given to the art of short-hand writing. [STENOGRAPHY.]

Tachylite (Gr. ταχύς, and λίθος, *stone*). A kind of Isopyre of a velvet-brown or black colour, found on the Säsebühl, near Dransfeld, and at Höllengrund, near Münden, forming small masses in Basalt and Wacke. It is a silicate of alumina and protoxide of iron. The name has reference to its rapid fusibility.

Tack (Gr. τάσσω, Ital. attaccare, Fr. attacher, *to arrange* or *fasten*). In Naval language, the weather clue or corner of a course, as also of any sail set with a boom or gaff, and of a flag. Also, the rope by which such clue is extended: thus, the *main tack* is the rope by which the tack or weather clue of the mainsail is drawn down to the ship's side.

A ship is said to be on the *starboard tack* when she is close-hauled, having the wind on the starboard side; and on the *port tack* when the wind is on the port side. *To tack* is to change from one tack to the other by bringing the vessel's head to the wind, and shifting the tacks of the sails from the one side to the other.

Tacking. In Law, a right which mortgagees possess in some cases of consolidating their securities. Thus, if there be three successive mortgages on the same estate, and the third mortgagee advanced his money without notice of the existence of the second mortgage, he may take a transfer of the first mortgage, and hold the legal estate which he thereby acquires until both his charges are paid off, thus *squeezing out* the second mortgagee. This doctrine prevents any charge on land except legal first mortgage being a really satisfactory security.

Tackle (Dutch takel). A simple tackle consists of one or more pulleys rove with a single rope. The rope is termed a *fall*. The pulleys are called *blocks*; the shell, or frame, contains the *sheaves* of the pulley which turn on a pin. When a tackle is in use, one end of the fall is made fast, and called the *standing end*; the other is hauled upon, and called the *running end*. *Overhauling* a tackle is separating the blocks; *fleeting* blocks is bringing them close together by hauling on the fall. Wooden blocks are generally bound on the outside, in the direction of their length, with a grummet, which is called the *strap* of the block. If this strap be continued so as to form a tail, the block is called a *tail* or *jigger block*, and a tackle with its movable block so furnished is called a *jigger tackle*. Bothway's patent blocks are now much used; they are iron strapped, the pin is better supported, and of smaller diameter; they have iron swivel-hooks.

The following are the principal points to be attended to in the use of tackles: 1. The condition and strength of the straps, hooks, and cordage. 2. That the fall is free from kinks and turns, and enters freely into the grooves of the sheaves. 3. The nature of the fastenings of every kind, which must be such as to insure security. 4. The proper stoppering the fall when necessary. [STOPPERING A FALL.] 5. The prevention of accidents by men treading on or striking the fall when taut. 6. The position of the men, which should be such as to insure their safety in case of accident to the tackle.

The chief simple tackles used are a whip; whip upon whip; gun tackle; luff tackle; gun tackle; but many other combinations of pulleys are used. The increase of effect produced by any simple tackle is represented by the sum of the returns of the fall, which act immediately upon every movable block in it.

In a combination of tackles, where one acts on the running end of another, the result of their combined actions is found by multiplying together the values of the several simple tackles. It must be borne in mind, that the use of tackles affords an increase of power only at the expense of time.

Tacsonia (Tacso, its Peruvian name). A genus of ornamental shrubby climbing *Passifloraceæ*, having the general appearance of

Passiflora, and the same structure of stamens, pistil and fruit, but differing in the great length of the cylindrical tube of the calyx, which is furnished with two crowns, one at the throat and the other near its base. In *T. manicata*, a very handsome species, the tube scarcely exceeds in length that of a passion-flower. The species are natives of Central America and the West Indies. The fruit of several of them, as of other *Passifloraceæ*, viz. *T. mollissima*, *tripartita*, and *speciosa*, are eaten.

Tactical Point. In War, any point on a field of battle which may impede the advance of an enemy to your attack, or may facilitate the advance of your army to attack the enemy. *Tactical decisive points for offence* are all those which, when occupied by your army, will enable it to make an attack on the enemy the success of which would be decisive on the issue of the engagement; or those in possession of an enemy which will enable him to frustrate your attack on any other point of his position, or to intercept your line of retreat if repulsed. Reversing these conditions, we have *tactical decisive points for defence*. The flanks and most advanced salients of the position are in general the most decisive points.

Tactics (Gr. τακτικός, from τάσσω, *to arrange*). The science of moving troops in the actual presence of and contact with an enemy. The chief object is to place in action at the most important points of attack a force stronger, either numerically or by advantage of position, than that of the enemy. [Battle; Strategy; War.]

Tactics, Naval. The expression *naval tactics* is commonly understood to relate to the attack or defence of fleets or single ships; but as tactical manœuvres are necessarily practised also in keeping any number of ships together, whether for hostile or other purposes, the subject, in fact, includes all considerations relative to the closing or separating of vessels at sea. In the days of sailing fleets, very elaborate rules were laid down for the management of ships, so that each should avail itself of the wind, without taking it from a neighbour, and so on. The introduction of steam has now made ships in great measure independent of the wind. Prescribed tactics would therefore be an anachronism, and the motions of each fleet in action must be regulated by the plan of the commander-in-chief based upon the actual circumstances of the time. [Ram.]

In action, it appears to have been the custom to endeavour to engage the enemy's whole fleet, ship to ship. This, however, was, in most cases, easily avoided, and actions were consequently often indecisive. The circumstance of Lord Rodney's passing through the French fleet on the 12th of April, 1782, seems to have drawn attention to the principle of separating the enemy's fleet into portions which might be attacked in detail. The merit of suggesting the breaking of the enemy's line on this occasion has been attributed to Mr. Clerk of Eldin, author of a work on Tactics which appeared at the time, but the manœuvre had been already treated in French and Spanish works on Tactics. One of the most striking applications of the principle was exhibited in Lord Nelson's attack at the battle of the Nile.

At the present day, when fleets consist of ironclads and rams, all armed with monster artillery, the prevailing tactic is naturally to try to keep out of the way of being hit or run down, a proper precaution, since to be run down by a ram is to be almost certainly sunk. Hence, fleets in action require far more space than formerly.

Among the works on Tactics may be noticed, *Tactique Navale*, by the Count Morogues, which was considered an improvement on Le Père Hoste's work; *Tactica Naval*, by Salazar; and Mr. Clerk of Eldin's *Naval Tactics*, above quoted. Much information is contained in Admiral Ekin's *Naval Battles*; and remarks on the tactics of single actions are found in Sir Howard Douglas's *Naval Gunnery*. Some other works on the subject will be found in any good catalogue of naval books.

Tactinvariant. The invariant which, equated to zero, expresses the condition that two quantic curves or surfaces touch each other. A purely algebraical definition extending to quantics in general could easily be given. The *reciprocant* of any quantic, i.e. the function which, equated to zero, expresses the condition that the line $x\xi + y\eta + z\zeta$ touches any curve, is a tactinvariant, as well as a Contravariant.

Taction (Lat. tactio, *a touching*). In Geometry, the same as *tangency* or *touching*. [Tangent.]

Tacuari. The South American name of certain species of the Euphorbiaceous genus *Mabea*, whose hollow shoots are used as tobacco-pipes.

Tænia (Lat.; Gr. ταινία, *a fillet*). A genus of intestinal worms, commonly called the *tape-worm*. The principal tape-worms infesting the human body are: the *Tænia lata*, Linn., now the type of the genus *Bothriocephalus*—this rarely occurs in Great Britain; the *Tænia saginata* or *mediocanellata*, endemic in Abyssinia and Caffraria, occasionally occurring in England; the *Tænia solium*. When this worm infests the bowels, it often produces a variety of anomalous symptoms, and is very difficult to get rid of. A great number of specifics have been recommended for the cure of tape-worm, some of which seem to possess the power of destroying the creature, such as oil of male fern, Kousso (*Brayera anthelmintica*), &c. The embryo of *Tænia* is excluded from the egg as a bladder-worm or hydatid, and is usually introduced, as such, with the meat of the animal so infested, into the human bowels. Thorough cooking of meat is the proper preventive. [Entozoa.]

Tænia. In Architecture, the lintel above the architrave which separates it from the frieze, in the Doric order.

Tænioids (Gr. ταινιοειδής, *like a riband*). The name given by Cuvier to a family of

Acanthopterygious fishes, comprehending those which have a flattened ribbon-shaped body; also the name of a family of Sterelminthoid intestinal worms, of which the tape-worm (*Tænia*) is the type.

Tafelspath. [TABULAR SPAR; WOLLASTONITE.]

Taffety. A thin glossy silken fabric, formerly much used in England. It is extensively used on the Continent for window curtains.

Taffia. [TAFIA.]

Taffo. A manure made in China, composed of night soil mixed up with clay and formed into cakes which are dried in the sun.

Taffrail (Dutch taffereel). The uppermost rail of a ship's stern.

Tafga. The fragrant North African *Rhaponticum acaule*, which has the violet-like odour of *Acacia Farnesiana*, the Cassie flowers of the perfumers.

Tafia or **Taffia** (Fr.). A variety of rum prepared in the West Indies by the fermentation of the molasses of cane sugar.

Tages. An old Etruscan divinity, who is represented to have sprung as a beautiful boy from the earth which a ploughman had furrowed too deep. Tages at once taught the Etruscans to foretell from the flight of birds what was to happen, and immediately afterwards he died. Hence he was worshipped as the inventor of augury. [AUGURS.] A collection of his prophecies was preserved in the books of Tages.

Tagetes. The showy annuals cultivated under the names of African and French Marigolds are the most familiar representatives of this genus of *Compositæ*, the species of which are natives of Mexico, Peru, and Chili, but are also grown in China and India, and in some parts of the latter country are considered sacred flowers. The scent of the common species is strong and offensive, but the continuous flowering *T. tenuifolia*, with very finely cut leaves, has a more agreeable balsamic smell.

Tagilite. A hydrous phosphate of copper of an emerald-green colour, found in fungoid or botryoidal masses, at Nijni-Taguilsk, in the Ural, on Brown Iron-Ore.

Taglia (Ital.). In Mechanics, the name given to a particular combination of pulleys. 'The taglia consists of a system of fixed pulleys collected in one common block, and also of a system of movable pulleys in a separate block, to which the weight is attached, with one string going round all the pulleys, and having one of its ends fixed to a point in the system, and the other end going from one of the fixed pulleys drawn by the power.' (Venturoli's *Mechanics*, by Cresswell.) Sometimes several taglias are combined, so that one acts upon the other; the system is then a *compound taglia*. [PULLEY.]

Tagliacotian Operation. The operation for the restoration of the nose, the *Rhinoplastie* of the French. The merit of inventing this operation is usually given to Tagliacotius, a Venetian surgeon, who wrote upon the subject in 1598, and proposed the replacement of the deficient organ by an artificial nose cut out of the skin of the shoulder or arm. A supposed modern improvement consists in having recourse for the new materials to the skin of the forehead, out of which a triangular piece is so cut that it may retain connection at its apex, which is downwards, and so admit of being twisted or turned down to form the artificial nose by adhesion to the recently cut surfaces of the truncated organ. It appears that this operation was practised in India from time immemorial, and that it was also not uncommonly resorted to by the Italians, and especially the Romans, among whom the loss of the nose was a punishment of not unfrequent infliction. (*An Account of Two Successful Operations for restoring a lost Nose*, by J. C. Carpue, London 1816; Liston's *Practical Surgery*, London 1837; and Cooper's *Surgical Dictionary*.)

Tagus (Gr. ταγός). In Ancient Greek History, the title of the president of the Thessalian confederacy.

Tail (A.-Sax. tægl). In Architecture, the bottom of any member, or of a slab, or tile. A *tail trimmer* is the trimmer next the wall, into which the ends of joists are inserted in order to avoid the flues. To *tail in* anything is to fix one end in the wall, so that the leverage exercised by the projecting part should be counteracted by the weight above it.

Tail. [FEE TAIL.]

Tail Estate. In Law. [FEE TAIL.]

Tail, Reproduction of. When the tail of lizards, newts, and salamanders is severed, a new tail is commonly developed; but instead of its being segmented into a series of vertebræ, the notochord merely developes an undivided and styliform osseous covering.

Tail-pieces. In Printing, ornaments, in wood or metal, placed in short pages, partly to fill up the vacancy. [FAC; HEAD-PIECES.]

Taille (Fr. tailler, *to cut* or *slice*; a portion taken out of an estate, as in English an estate tail: the modern Latin form is tallia or tallagium). In Ancient French Jurisprudence, any imposition levied by the king or any other lord on his subjects. The *royal taille*, in old France, which was the impost commonly understood under the general name, was a personal or rather mixed contribution, from persons not noble or ecclesiastical, or enjoying certain other exemptions, imposed according to their supposed ability, and measured by their goods. As falling on the agricultural class, it is described by Adam Smith as 'a tax on the supposed profits of the farmer, which they estimate by the stock which he has upon the farm.' (Book iii. ch. ii.) In Languedoc, and one or two other districts, the taille was real, i.e. imposed on land and goods. This tax was rendered annual and permanent in 1445. The exceedingly unfair and oppressive nature of the taille was one of the causes which led to the French revolution. [ROTURIER.] The *real* taille is now replaced by the *contribution foncière*, and the personal by the *contribution personnelle et mobiliaire*.

Tailloir (Fr.). In Architecture. [ABACUS.]

Tailzie or **Entail.** In Scottish Law, this term signifies, in general, any deed whereby the legal course of succession is cut off and an arbitrary one substituted. But, more strictly, a deed of tailzie is one framed in terms of the statute 1685, c. 22, and designed to secure the descent of an heritable estate to the series of heirs and substitutes called to the succession by the maker of the tailzie. The principal difference between Scottish and English entails lies in the absence of any provision, in the law of the former country, similar to the fictions of fines or recoveries in the latter, whereby parties in possession were enabled to cut off the entail. Several statutes have been passed since that of 1685 to give heirs of entail in possession certain liberties which they could not otherwise possess; of which the 'Rutherford Act' (1848), 11 & 12 Vict. c. 36 (amended by 16 & 17 Vict. c. 14), is now the ruling statute, giving power to heirs born since its date to disentail on majority, and otherwise relaxing the law as to those already born.

Tal or **Tala.** An Indian name for the Palmyra Palm, *Borassus flabelliformis*.

Talapoins. The title, in Siam, of the priests of Fo, who are called in China, Seng; in Tartary, Lamas; and by Europeans, Bonzes.

Talbot. A hunting dog, between the hound and beagle. The term is now almost obsolete.

Talbotype. A photographic process so called in honour of its inventor, Mr. W. A. Fox Talbot. [PHOTOGRAPHY.]
